and groups of a mixed lot of these hybrids are at once interesting and very beautiful. The stately flower-stems and large, showy yellow blooms of the species allied to Thapsus mark them as wild garden flowers, and where the soil is rich and sufficient no better or showier plants can be grown. In the rockery I find them quite indispensable, and encourage rather than prevent their seeding amongst the mixed shrubs, &c., in the vicinity of the rock garden. They are also good

BORDER PLANTS, and rarely, if ever, fail to reproduce themselves freely from self-sown seed. *Verbascum Chalcid*, or *V. vernale*, is one of the true perennial species at present in cultivation. This may apply only on warm soils. It often attains to 10 feet in height, and when well grown forms a most imposing group. The leaves, very large and bright-green, come up early and are very effective. The flowers are large, yellow, with purple filaments, very striking, and last a long time in good condition. For the back row of mixed borders, for isolated groups, and amongst mixed shrubs this species is very effective, and as it gives little or no trouble, is certainly one of the best for general purposes in a garden. Of this there are two hybrids, semi-lanatum and *Frynianum*, both showy.

Native of Europe. *V. crassifolium*: A very distinct and charming species, with yellowish tomentose woolly leaves and robust spikes of large yellow flowers. It is a native of Portugal, and one of the few species that will do in a light sandy soil. *V. cupreum*: A species nearly allied to *V. phoeniceum*, quite hardy, and a true perennial. It has cordate, wrinkled leaves and copper-coloured flowers, very quaint and interesting. It is perhaps a hybrid of *V. phoeniceum*, flowering May to August. South Europe. *V. olympicum*: A gigantic *V. Thapsus*, and one of the grandest of the genus. The flower-stems in strong specimens attain to from 6 feet to 10 feet in height, the flowers very large, rich yellow, the woolly leaves forming large rosettes. A biennial from the Orient. *V. phoeniceum* (see p. 153): A perennial species, and one of the very best for mixed borders in small gardens. It is very variable, there being white, violet, lilac, rose, deep violet, and purple-flowered varieties. It continues flowering from May to August, and when doing well is a very striking plant. Native of South Europe. *V. phlomoides* (the large woolly-leaved Mullein) is a biennial and very fine in groups. The flowers are large, pale yellow, with purple filaments. Robust specimens reach a height of from 6 feet to 8 feet. South Europe. *Australe* and *Sartori* are well-known and desirable varieties. The pyramidal Mullein (*V. pyramidalum*), with its candelabrum-like branches of bright-yellow flowers, is a very effective border plant. It is a perennial, grows in rich soils, and is very effective, with its towering flower-stems and huge rosettes of crisp leaves. Native of the

OUR READERS' ILLUSTRATIONS: *Verbascum nigrum* var. *album*. Engrave for GARDENING ILLUSTRATED from a photograph sent by Miss Wolley Dod, Edge Hill, Malpas, Cheshire.

indeed, the only way if this be desired is to grow one or two specimens only in a garden, and these as far away from each other as possible. Many of the species and varieties are, as a matter of fact, considerably enhanced by

its candelabrum-like branches of bright-yellow flowers, in a very effective border plant. It is a perennial, grows in rich soils, and is very effective, with its towering flower-stems and huge rosettes of crisp leaves. Native of the

Caucasus and Siberia. All the Verbascums are worth a place in the garden if only they could be kept true, but in the absence of this, the hybrids, which are always showy and in some few cases differ little from the types, may well be grown. Amongst the species to be noted as worth procuring should opportunity occur are *V. macranthum*, *V. Theopasti* and hybrids, *V. longifolium*, *V. virgatum*, *V. Blattarii* and *blattarioides*, *V. niveum*, *V. Boerhavi*, *V. sinuatum*, *V. nigrum* (see p. 159) and *var.*, *V. orientale*, &c. All may be readily raised from seed, and are well worth taking care of. D.

3728.—Plants for a border.—You ask an important and interesting question. There are many pretty hardy plants that are not sufficiently thought of, although with fragrant leaves. I do not care for variegated plants, as a rule, but a few are good. As regards the fragrant-leaved plants, one must have the Lavender, which it is unnecessary to describe. The soil in which it is planted should be light and the position sunny. One of the most charming bits of planting I remember was a border where the sweet-smelling leaved plants were grouped together—the Lavender, Rosemary, and other things. The Rosemary is a very hardy, shrubby plant, and grows in common soil, if dry and warm so much the better. When in flower it is very pleasing. Then you may choose the Myrtle, which, however, in cold spots is likely to get hurt in the winter. The Southernwood, or "Old Man," as the children call it, and Sweet Gale (*Myrica Gale*) has fragrant leaves. It grows into a bush, and must have a moist place. Then there is also the Sweet Fern-leaved Gale (*Comptonia asplenifolia*), which may be noted for its fragrant foliage. Thymes in variety are of value. You can have the Wild Thyme (*T. lanuginosus*) and the Golden Thyme, which is very pretty when seen in a good compact condition. *T. serpyllum album* (white) and *coccineum* (magenta) are very beautiful. The leaves of the *Chrysanthemum* are fragrant, and the Gum Cistus also. Such kinds as *C. ladaniferus* deserve to be more often grown than is at present the case, its leaves, when rubbed against, giving off a rich fragrance. They must be grown in a sunny position, in light soil, then a bed of them forms a good feature, as the flowers are attractive. In severe winters they are likely to get hurt. I have selected a few of the more pronounced hardy plants for their variegation. One could make a long list if those with silvery leaves were included, and you will find in Robinson's "Hardy Flowers," published by Macmillan and Co., a list of the finest kinds. *Alyssum saxatile variegatum* is a variety of the Rock Madwort, but it is not so brilliant as the type, which is one of the best flowers of spring for effectiveness. A rare variety of *Cineraria maritima* named *aurea marginata* is a very finely-marked variegated plant, the leaves mottled with creamy white and glaucous colour. It is very distinct and not weak. I have seen it in nurseries, but probably is rather expensive as yet. The variegated variety of the Crown Imperial is a slow plant, the leaves being margined with golden-yellow colour, the flowers curved red; and a very useful variety is *Daactylis glomerata variegata*, which is a beautiful plant, finely variegated, easy to grow, and not "miffy," like many such things. The Funkias supply a large number of variegated kinds, varieties of *F. lancifolia*, *F. ovata*, etc., these of the first-named in particular being of note. *Alba marginata* is one of the best, and *Hoteia japonica variegata* is very distinct, the leaves well marked, whilst you may also include the variegated variety of *Iris fetidissima*, *I. pseudocorus*, *Ophiopogon Jaburum variegatum*, *Sedum Sieboldi variegatum*, very pretty, but not so robust as the type, and the Golden Money-wort, *Lysimachia Nummularia aurea*, a big name for a little plant. It is one of the finest variegated hardy things grown, its leaves are pure golden-yellow without a trace of green, and the growth is robust. The golden-leaved variety of the Valerian is very bright in the spring, making quite a patch of colour on the border. The above list will form a very good beginning to your collection of fragrant and variegated-leaved plants.—C. T.

Thinning annuals.—A word of advice to those who have many annuals in their garden is to thin them out well, so that each plant has

sufficient space for its full development. It is impossible to get well-grown plants if they are deprived of a proper shade of light and air; but in many, I may say the majority, of gardens they are so crowded up together that the growth is naturally weakly, straggling, and the flowers few in number. This is not the fault of the plant, rather of the way in which it is grown. Few classes are more gay than annuals when they are cultivated properly, given a reasonable amount of space, and a fairly good soil. Then the results are very different from those that one sees in gardens. Thin sowing is very important. There is much waste of seed through the careless way in which it is sown, and the seedlings commence their life with a weakly growth. Always bear in mind when growing annuals, firstly, the importance of thin sowing and letting each plant have its fair share of room. Ordinary garden soil will suffice for most annuals.—V. C.

ORCHIDS.

CYPRIPEDIUMS OF THE "CONCOLOR" SECTION.

SEVERAL enquiries have come to me about these Orchids, showing that there is no lack of interest in them. "J. T. H." says he cannot grow the species named above to his satisfaction, wants to know where it comes from, and all about it, more especially how to get the flowers up upon a longer stalk? Another query is from "C. W. C.," which asks for the proper treatment of *C. Godefroyi leucociliatum*? Just this variety I do not know; indeed, I do not think it is an acknowledged variety. Then comes another enquiry from "O. Murdock," asking for some instructions how to do *C. nivenum*? So that I cannot do better than to answer all under the same heading. The plants in this section are all Orchids belonging to the warmest regions, requiring under cultivation a high temperature and a moist atmosphere; in fact, I should advise them to be kept in a house that does not at any time fall below 63 degs. of heat. They are plants that affect the limestone districts only, and, therefore, I always recommend my friends to use limestone in growing them, as I am sure where this has been done in a proper way, the plants not only grew free, but they will throw up their flowers on a much longer stem; but the worst of it is so few people appear to use this material with any amount of freedom, apparently living under the impression that limestone or anything approaching this in consistency is death to the Lady's Slipper. One young friend, whom I had told to use a good bit of limestone with the soil, professed to follow my advice; some time afterwards, when I called to see him, he said his plants did not get on in spite of what I had told him. Upon knocking a plant out, I found he had placed three pieces of old mortar, about 2 inches in length, round in the soil near the sides of the pot. Now this is what so many call using lime-rubbish or limestone extensively; but this is just like a chip in porridge—it will do neither good nor harm. I would use for them an abundance of drainage, and this to be composed of limestone or old mortar-rubbish; upon and in this the roots should be placed; and for soil use loam, peat, and chopped Sphagnum Moss in about equal proportions, taking care that the two former have the greater part of the fine soil extracted, and use with this quite one part of old mortar. Potted in this way, you will find the plants thrive in a better manner. In one year it will not have the effect of lengthening the flower-stalk much, if any, but in the second flowering you will perceive a difference, which will go on increasing if the temperature and the moisture is maintained at the proper condition. The following four kinds may be included in this section, and all will thrive well if potted on the principle laid down above, when, if heat and moisture be maintained, they will soon make roots in abundance, and will flower in profusion.

C. BELLATULUM: This very fine form was introduced by the Messrs. Low and Co., and it is undoubtedly the finest of its section. I am not in a position to give its native locality, for the necessities of the trade still keep it a secret. It is a magnificent grower, having large leaves of a deep-green, more or less mottled with pale

green on the upper side, but beneath they are of a uniform dark-purple; the scape has hitherto been exceedingly short, bearing usually but a single flower; but this is some 3 inches across. The ground colour is usually white in front, sometimes, however, it is soft-yellow and rosy-yellow, boldly spotted with deep-purple; the petals are very large, depressed; the lip is very much in shape like a plover's egg, and more sparingly spotted than the other parts of the flowers. This plant has not yet been seen in its beauty, because the flowers have not been thrown up sufficiently high to show them off effectively; but this, I am of opinion, arises from bad culture, but I have seen a plant with a scape some 3 inches high, giving an indication of what it will prove to be when properly grown.

C. CONCOLOR.—This, the first known of the race, was first found in Burmah by the Rev. Parish, and some four or five years afterwards living plants were obtained by the Messrs. Low and Co., and it has become known at widely distant places, so that it has been found to vary considerably from different localities, and several varieties have been recorded. The leaves are thick and fleshy, the colour beneath being reddish-purple, but the ground colour above is deep green, mottled more or less with greyish-green. The scape is, in general, very short; in fact, less has been done to improve this defect than with any of the section, and I should be glad to know from the collectors if this feature is observable with it when growing in a state of nature. The flowers are borne singly or in pairs, the ground colour being pale-yellow, thickly speckled with small dots of crimson.

C. GODEFROYI.—This is a plant for which we all have to be thankful to my friend, M. Godefroy, of Argenteuil, near Paris, who first introduced the plant into French gardens. It comes very near to *C. bellatulum*; but it is less robust in growth, and its flowers are smaller, and it is less boldly coloured; but it is, nevertheless, a most beautiful plant, deserving of the close attention of all growers of Lady's Slipper Orchids. The leaves are some 5 inches long, sometimes shorter. They are strap-shaped, rich dark-green above, mottled with pale green, whilst beneath they are of a reddish-purple. The scape is usually one flowered, the flowers large, considerably more than 2 inches across. Their ground colour is white, sometimes creamy-white, and the pouch-like lip has frequently a more decided tinge of cream colour, and they are more or less profusely spotted and blotched with bright purple. M. Godefroy has expressed it as his opinion that this plant is identical with *bellatulum*, but the latter plant is fully double the size of it, and whilst I admit it comes close to it, I cannot but think them quite distinct. This plant comes from some of the limestone islands in the Gulf of Siam.

C. NIVENUM.—The first appearance of this plant was as it laid upon the table in Messrs. Stevens' rooms at Covent-garden, and it was catalogued as *C. species*, and nearly everyone took it for *C. concolor*, and as the last-named plant had been imported in some quantity, none wanted it, and it was sold very cheaply; but when it flowered, the present snowy-white species was revealed. It is the smallest growing plant of the series, the leaves being of a very deep-green above, speckled and freckled with pale greyish-green, and beneath they are dull-purple. It is curious enough that this plant has produced a scape taller than the others, frequently 6 inches high, and I have seen it more, and sometimes two flowers are produced upon a stem. These flowers are snowy-white, sometimes freckled with purple. It is a perfect gem. These plants all require to be well exposed to the sunlight. MATT. BRAMBLE.

3749.—Pronunciation of Clematis.—In Johnson's "Gardener's Dictionary," Chambers' "Etymological," Nuttall's "Standard," and in Webster's "English Dictionary," it is in each case pronounced with the accent on the first syllable—thus, Clemá-tis. Sir Walter Scott, in "The Lady of the Lake" gives it the same accent—"The Clematis, the favour'd flower, which boasts the name of Virginia Bower."—L. O. K.

3832.—Sewage in the garden.—I have a cesspool from which I draw very freely for liquid manure, without adding any other waters. But I think all such places should be ventilated by some means, to allow the gas to escape. My cesspool is permanently ventilated by means of a conducting pipe.—SOLVITA

TREES AND SHRUBS.

A HOP COVERED ARCHWAY.

The Common Hop is a capital plant for covering an archway, and it makes a happy contrast with Ivy and Clematis Jackmani and its varieties, the mass of deep-green leaves intensifying the colour of the rich abundance of deep-blue flowers. Nor is its charm confined merely to summer, but as autumn approaches the plant then carries its rich clusters of golden-yellow Hops, and receives additional beauty of no mean kind. We can judge of the rich beauty that a common climber can give when once it has become established by a glance at the illustration. There is another kind called the Japanese Hops which has been much used for covering arbours, and trellises. The growth made is surprisingly rapid. Those who have not yet heard of it should give it a trial, and though resembling the common type, it has no commercial value whatever. The bunches of flowers are larger, and, therefore, the plant has an advantage for the garden. T.

Japanese Maples.—These beautiful shrubs are hardy, although there seems to be a

colour, which gives way to deep blood-red as summer approaches. A good plant of it is of a full rich colour and striking appearance throughout the season. Another very fine variety of *A. palmatum* is *septenlobum elegans purpureum*, the leaves deep-purple crimson, a fine effective colour, richer than in the type itself. Exquisite in form is the rich-crimson leafage of *A. p. dissectum atropurpureum*, a lovely variety for its deep colour and finely-divided foliage, and a note may be made also of *palmatipidum*, the leaves delicatogreen, and like a Fern in character. Of a different character to the foregoing is *A. japonicum*, which has deeply-lobed leaves of a light-green colour, but in the variety *aureum* they are yellow, the footstalks and veins of a rose-coloured shade. All the above are hardy, except possibly in the bleakest spots in England, and comprise the finest of the dwarf *Aceras*. As yet they do not seem to have got very popular, chiefly, no doubt, from the idea that they are in some measure tender.—V. C.

Azalea mollis.—This fine *Azalea* is in fullest beauty early in May, and a large group of the shrubs present a glorious mass of brilliant and varied colours, ranging from bright-carmine to soft yellow. *A. mollis* is a native of Japan

and keeping them in the greenhouse. They will flower well, and after they have done blooming should be pruned back and taken reasonable care of. When all fear of frost is over plant them out, not in too sunny a spot, and water them occasionally. This *Azalea* is one of the most useful shrubs to bring on into bloom gently under glass that an amateur can have, and a great range of colour is got from seedlings.—C. T.

3744.—Shrub seeds from New Zealand.—You do not give names of shrubs, but the best way is to sow the seeds in 48 or 6-inch pots filled with a light soil, well cracked, and place them in the greenhouse. They may be some time before they germinate, and give water very cautiously, just keeping the soil moderately moist and no more. When the seedlings appear pot them off into small pots and keep them in the greenhouse. Take care not to disturb the soil more than necessary, as sometimes the seed germinates very irregularly.—C. T.

3772.—Trees for a garden path.—There is a fine selection of things to choose from. Very beautiful are the Thorns (double crimson), Paul's Scarlet, which succeed well in gardens, or if you require an arbour, get the *Wistaria sinensis*, and, if it is not too expensive, the white variety, which was recently recommended in GARDENING. They would form a fine border of flowers at this season of the year, or you could have many charming things, such as the Honey-suckles in variety, some of the prettier Vines, Dutchman's Pipe (illustrated in GARDENING, May 13, 1893), Clematises, particularly the beautiful *C. montana*, *C. Jackmani*, and its varieties; but many of Roses are delightful—Gloire de Dijon and others. Boys will not play pranks much unless the flowers hang over the main path; they seldom get into gardens if it is too risky. You could train the branches of the Laburnums over with good effect. You might also have *Bigoneis* or *Tecoma radicans* (the Trumpet-flower), the flowers orange and scarlet. It is very graceful, and a pleasing climber when in full bloom. Such a tree as *Pyrus nana floribunda* or *spectabilis* would be very charming. Both are of graceful habit, and in May wreathed with flowers, and another tree not too often seen, but well adapted for the position mentioned, is the Rose Acacia (*Robinia hlepida*), which is a delightful small tree, well adapted for a garden of limited dimensions. It has larger leaves than the other kinds, and a profusion of rose-coloured flowers in early summer, a long succession being maintained until the autumn. Give the tree a fairly sheltered spot, at least, the most sheltered corner in your walk, as the stems are apt to break quickly. I should get the *Wistarias* or some of the fine Vines, and one of the best is the Isabella Grape (*V. labrusca* or *V. Thunbergii*), which has large foliage that changes to deep-crimson towards the autumn.—C. T.

3733.—Box edging.—When planting Box edging it ought to be cut square across at the top, so that a perfectly level edging is assured. In that case nothing more in the way of clipping is required until April of the following year. In the present case I should advise that the Box be cut at once to within 3 inches of the soil. Watered growth is made afterwards will be level.—S. F.

—You may clip the Box edging within the course of the next few weeks, and we should, as the edging has only recently been formed, give occasional waterings, which will assist it greatly.—C. T.

—The Box should have been trimmed before planting, and then any little irregularity in length could have been put right in planting. Run the shears over it when there comes rain, and get it into shape, but do not cut into the hard wood.—E. H.

3734.—Hillias.—It has been a bad time for recently moved evergreens. The only thing you can do now is to mulch over the roots and make sure they are moist, and every morning and evening sprinkle the plants overhead with a roset pot or the syringe. If this treatment had been carried out from the first they would have been safe. Possibly now it may be too late.—E. H.

3725.—Ivy covered with black fly.—The present dry weather is all in favour of the spread of aphides. The black fly will make the young leaves curl, disfiguring them, the flowers being injured. Thoroughly syringe the leaves on the underneath side with strong soap-suds, applied with some force, afterwards washing the leaves thoroughly with clean water.—S. P.

—The fly would not be injurious if merely a few shoots are affected, send a good drenching with the garden syringe. But you may rest assured, I think, that no harm will be done, and a good hosing will be helpful.—C. T.

—Black fly is injurious to everything on which it settles, and should be got rid of by the use of Tobacco-powder or liquid insecticide. The cheapest way of clearing it out is to thoroughly dress with Tobacco-powder, and the best way to keep it from coming on the wall, and wash off the dead and sickly leaves.—E. H.

A Hop-covered archway.

mistaken notion that frost quickly affects them. They grow slowly, and are dwarf, spreading out into a dense head, the colour being richer on those that are placed in moderately sheltered positions. A good group on the lawn boundaries or in association with variegated shrubs is very telling, and a few specimens of the species, which has beautiful crimson leafage that gets deeper as the summer lengthens, give delightful colour to the garden. The soil should be good, moderately light, and the position not exposed to cold, cutting winds. Those who wish to grow this class of *Aceras* will find the following varieties are quite the best for the garden, although there is a long list of kinds to choose from. I made this selection carefully, each variety possessing distinct characters, either in the fine form of the leafage or its deep, inviting colour. *Acer palmatum linearilobum* has long, deeply-cut foliage, which when young is tinged with red, but changes to green with age. It is very distinct, and stands out conspicuously from others in the collection. A variety of this, named *atropurpureum*, is an excellent companion to it. It is a beautiful shrub, the leaves when just expanding are quite of a rose-purple

but perfectly hardy in England, and now this fact is getting well known, it is reasonable to suppose that this race of *Azaleas* will be more largely grown in the future. During the past few years it has been coming rapidly to the front, and one cannot see how such a class can remain long in the background, such shrubs at this season of the year being smothered with flowers. It is noticeable that the flowers not only represent great range of colour, but individually they are of very fine form, broad, robust, and with plenty of substance. Owing to the early blooming of the shrubs, it is wise to plant them in sheltered positions, to prevent as far as possible injury to the expanding buds from frosts. A group of *A. mollis* on the outskirts of the lawn, backed with dark-green leafage, forms a brilliant picture of varied colours; the salmon shades, especially striking, are brought out by the deep-green foliage behind. A conspicuous *Azalea* late in spring is *A. altaclarensis*, the flowers of which are large, deep-orange, shot with red—a handsome and showy variety. Even those with only a greenhouse can get *A. mollis* in beauty by getting good plants, potting them up in the autumn,

The Jew's Mallow.—A very beautiful early-flowering shrub is *Kerria japonica* B. pl., which is popularly known as the Jew's Mallow. I have seen many large plants in older gardens lately; but it is a fine thing for those who have small places to grow, as it does not mind even the smoky atmosphere of the suburbs. The flowers are of a brilliant orange-yellow colour, large, and borne in profusion. A good healthy plant is quite a sheet of yellow in the spring months, and ordinary soil will suffice. Although a wall shrub—nt least, usually seen against a wall—the *Kerria* may also be grown as a bush; but it seems to succeed better against a wall.—C. T.

FRUIT.

HOW TO THIN GRAPES.

THIS detail of *Vino* culture is of considerable importance, because if the bunches were left to themselves they would certainly be spoiled. To enable the cultivator thoroughly to grasp the details of thinning the berries, and the reason for doing so, it is wise to ask the question—Why should the bunches require thinning at all? The answer being—To obtain superior fruit to that which could possibly be obtained without thinning. No matter how many bunches are produced, if the berries individually are small the crop is counted a poor one. Certainly, the fruit does not bear comparison to that managed on the right principle, when I say that to have Grapes of large size it is necessary to remove quite one third of the berries from every bunch, thus making space for the remaining fruit to swell to double the size it would attain if all were allowed to remain. The cutting away of these surplus berries constitutes the art of thinning. Experience only can teach the cultivator how much space to leave for the berries to swell to their full extent in various kinds. For instance, Gros Colman will need more room between the berries than *Mrs. Pinos*, the former being the largest berried variety in existence, while the latter is the smallest, if I except the *Frontignan* species. *Madresfield Court* is another variety to quote as requiring special attention in thinning. The berries of this *Black Grape* swell to a large size when properly managed in all respects, but there is an evil in connection with this kind when not thinned enough—that of cracking. The skin of this *Grape* is so thin and tender that the least pressure put upon it in any way results in a lack of elasticity, the skin refusing to remain intact. The result is that the berries then are spoiled. They cannot ripen off, however near they may be to it. Cracking generally takes place just at a time when colouring commences. At that period the additional space is required. In thinning the *Grapes* another point has to be considered—that of overdoing it. If too many berries are removed, those remaining cannot fill the space allotted to each. Not only is this defect a loss of weight of fruit and a loose appearance of the bunch, both when hanging on the vine or when cut. Over thinned bunches are entirely useless for exhibition, and they have a bad appearance on the dessert-dish; instead of standing up plump the berries fall away the moment the bunch is laid down, owing to want of support, and the bloom is rubbed off by the berries falling one against the other, exposing the stalk of each, which is detrimental as a perfect specimen of a bunch of *Grapes* of any kind or colour. The time to commence to thin the berries is important. Many persons leave the work much too long. It is not possible to thin a bunch satisfactorily after the berries crowd each other. In that case the bloom is certain to be displaced; as this is seen on the skin of the berry directly the berries are formed—in fact, it might be said the bloom comes with the berry. I would urge upon the operator that under no circumstances should the berries be handled or rubbed with the hair of the operator's head, because either will leave a mark upon them, and the bloom will be removed at once, spoiling the appearance of any bunch, and perhaps producing rust on the skin of the berries, which hinders them swelling to their natural size. A clean pair of VINE SCISSORS should be used, which taper at the point more than ordinary scissors do, they enables them to be pushed into the middle of the bunch, if necessary, to remove any berries.

A thin piece of builder's lath, 8 inches long and 1/2 inch wide at one end, in which should be cut a notch resembling the figure V, this space being to support any part of the bunch, such as a shoulder, when holding it for the purpose of more readily inspecting and removing badly-placed berries. The opposite end should taper to a point, as this can be more easily thrust into the centre of the bunch than the blunt end. The shoulders of the bunches ought to be supported after thinning to provide more space for the berries to swell, which increases the size of the bunches as well as the berries, rendering them also more shapely. Thin strips of bast, neatly twisted, are the best things for tying up the shoulders, one end being fastened to the shoulder, and the opposite to the wire above the bunches on which the rods and shoots are trained. Care should be taken that the shoulders are not raised above a horizontal position, or the flow of sap to that part of the bunch will be checked. I omitted to say that all *Grapes* intended for use during the winter ought to be most carefully shouldered up, as it adds to their keeping qualities by allowing more space for a free air circulation, which is one of the main preventives of damping off the berries during the winter or dull weather at other seasons. Commence to thin the bunch at the point first, cutting out with the point of the scissors all small or stoneless berries, the aim being to retain only such as those that promise to swell evenly together, which alone renders a bunch of *Grapes* perfect. It is difficult to say which berries require cutting out, and which ought to be left. A thinner who has had some experience will tell at a glance which berries will swell to their full size. The stalks which appear rough and strong are those which carry the finest berries. Those soft stalks which appear weak and bend with the weight of the berry will not produce large berries; it is often found later on that these are imperfectly fertilized, and, in consequence, are stoneless and unable to swell to full size. In the case of *Black Hamburgh*, for instance, the bunches are made up of smaller branchlets, many consisting of three berries at the point of each. As a rule, the one at the point should be left, cutting out one on each side. No berry ought to rub against its neighbour at this stage. Every one ought to have a clean space to swell in. The top or shoulder part of the bunch should not be thinned quite so severely as the point of the bunch, because more space is allowed for the berries near the main stem, where it joins on to the shoot. The bunches require a second thinning, or at least they need examining, just before colouring commences, to make sure that none of the berries are jamming each other. Some few may not be swelling evenly. These should be cut out where they are at all thick, especially in the middle of the bunch.

inexperienced often err in using boxes either too flimsy or too large for the fruit to be safely packed in. What is wanted are fairly strong shallow wooden or tin boxes that will not crush if a moderately heavy weight should be packed on the top of them. Cardboard boxes are not at all suitable for the purpose. They are too deep, too narrow, and too fragile, and the trifling saving in postal or railway charges effected by using them is often at the expense of the valuable contents. When, owing to the crushing of the fruit and consequent dissolving of the cardboard, only the lid or rather more of the original box and the label reach their destination (postmasters will corroborate my assertion that this often happens), the consignees, at any rate, must wish that less risky methods of packing had been resorted to. It falls to the lot of only a few packers to be in a position to order what light boxes they may require, but if it is not possible to have suitable boxes made, they can yet be bought very cheaply from the nearest confectioner or grocer, drawing this line at soap boxes. Nothing answers better than chocolate boxes, a common and useful size measuring 14 inches long, 9 inches wide, and 2 1/2 inches deep. Should these be too large they can easily be shortened, though if a bundle of small boxes were bought from a confectioner at one time, suitable small sizes are usually included. This kind of boxes may safely be sent by either post or rail, and, in addition to using them, I have also several strong tin boxes made especially or principally for packing Strawberries in. These are 12 inches square, and, allowing for the rim on the lid, 2 1/2 inches deep. The largest fruit grown can be packed properly in these tin boxes, each of which holds about 2 lb of Strawberries. Either these or wooden boxes to hold a single layer of fruit are preferable to any "nesting" arrangements—that is to say, cases that will hold several trays or drawers. Nor do I advise anyone to have boxes made, or to use any already in stock, with separate divisions for each fruit, but rather the contrary. Not only are divisions quite uncalled for, but it is impossible, as a rule, for the fruit to be packed in and got out of these without being damaged in some way. Strawberries can easily be prevented from bruising each other, especially if good use is made of the lids of the boxes, and it is the assistance derived from the latter that largely influences me in favour of shallow boxes, tying several of these together if need be, rather than resorting to the use of trays or drawers. Naturally, the

CONDITION of the fruit when packed has much to do with the way in which it will turn out again, and, it is almost needless to add, fruit that is dead ripe or quite soft is of little value in any case. Better the fruit be slightly under-ripe than over-ripe, not merely on account of its travelling better, but also for the important reason it is far more likely to be of good quality when eaten. It may not be possible or advisable to pack the fruit directly it is fit, and there are times when it has to be kept for several days in order that enough be available for one or more large dishes. This difficulty is best obviated not by transferring the plants to a cool house or room, this frequently checking the swelling of later fruit and not preventing the softening of the more forward, but by gathering the fruit directly it is coloured, laying it thinly in a box lined with either wadding, Moss, or wood shavings, and covering with tissue paper. If this box is placed in a cool, dry room or cellar the fruit will keep well nearly or quite a week. In any case it is advisable to either gather the fruit when it is cool and dry, or else to keep it until it has cooled somewhat prior to packing. In anticipation of packing, gather a sufficiency of large young Strawberry leaves, or better still, it obtainable, either leaves of forced Kidney Beans or young Lime leaves, the former to be flagged or softened somewhat by being placed in tin sunshine or near to hot water pipes, but the others are usually quite soft enough. Select a box or boxes that will about hold all the fruit to be packed, and well line these, sides as well as bottoms, with either a sheet of cotton wool, dry springy Moss, or the softest wood shaving or "wool," the latter being separated from the heap long enough to get rid of any woody smell that may be attached to it. The fruit must not come into contact with either of these substances, and in order

STRAWBERRIES BY POST AND RAIL.

LARGE numbers of Strawberries are grown under glass as well as in the open only to be spoiled in transit to their ultimate destination. Faulty packing is principally responsible for most of the failures to travel, and this I assert after having made every allowance for the softness of the fruit and the rough handling to which the boxes containing it are subjected. Some varieties undoubtedly travel much better than others, the fruit of Sir Joseph Paxton and Vicomtesse Héricart de Thury being among the firmest, while none are softer than Noble, yet I have had two complimentary notes early last season as to the excellent manner in which the last named arrived at its destination. One box was sent by parcels post, the other by rail, and seeing that they had to travel not less than 120 miles it was a fair test of skill in packing. As it happens, however, the distance to which the fruit has to be sent would not, in any case, nor ought to in others, make much, if any, difference in the method of packing. If Strawberry will not travel well to a great distance or over a period, say, of about twenty-four hours, it is very doubtful indeed if they would turn out satisfactorily at the end of a dozen miles, and after only an hour or two in the box. It is next to useless to write or print "fruit" or "this side up with care" on the boxes. The packing must be done well, and then the boxes, if almost immaterial whether they are handled carelessly or not. Where the

to keep them perfectly clean and sweet, cover the packing material with tissue paper; wrap each fruit so that it shall rest on and be divided by it, in a single flagged or soft leaf or portion of same, and lay the whole in closely, flatly and neatly. They can be fitted together so as to present a pretty appearance. Invert more of the leaves or young Vine leaves over the fruit, cover with paper, and on the top place a layer of packing material. On the latter the lid should shut down tightly, I might say very tightly, this effectually preventing any movement of the fruit, no matter which way upwards the box may be turned, everything in fact depending upon this pressure. Never drive a dozen nails into a lid where one or at the most two small ones would suffice, getting them out again spoiling the lid and not unfrequently some of the contents of the box. String the boxes properly and they will not be tampered with. The worst ordeal Strawberries by post can be subjected to is a long journey into the country on the back or in the bag of a postman. The same methods should be resorted to whether the Strawberries are to be packed for private use or the markets. In the latter case careful packing may make a very great difference in the prices obtained, damaged fruit being next to worthless in the markets or fruiters' shops. I hold it to be unwise to mix large and small fruit together whether they are intended for sale or otherwise, one simply spoiling the appearance of the other, and if small ones are sent let them go as much as possible for use in the kitchen. Separate the

are infested with red-spider on the leaves nearest to the main-stem are weakened for the next year's crop of fruit; the leaves in question are those from which the Vine draws its supply of food mainly. If the spider attacks the Vines before the berries commence to colour, and is not checked at once, it is impossible for the Vines to finish the crop of fruit in a satisfactory manner. There are several methods practised of checking the spread of the spider, such as making the hot-water pipes as hot as possible, and then cover them with sulphur and water, made into a thick paint. The frames of the sulphur are thrown off and fill the house, which is kept close, thus, as is supposed, suffocating the spider, but in the majority of cases this is only half effected. Often the cura is worse than the pest, as the foliage is burnt with the sulphur fumes which seriously checks the Vines. Some growers sponge the affected leaves with soapy water or Tobacco juice, but I have not much faith in this plan, as the remedy is generally only partly successful and there is a risk of disfiguring the berries in the operation, which of course would spoil them for exhibition purposes. A very good remedy, where the bunches are not required for exhibition, is to thoroughly syringe the Vines every night with clear water. The best of all remedies though is dusting the parts affected with sulphur, which, if carefully done, not only checks but exterminates the pest entirely. Upon the first sign of the presence of the spider on the underside of the leaves, place some sulphur, that of a brown colour is best, in an ordinary distributor, hold the affected leaves in the left

The insect may be destroyed in the following ways: By catching the moths, which are of considerable size, measuring sometimes 2 inches across the wings, which are white with various black spots on them, arranged more or less in lines; the bases of the upper wings are yellowish, and there is a band on the wings also of the same colour. They fly by no means rapidly. In the winter any dead leaves attached to the bushes should be carefully collected and burnt, as well as the leaves which have fallen, and any rubbish which may be under the bushes. The caterpillars may be picked off the bushes in the spring, and may be shaken off, or the leaves may be well syringed with 10 lb. of soft-soap, the extract from 6 lb. of Quassia, and 100 gallons of water; or the trees may be dusted with hot lime, sulphur, or soot when wet with dew. Make the ground under the bushes firm and smooth, so that any caterpillars which fall during any of the above operations may be easily seen and killed. These washings, &c., will equally apply to the grubs of the Saw-flies. The Saw-flies are too small and inconspicuous to make it worth while to try and catch them. The grubs when full grown make small cocoons about two inches below the surface of the soil, which may sometimes be found in large numbers close together. After an attack in the winter the soil under the bushes should be removed and burnt, or buried at least 6 inches deep. This if properly done would insure your bushes not being attacked again; but unfortunately the Saw-flies may come from your neighbour's garden, but if every one in a large district would agree to carry out this plan this pest might be almost "stamped out."—G. S. S.

A group of English grapes. (See page 164.)

extra fine from the medium sized fruit, and in the markets the former or the consignment will sell very much better accordingly. W.

RED-SPIDER ON VINES.

Of all the insect pests that trouble the Grape cultivator, none are so difficult to get rid of, or do so much damage to the present and future crops, as this insidious pest. The first indication of the presence of red-spider on the Vines occurs on the leaves nearest to the main stem on any part of the Vine; sometimes it is over the hot-water pipes, and at others at the extreme point of growth. In the former instance the cause is very often attributable to the persistent dryness of the atmosphere above the pipes, caused by overheating them, and a lack of moisture in that particular spot, both on the surface-soil and about the hot-water pipes. A warm, dry air is a sure precursor of red-spider. When the Vines are attacked from the point of growth, the cause may very often be traced to the presence of already infested plants being placed in too close proximity to the Vines, such as Strawberries or French Beans, or indeed almost any other plant that is subject to attacks of this insect. A shelf situated in this part of the vinery is a favourite site for such subjects as those named, and one very often seized upon by these with but a limited space at command, but with much risk to the Vines themselves. Upon a close examination of the leaves the presence of the spider will not long remain in doubt, and if steps are not taken to promptly remove the pest, the difficulty will increase almost daily. Vines that

hand and with a few sharp puffs from the distributor cover the leaves with the sulphur. Should a little sulphur lodge on the berries a few sharp puffs of breath will dislodge that without injury to the berries. Of course, great care is necessary in handling the leaves among the bunches, but with care there is really no trouble in this. The Vines most generally affected with red-spider are Muscat of Alexandria, Madresfield Court, and Black Hamburg. S. P.

3669.—Stopping a Vine.—Do not wait until the Vine is in flower, but stop every shoot at two or three leaves beyond the bunch, and never allow more than two leaves to remain, as I find that the berries swell up and colour just as well as if the shoots are allowed to extend further. The lateral shoots must be pinched out as they form, so that the flow of sap is concentrated over the leaves and branches. When Vines are doing well several shoots will push out together from the main stem. Only one must be left, selecting that which bears the best bunch.—J. C. B.

3681.—A plague of caterpillars.—Three quorists ask about Gooseberry caterpillars. I may as well answer all three in one letter. Gooseberry and Currant-bushes are frequently stripped of their foliage by the caterpillars of the magpie moth (*Abraxas grossulariata*), and the grubs of the Gooseberry and Currant Sawfly (*Nematus grossularis*). The caterpillars of the magpie moth pass the winter in curled-up dead leaves, which are often attached to the tree by a silken strand of silk spun by the caterpillars. Under the short leaves fallen from the bushes,

3753.—Vinery.—The size of the house must be governed by the requirements from it in the matter of Grapes. The Vines should have a space of 3 feet between them. This will act as a guide as to the length of each vinery. As the ground runs east and west a lean-to vinery would obtain the most sun and be the most suitable form for the site. Span-roofed vineries are the most economically built, but they should run north and south, thus each side would obtain an equal share of sunlight. In the case of a lean-to vinery, if the position is not too much exposed to north and easterly winds what is known as a three-quarter span is a good form of house to erect. Additional light is obtained through the glass which forms part of the back. A house 27 feet long will accommodate eight early Vines or seven late ones, the latter require rather more space than the former on account of the growth being a trifle stronger. The width should not be less than 16 feet; height from floor-line to ridge, 12 feet; height of front lights, 1 foot 6 inches; length of the back lights, 3 feet; and height of the back wall, 11 feet 6 inches. If a plain lean-to house is preferred the back wall should be 13 feet high; height of the front, 4 feet; width, 15 feet; the length according to requirement. The inside of the vinery should be so constructed that a border 3 feet deep can be made—2 feet 3 inches for soil, and 9 inches for drainage. The front wall should be built on arches to enable the roots to run into an outside border 10 feet wide. The Vines ought to be planted inside the house, 15 inches from the front wall. Provision should be made for heating the house efficiently. It is false economy to limit the supply of hot-water pipes; where there are too few they have to be made so very hot to maintain the necessary amount of heat that it is injurious at times to the tender foliage; besides, quite as much fuel is burnt in heating the fewer pipes. If the Grapes are required to be ripe in July six rows of 4-inch pipes are not too many in a house similar to that just described. Five rows of the same size would be ample for the lean-to vinery. For late Grapes one row of pipes less in each house will suffice.—S. P.

Span-roofed houses are the most common nowadays. Lean-tos are very well when there are garden walls already in existence to build against. If you look round your neighbourhood, including Worthing, you will pick up a lot of useful information before you begin to build. Have the houses as large as possible for Grapes. One wide house is better and cheaper than two narrow ones.—E. H.

Span-roofed houses, running north and south, is the form most suitable for vineries in such a case as yours; but as your ground is only

40 foot wide you are limited in the length. Supposing you make the houses 30 feet long, that will leave 10 feet for a roadway. A width of 18 feet gives a fairly long rafter, and at the same time provides ample internal space. By all means have the houses heated. Two rows of 4-inch pipes along both sides and one end will be sufficient piping to keep out frost.—J. C. C.

CROWDED PEACH SHOOTS.

In matters of Peach culture, as in most others connected with gardening, there can be no hard and fast rules laid down, but in a general way if the shoots are left or laid in during the winter, training at from 4 inches to 6 inches apart, they will be quite near enough, and in doing this, or rather before, in the pruning, an eye must be exercised to leave them that they may cover all space on the wall, and have no waste of room. Starting with a young tree, the way to manage when it is received from the nursery is to look over or examine the head, and if there be a centre shoot it should be taken out close down, using a keen-edged knife for the purpose. This throws the middle open, which in the case of all trees that are intended to be fan-trained is the thing to do, as the sides can then be filled easily, the growth being forced in that direction instead of upwards. Shoots may gradually be carried from the two upper branches and the wall covered in very quick time, or a space of 100 foot square in two years. I have done this repeatedly, and am never satisfied unless a tree grows to that extent, but then I never get back, which I regard as a foolish practice, as when carried out the tree operated on is at the end of the first year at about the same stage as when brought in, it having made as much growth as had been out away, and many gardeners then shorten again, thus wasting precious time and undoing what the tree had done. If one enquires the reason for this mutilation, he is told it is to make the plant break back; but who ever saw a healthy young Peach, Plum, Pear, Cherry, or what not that will not, or does not, start all its buds if planted properly and at the right season? It stands to reason that the more head a plant has and the greater the leafage, the more roots it forms, the more quickly it increases in stem and branch and becomes established. This, I think, is evident, and the less of a knife a young tree has the better, and instead of cutting I advise all shoots to be laid in full length and an equal number on each side. These, trained regularly at an equal distance apart, form the frame, and give a fair start. In the spring comes the disbudding, and then a little judgment is necessary to decide on which shoots to leave, but all should be situated on the top side of the branches and well placed at a

SUITABLE DISTANCE APART, and others rubbed out (unless needed for spurs), when those left will grow away and should be so trained that they form no elbow, which may easily be prevented by giving a tie near the base so as to keep that part somewhat close to the main stem, and more in line with it. The after-training consists in leading each shoot on in its proper course, and taking others from them on the upper side the year after, till the wall space or trellis is filled with the right number of branches. If these are of Pear, Plum, Cherry, or Apricot, of course they will have spurs, as instead of rubbing out or disbudging, as in the case of Peaches and Nectarines, the shoots should have been kept stopped by pinching during the summer, which then forms the spurs. We now come to the fully grown or fruiting trees, and now is the time to be at work at them, as directly Peaches or Nectarines are set, thinning or disbudging the shoots should commence at once, but be carried out piecemeal, a little one day and so on the next till the job is complete. If the pruning and laying-in have been as mentioned, all the shoots necessary to be saved will be one at the top and one at the base of each shoot, the latter, of course, on the upper side so as to be close with the wall or flat with a trellis. The only exception to this rule of disbudging Peaches and Nectarines is in cases where a young branch is extra long; then another shoot may be requisite midway, or if it should happen that there is a bare space, that must be provided for, and a shoot or shoots left to fill in. As soon as these get 2 inches or 3 inches long, they should have a tie run round them and the branch they emanate from, and a string and knot them

nearer together; otherwise there will be what is termed a shoulder or ugly bend where they start. The tie obviates this and makes the branches lie flat and run off as they should. With pyramide and hush trees grown in houses, the tying at the base is unnecessary, but the disbudging should be carried out in much the same manner as when trees are trained, and no more shoots are left than are absolutely requisite. Some adopt the double system of young shoots and spurs, and then stopping comes in. If one has a very light, roomy structure, the growing of hush trees has many advantages over those trained, as they are far more natural, the leafage is fully exposed, and there is not half the labour and trouble involved in managing and looking after the trees. I have a span-roofed house filled with Peaches on one side and Nectarines on the other that are as free as Willows and will give much more fruit than if they were on trellises. S.

3726. — **Caterpillars on Currant-bushes.**—Heliothrips powder, either applied dry or mixed with water and syringed on the bushes, will be effectual. Soap-and-a strong solution of soft soap and water with a dash of paraffin in will clear them off in a couple of dressings. Use the soap and water at the rate of 2 oz. to the gallon and a half of water, add a wineglassful of paraffin to the same quantity, and use it warm.—E. H.

— You will find an answer to this query in GARDENING, May 13, 1892, page 140.—C. T.

3778. — **Treatment of Vines and Pines.**

—Your Vines are evidently out of condition at the roots, or else they have been subjected to too much heat which caused the bunches to run out. Sixty-five degs. to 70 degs. by night is too much warmth for Vines that are in a weakly condition and which have not formed their bunches. The bunches would not, however, have run out and withered away if the roots were in a healthy state. You had better lift the roots and replant them in a new border early next October. Meanwhile, give the house plenty of air, and keep the foliage free from red-spider by damping down the floor three or four times a day, and syringing it well of an evening. Fruiting Pines should have a day temperature of 95 degs. by sun-heat, and 70 degs. by night, the bottom-heat should not be less than 80 degs. Up to the time the fruit begins to change colour put one ounce of guano in every gallon of water you give them. Damp the surface between the plants twice a day, and if the leaves are near the glass use a thin shade in very hot weather.—J. C. O.

3735. — **Treatment of Vines from cuttings.**

—Presuming that the cuttings were inserted singly in small pots, and that these are nearly filled with roots, a shift into pots 8 inches in diameter will be required; in these the full season's growth will be made, and the Vines in the early part of 1894 will be ready to plant in their permanent quarters. A compost of three parts sbrly loam to one of partly-decayed horse-manure, a sprinkle of bones (fine ground), and sufficient charcoal to keep the whole porous, will grow excellent Vines. Restrict the growth to one stem, pinching the lateral shoots in above the first leaf. In this way the whole energy of the plant is concentrated in the single cane, the bud at the base of each leaf is nurtured and rendered plump; in time these basal eyes will produce bunches of Grapes. When growth is being made freely abundance of water at the roots and overhead will be required. Stand the plants in a warm corner of the greenhouse, as near to the glass as possible, where abundance of light will be obtained.—S. P.

Early Strawberries.—It may interest the readers of GARDENING to know that on the 8th May I gathered two dozen ripe Black Prince Strawberries from a wall border, which I planted last September, where they have had no protection.—R. W. H., *Ringwood, Hants.*

The Parrot Tulips.—Amongst the strangest of flowers are the Parrot Tulips, which are in full bloom early in May. They are later than the ordinary Dutch kinds, and seem to be getting more popular in gardens. A few bulbs in a small garden are of much interest, but the full splendour of the flowers is revealed in the mass, where the bulbs are planted thickly to make a surface of colour. The Parrot, or Dragon Tulips, as they are sometimes called, get their popular name from the similarity of the segments to the beak of a Parrot. They are of

very quaint shape, and the colours are remarkably rich, crimson, gold, and curious mixtures, crude contrasts, and their bold, ungainly size adds to their curious aspect. In a small garden I saw a bed of them which had a brilliant appearance; and, although there are named kinds the mixtures are quite distinct and quaint enough.—C. T.

ENGLISH IRISES.

Few flowers in the early spring are so welcome, so beautiful, or so delightfully fragrant as the reticulated Iris and its varieties, and although it is with the greatest difficulty kept alive even, in some districts so strong has the love for this beauty grown, that people who cannot grow it out-of-doors manage to have a few pots for the conservatory, and for such a purpose it has few equals. The old idea of cultivating these bulbous Irises as we do Squills and Meadow Saffrons has long since exploded. They require frequent lifting, and the better they are stored and drier the greater will be the success. Our summers are too cold and wet to leave such bulbs in the ground, and covering over with glass frames is not nearly so effective as lifting. Another practice which tells against their successful culture is early planting; these bulbs should never be planted before late autumn or even mid-winter. In the first place, they have a better chance of being thoroughly dried, and in the second place, little or no leaf growth is made to be destroyed by the severe frosts in winter. They should be encouraged, however, to make root growth, and this will be greatly facilitated by a covering of leaves or loose Pine branches in hard, frosty weather. This applies more or less to all the bulbous species, and even in the case of the English and Spanish race of bulbous Irises I have seen many fine beds and groups destroyed by frosts, the result of too

EARLY PLANTING causes the foliage of the Spanish Iris to brown and wither at flowering time, and this may be to a great extent avoided by planting in the latter end of September or October instead of in August. Both the Spanish and English Irises are more largely grown in gardens than any of the other species, and the perfection reached by raisers of these new varieties in the marvellous colours and markings, and the curious blends and blotchings entitles them to a first place amongst hardy hulks. They are not only more easily grown, but they are less subject to disease than, for instance, the forms of *I. reticulata*, which simply refuse to grow at all in some localities, and although this disease may be somewhat retarded by lifting and careful storing, it is very difficult to eradicate, and in wet seasons carries the hulks off by the thousand. The English Irises, of which a fine group is illustrated on page 163, are more robust and withstand the rigours of an English winter and wet summer much better than the others. The name English Iris seems to have been applied to *I. xiphoides* in the very early days of hulk culture. It is a native of the Pyrenees, with a very limited distribution, and it appears that the hulks were introduced from there to Bristol, and then to Holland, where it was called English Iris. It is a most charming summer hulk; the intense blues, the pure whites and the various markings and blotching of the flowers are extremely effective in groups and never fail to attract attention. There is a curious form called Thunderbolt of a dusky dull colour, which seems to have been well known to Parkinson in the old days. It is said to be a hybrid between the English Iris and *I. filifolia*, but of this nothing very definite is known. It rarely seeds in cultivation, and is grown chiefly out of curiosity. *I. Xiphion* (the Spanish Iris), from Spain, Portugal, and Algiers, is one of the finest and most variable types of bulbous Irises. It includes all the colours of the rainbow, some of the varieties being very remarkable from the curious blendings of these peculiar shades. They may all be obtained readily of any hulk merchant for a few pence, and in a few years large groups may be had, so quickly are they increased from offsets. They may also be raised from seeds. K.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in

THE KITCHEN GARDEN.

CARROTS AND THEIR CULTURE.

CARROTS require a deep, light, warm soil, well trenched and previously well manured. Sowing must be effected in dry weather, for, should a shower happen soon after the seed is in the ground, the crop will, in most cases, be a failure if not sown again immediately. Drills ought to be preferred to broadcast sowing, there being no possibility with the latter of

Carrot "Long Red."

attending to the crop conveniently. The French Forcing and the Scarlet Horn Carrots are the best for forcing, but the first is to be preferred. Prepare mild hot-beds 2½ feet high in November or December, and 1½ feet or 2 feet in January or February; put on the frames, cover the bed with 5 inches or 6 inches of rich soil or mould, and, as soon as the whole is sufficiently heated, sow the seed broadcast, cover with half an inch of mould, smooth the surface, and cover the glass with mats until the seed comes up. Should the interior get dry give a slight watering, but be careful of damp. When the plants have four or five leaves thin them half an inch apart. Admit air as often as the temperature will allow of it, which will give strength to the seedlings. Take care the heat does not exceed 60 degs. during the day and 50 degs. at night, which may be easily regulated by tilting the glass. In the case of sharp frost covering with mats is preferable to artificial heat. Shading, if needed, must not be omitted. Sowing in November, if carried on by practical men, will produce fine young Carrots at the end of February, which will last through March and April. Subsequent sowings—in December for March to April, in January for April to May, and, lastly, in February for April to June—must be attended to as required by market gardeners; but in private gardens the first bed should be made in November and the second in January. These will afford an ample supply until new open-ground Carrots are fit for use. Where frames are not available prepare, at the beginning of February, in some warm corner, a bed of hot dung mixed with leaves, covered with 4 inches or 5 inches of mould; sow the seed and protect with mats supported with sticks or other apparatus. As soon as the seed comes up remove the covering every day as frequently as the weather will permit, and the crop will be ready from the end of April to that of May. Parisian market gardeners mix seeds of Radish and Lettuce with those of Carrots, the former being ready for use before the Carrots, which are then left to produce a second crop, a practice not advisable, not that of planting Cansflowers amongst forced Carrots,

OPEN-GROUND CULTURE.—For the first crop sow in February, on a warm, dry border, the Scarlet Horn Carrot, in 3-inch drills; cover the seed with half an inch of decomposed mould; when the young plants have formed a few leaves, clear off the weeds, and thin them to 1 inch or 2 inches apart, hoeing and watering as required. The crop should be ready by the end of May, and will last until the general crop comes in. In June sow the same kind of Carrot again where small roots are preferred. General crop: Intermediate Scarlet, Intermediate Stump-rooted, and Intermediate Nantes, are the three best varieties for general crops. Sow them from March to May (the later month for winter Carrots) in well-prepared soil, in 9-inch to 12-inch drills, half an inch deep. As the Carrots make their appearance, hoeing, weeding, watering, and thinning them to half an inch apart should be duly attended to. So soon as the plants attain the size of a lead pencil, thin them to 3 inches or 4 inches apart without hesitation. Thinning generally receives too little attention in every country; and the Carrots, crowded when young, are left to be taken up for use when they have attained sufficient size. In most cases, the ground gets dry and hard, and thus prevents the lifting of the roots, which are then left until the autumn, when only small, useless Carrots are the result. Autumn sowing: In August and September select a warm border. Sow French Forcing or Scarlet Horn Carrot, as for the early crop. The roots must remain in the ground the whole winter; but, if they are well protected and the bed is covered with an inch of mould, fine little Carrots will be ready from February until May. Field sowing: No roots succeed better and are more easily cultivated in the field than Carrots. Select a rich soil, deeply trenched, and previously well manured. A little addition of salt will produce excellent effects. Sow from March to May, in from 10-inch to 15-inch drills, keeping all the plants 4 inches or 5 inches asunder, according to the variety. Weeding and repeated hoeings will ensure an abundant crop; but be careful in choosing dry weather for such operations.

LATE PEAS.

IN May it is necessary to make arrangements for the supply of late Peas. As the term late may be somewhat misleading, I may state that I refer to those which are to succeed the general crop, and to give a supply till out down by severe weather. In some gardens, especially in wet, damp positions or on heavy clay, it is difficult to get late Peas, so the pods do not fill well, the haulm being attacked with mildew. In such places special preparation of the ground is necessary, and at no time of the year can this work better be taken in hand than in the early spring months. Mildew is equally troublesome on thin light soils, as, owing to the roots often suffering from drought in the months of August and September, a collapse takes place. I do not attach so much importance to the variety as to the preparation of the soil or trench. Though such kinds as No Plus Ultra are difficult to beat for the latest crop, there are others more useful on account of their taking up less room and not requiring such tall stakes. Of late years considerable attention has been paid to the raising of new Peas, and though we have not gained much as regards earliness, there is considerable improvement in the character of the early Peas, as there is more of the Marrow character in them than was the case years ago. This is a decided gain, as the small white-seeded varieties were soon over. Varieties with the Marrow blood in them are more lasting, yield better, and come in nearly as soon as the white-seeded varieties. The only difficulty is that they are not so suitable for heavy, wet land as the early white kinds, as

MARROW PEAS do not germinate so readily as round white ones, and when sown too soon in cold, wet soil they often decay. I have named the early varieties in this note on late Peas for several reasons, the most important being that they are often recommended for late sowing. I have tried them, but they possess less value than some of the later and dwarfier sorts. The first varieties are invaluable, and I can strongly recommend them for sowing in June or July for the late supply, as they take up little room and are more readily protected than taller kinds.

For sowing for a late crop, that is to give a supply through September and October, one of the best Peas lately introduced is Success. This I tried last season, and as the autumn was very wet, I was much pleased with the result, so I had good Peas till the end of October, and they suffered little from mildew. The advantage of growing a Pea 3 foot or 4 feet high is seen in the space occupied, the convenience of using shorter stakes, and the smaller amount of moisture required. I used a 3-foot Pea called Sturdy for some years for late cropping, and I do not think it can be beaten. It is not every one, however, who can give the time and space to grow such late Peas. When grown so late they do not give a large return; still, a good dish of Peas in a country house during the month of November is much appreciated.

IN THE CULTURE of late Peas, so I have previously stated, special care is needed, and here the gardener with plenty of manure has an advantage. As far as I have been able to judge the one thing needful for late Peas is plenty of good decayed manure to give the haulm the necessary support when a spell of dry weather sets in. In cold, wet positions the need of a liberal supply of manure is equally necessary, as often when tall Peas are grown and in rows close together, the tops in a wet season are scarcely ever dry, and the cool, moist weather causing an abundant haulm, the roots cannot supply the amount of nourishment required. The early crops do not suffer so badly, because the sun is less powerful and the earth not dried up so readily. In dry, light soils the value of manure is more necessary, so that at this season to get good results from late-sown Peas trenches similar to those for Celery should be employed. I advise that they should be wider than when a single row of Celery is planted. I like a 15-inch trench, as this allows of a good amount of manure. The manure should always be thoroughly decayed, and on light soils I have used cow-manure to advantage, as it is cool and retains the moisture. From 4 inches to 6 inches of manure is none too much. The

MANURE should be dug in, the Peas sown on the top of the soil, and some of the soil thrown

Carrot "Intermediate."

out used to cover the seed; this will reduce the depth of the trench. A deep trench is not wanted, only sufficient to retain the moisture. Tall Peas may be topped at 3 feet or 4 feet, so that tall stakes are not necessary. If possible, allow plenty of space when sowing between the rows, as the ground can be cropped with other vegetables, such as Cansflowers or rows of late Celery. This latter when allowed room does well, so the Peas give a slight shade when the Celery is first planted, and the space between the rows gets thoroughly cultivated by deep digging and manuring. The value of frequently

giving a good supply of moisture to late Peas is soon seen by the vigour of the haulm. This is required in quantity in August, and even later if September is hot and dry. Those who can flood the rows with a hose will find it the best system, and it is none too often to soak the trenches twice a week in dry seasons, it being a good plan where there is a plentiful supply of moisture to allow the water to run slowly, changing the position of the hose occasionally. It is of little benefit to apply large volumes of water at long intervals, as once a check by drought is given mildew soon attacks the Peas. In wet land less moisture is needed, but feeding is equally necessary for late crops. It is also a good plan to mulch the space outside the sticks and as close to the roots as possible with litter or manure, so as to retain the moisture in the soil. This is more necessary on gravelly soils; a mulch about three inches deep will save watering. This sowing is also necessary to allow a robust growth; also a good position on an open quarter not shaded by trees. The Peas should be earthed up and staked before the growth is far advanced, as growth is very rapid as soon as the roots reach the manure in the trenches.

G.

MUSHROOMS IN SUMMER.

During the best of summer Mushrooms are not needed as broilers, but for flavouring they are often in request. A close, muggy atmosphere, such as will be present in places where this esculent may be cultivated with success throughout the winter months, is not suitable for the production of summer crops, unless the holding is so constructed as to enable it to be kept as cool as circumstances will permit. The best holding I ever saw for the production of Mushrooms in summer was a thatched-roofed structure behind a north wall, and which had free ventilation. Not that an arid atmosphere was encouraged, for mats were hung in front of the windows and doorway. These and the thatched roof were drenched with water through a hose; consequently cool and genial surroundings were promoted. A very good position would be an open shed facing north, hanging mats over the front during the day and throwing open during the night. The roof being thatched, a cooler and more equable temperature can be maintained than could otherwise be secured if the roof was of slate. Often a very cool site may be secured at an angle of a north and east wall, and if partially overhung with trees, all the better.

A COOL CELLAR, if not too confined, is also suitable for a summer bed. During the winter these underground cellars are well adapted for Mushroom growing on account of the genial surroundings, the temperature also being considerably lower than in a structure above ground. Many people are led away with the idea that ridge-shaped beds formed in the open air are good for summer crops. This is a very erroneous opinion, for they become so hot and dry, that what Mushrooms are produced are of a very unhealthy description, and, in fact, would be discarded as useless. It is an old practice, but, nevertheless, a good one, where the roots of Rhubarb are surrounded with manure, to insert pieces of spawn in May, in which position the spawn commences to run and some useful Mushrooms are secured. Many gardeners no doubt could point to success with Mushrooms during the summer months through quite accidental means. I once paid a visit to a gardener during the month of July, and he showed me a fine bed of Mushrooms in his Mushroom house, which was a thatched structure behind a north wall. This bed was made up during the early part of the year for a spring supply, but the Mushrooms did not appear at the time expected. The bed was, however, left untouched, and a plentiful supply of good produce at the time stated was obtained. If coolness is one of the essential points in securing a summer supply, moisture is also requisite. It would pay even now to give partially-exhausted beds a thorough soaking of water impregnated with salt. Diluted manure water I have also used with success, this assisting in re-storing the material with ammonia, a very desirable element if Mushrooms are expected to thrive.

Insects are troublesome at all times, but never more so than during the summer months.

It must be remembered that these very cool sites, which are selected and also kept correspondingly moist, are very apt to harbour slugs, which quickly devour the young Mushrooms. Woodlice are the greatest enemy to contend against. The well-known bait of boiled Potato enclosed in a small flower-pot with hay is a good plan for capturing these, but it must be remembered that the Potato is only an alluremant, so the flower-pots must be examined daily where these marauders are known to be present in large numbers. The practice of laying two rotten or decaying boards together in their haunts and covering with hay will attract numbers, which can then easily be destroyed. The surface of these summer beds should be lightly mulched with sweet litter—not hay, this being too close. If this be

REGULARLY MONITORED, it will assist in keeping away the flies. The Mushrooms as they appear must be pulled whilst in quite a young state, for it will be noticed that it is when they become old through being left too long that they become maggoty. It is easy enough to advise Mushroom beds to be made up in cool sites behind north walls to produce a summer supply, but it requires unremitting attention if Mushrooms worthy the name are to be produced. When forming open-air beds behind a wall I would advise excavating the soil to a depth of a foot or more, thus conserving the moisture in the material. Instead of thickly covering these beds with litter, as sometimes advised, and which I could never see the policy of, except during the early spring months, I place a thatched framework over the whole bed at the distance of 6 inches from the surface. If necessary a mat should be hung over this to assist in causing extra shade during the day. The old practice of inserting pieces of spawn in Vegetable Marrow beds at midsummer often results in good Mushrooms being secured, this shade from the Marrow leaves being just what is wanted. Spawn may also be inserted in Cucumber beds, and by the time the Cucumbers are ever I have known the surface of the bed to be "alive" with Mushrooms. A.

3756.—**Rhubarb for show.**—The ground for 2 feet away from the stems should be covered with partly-decayed manure to render the roots cool and to prevent the moisture evaporating from the soil. Liquid manures should be applied to the roots freely—at least, once in ten days a good soaking should be given. If the sticks are crowded pull out the weak ones and support the strongest to prevent their breaking.—S. P.

3760.—**Treatment of Cucumbers.**—The soil is evidently too rich for the plants. They will, however, soon grow out of their over-luxuriance. Give them nothing but clear water at the roots, and not too much of this—sufficient to prevent the leaves flagging, or red-spider will attack them. Do not allow the shoots to become crowded; all the main leaves should have sufficient space to develop fully. All sheets that are not near the roof, and therefore cannot obtain light, should be cut off as they are useless. Pinch out the points of all shoots above the first leaf.—S. P.

Big vegetables.—One cannot help noticing at shows that half the object is to get the various things exhibited as large as possible if a prize is in view. A Rhubarb, for instance, with stalks of abnormal size and coarseness is praised when well-grown medium examples are passed over. This is especially the case about cottage exhibitions; but I should not care to eat many of these productions, grown merely for exhibition, not for the table, and kinds chosen that are known to be of poor quality. This is quite a false system, and unfortunately is boldly encouraged by men who would not like to have these overgrown vegetables on their own tables. Rhubarb, Cabbage, Celery, and many other things we could name are invariably shown of huge size, and in the interests of vegetable growing this should not be permitted. Whilst, of course, the big things get prizes, competitors will continue to aim at size rather than quality. There seems, however, some change in the right direction, and a reaction against this system setting in.—C. T.

Dicentre eximes.—Perhaps someone who is GARDENING will like to know that this plant is very useful for planting

most other things, except Ferns, will not grow. I have it on a border facing north-west, raised from the ground level about a foot, but so much shaded by trees that it very rarely gets even an occasional gleam of the sun. Yet, notwithstanding its bad surroundings, this fine hardy perennial not only flourishes but produces many of its stately pink flowers. It is only growing in a common garden soil. Its fern-like foliage, added to its beautiful flowers, render it one of our most valuable and pleasing hardy plants.—V. P. B.

Verieties of the German Iris.—There are so many forms of Iris germanica, which is now freely in bloom in gardens, that amateurs must be puzzled to know which are the best out of the long list of kinds in cultivation. The following are all of good colour, not dull, and uninteresting, as is the case of many of the kinds in gardens. Very beautiful, of course, is the common German Flag, which has bold flowers of rich and striking colour. Aphylla var. Swerti, the standards white with veins of lavender; aurea, conspicuous for its fine yellow colour, the flowers of fine form, and handsome aspect; Bridesmaid, the flowers lavender, the falls with a white margin; and Celeste, which is perhaps the most beautiful. The flowers are large, rich lavender in colour, with a very delicate fragrance, and blooms with great freedom, whilst there is an orange beard to set off the soft lavender shade. Fiorentina is early; it is a beautiful Iris, and has almost white flowers, very sweetly scented, a good mass of it possesses much beauty. Gazelle, lavender and white, and Mma. Cheveu are two good kinds; the latter is largely grown for the market, and has an abundance of well shaped flowers, white, margined with lavender. A very handsome Iris is I. pallida dalmatica, the standards lavender, and the falls with a tinge of purple. This is one of the finest of the Irises, and a noble kind to mass together. Queen of May is a lovely flower. The standards are rosy-lilac, and the falls are of this colour also, but with yellow veins; an Iris that should be in every collection. Victorino, white and purple, and Xenophon, lavender and white, may also be recommended.—C. T.

HOUSE & WINDOW GARDENING.

3761.—**A house conservatory.**—You may have a number of interesting things in the conservatory—Polargoniums of all kinds succeeding well, and in the winter the plan may be kept gay by a good selection of Zonal varieties. Izoetes, and such things as Chinese Primulas, Cinerarias, and Cyclamens may be grown if you have a warm pit, but otherwise their culture will be difficult. Camellias may be grown against the walls or in pots, also Azaleas, and you may have in the summer plenty of Tuberous Begonias, Ferns, also such plants as the white-flowered Astilbe japonica, Chrysanthemums in variety for November and December, Cytisus racemosus, Dracena indivisa, Fuchsias, Grovilea robusta (an elegant plant), Lachenalias (particularly L. Nelsoni, a vigorous hybrid with rich yellow flowers), Roebia falcata (a fine succulent, its flowers scarlet), Solanum capsicastrum, better known as Winter Cherry, and the Streptocarpus, which are easily raised from seed soon thinned and just covered with soil. Put them in a light, warm corner, and prick out when sufficiently large enough to handle. Pot on, and in a comparatively short time you will get sturdy plants; they are very free, and the flowers exhibit considerable range of colour from almost white to beautifully pencilled forms. For climbing plants you could have Habrothamnus elegans, Lycopodium alba, and rosea, Passiflora, and the beautiful blue-flowered Plumbago capensis.—C. T.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This Journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most useful for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892. Forty-two vols., price, cloth, 48s. 12s.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

BEDS OF FLOWERS.

In a short time now summer-flowering plants will be put out into the positions for which they are intended, and a few notes on some happy contrasts of colour may be useful to readers of GARDENING. Of course, the plants are ready, or if not in stock orders have been given for them, as it is important to get them out as soon as weather permits.

TUBEROUS BEGONIAS are now one of the most popular bedding plants for the garden, and they seem to have been in greater demand since the last few wet summers, when the "Geraniums" (Zonal Pelargoniums) have run to leaf, and failed to make the garden bright with flowers. The Tuberosus Begoniae are also to my mind more interesting because less formal. During the past few weeks many queries have appeared concerning plants for small beds, and the Tuberosus Begonia is one of the most useful. The plant has improved greatly in habit, this being compact and free, the flowers appearing just above the base of deep-green foliage. The colours are varied, ranging from white to the deepest crimson, strong, decided, and making a bright display, used either separately or in shades of one distinct tone. Begonias are so striking that they require to be used with caution, and proper regard for contrast of colour. A very pleasing plant to use with it is the variegated *Dactylis*, which has graceful leafage, well coloured, and it grows freely in ordinary soil. The edging may be of Tufted *Pansies*, which are very charming bedding plants when used either by themselves or as groundwork to other subjects. I am now writing only for small gardens, as in larger places the arrangements of the beds are elaborate, although the same class of plants are employed. I much like a bed of only one variety of Tuberosus Begonias, or one leading colour—but this is, of course, a matter of taste. The time to put out Begonias is in the month when there is no fear of injury from frost. The soil should be partly light and plenty of water is necessary if the position is overdry, as Tuberosus Begoniae appreciate moisture and moderate shade. The

DAHLIA is another flower that is now used largely in gardens, and a good bed of either single, Pompon, show, the true Cactus, or the decorative makes a fine feature, as the plants are in no way formal. The Pompons comprise the best group, and if the reader is about to purchase, the best collection would be of about half-a-dozen kinds, if the garden is small, of course, and confined to White Aster, which has flowers of the purest white, and they are useful for cutting. *Comtoise Von Sternberg*, the flowers very pale creamy colour, the edge of the petals delicate yellow, a neat and attractive flower; *Fairy Tales*, soft primrose, Gem, rich scarlet, well named, Northern Light, bright red, and Prof. Bergeot, magenta-crimson, very fine. These I like greatly, as they are very distinct, and not too large. A very fine bedding Dahlia is *Kissing Sun*. It is very compact in growth, and the flowers are of a brilliant scarlet colour, perfectly double, like the heat of the show blooms, and a good bed may be composed of the Tom Thumb Dahlias, which signify varieties of very dwarf habit, rising only from 1 foot to 18 inches in height. The plants may be got for about one shilling each, and this new section of Liliptian Dahlias is likely to become much grown in the future. *Liliput* (pale carolite colour, shaded with orange), *Miniature* (yellow), *Bantam* (deep red), and *Hoopla* (maroon), are a few of the best. It is better to confine Dahlias in small gardens to the Pompons, singles, and Cactus types. Of the latter very good are *Amphion*, which may be described as chrome yellow, touched with cherry colour, the old *Juarez* (not very free, unfortunately, but bright in colour and of good shape), *H. Cannell* (rich maroon, shot with a crimson tone, quite velvety in character), *Charming Bride* (white, the petals tipped with rose), *Mrs. Hawkins* (the flowers yellow, the petals at the tips of a paler colour), *Panthea* (of a distinct salmon-scarlet, very bright and effective), and Professor Baldwin (which is of a brilliant orange-scarlet colour). I do not care for the decorative class; they are too coarse, except *Henry Patrick*, which is very free, and bears large white flowers of much beauty.

THE *FUCHSIA* is rapidly becoming a popular

garden flower. It is, however, only of quite recent years that the plant has again become sought after for bedding, as for a long time it was never seen except in the greenhouse. But it must not be overlooked that the *Fuchsia* is a fine garden plant, and in the London parks much use is made of it in the various arrangements. The great point to get a good show of flowers in the open is to let the plants make as much of their growth as possible in the open, so that it becomes thoroughly well hardened, and a greater abundance of bloom is as a result produced. Soft, seepy grown plants, taken straight from the warm-house to the open ground, frequently out a sorry figure, as might be expected. In the autumn when they have finished blooming they may be taken up and put away in some dry place for the winter. Such varieties as the *Earl of Beaconsfield*, its flowers tubular, and quite of an orange tint, and the old *Tower of London* are very handsome in the garden, but any of the good strong growing varieties will succeed well under these conditions. The great point is to get the growth well hardened before the plants are put out. The

HERRAZON'S LOBELIAS I see with pleasure are now grown largely in gardens, and the chief kind is *L. fulgens*, which is best represented by such beautiful varieties as *Queen Victoria* and *Firefly*. These may be planted out now, and good strong plants will bloom well during the summer, sending up strong spikes of intense crimson flowers, made still richer by contrast to the deep chocolate leafage. A small bed of either variety, edged with *Ageratum*, makes a fine display, the two colours going well together. It is the usual practice to take up the *Lobelia*s in the autumn and plant them out in a cold frame in ordinary soil for protection during the winter months, as they are a little tender, and it is worth while giving this attention to them. Few flowers in their season are richer in colour or make a more pleasing picture—intense crimson against chocolate, a superb contrast of colour. If one cannot devote a bed to them, get a good clump on the border to make a rich effect. During very dry weather keep the soil moderately moist. The

NIGHT SCENTED TOBACCO (*Nicotiana glauca*) is a very beautiful plant for the garden. The leafage is bold and of good colour, and the flowers are carried loosely on slender stems, the colour being creamy-white; but they open fully only in the evening, when they exhale a very sweet fragrance. They gain in effect by being used in contrast to deep-green leafage, and will keep up a display throughout the summer. It is very easy to raise the plants from seed, and notes have appeared before in GARDENING advising this course; but established examples can be purchased, and it is worth while to get a few for the distinct effect they produce in the garden. There are a few of the better plants for making a small garden gay in the summer and autumn months, as they will, if strong when put out, commence soon to bloom, and not cease until frosts cut short their career, when they may be taken up and kept over for another year. All the varieties mentioned are good, and the only thing is not to delay sending in orders if this has not been already done. The quicker the plants are in the garden—when, of course, it is safe to put them out—the better, and the season of summer flowers is extended. C. T.

BEES.

SEASONABLE NOTES.

THE Bees have had a splendid time among the fruit-blossoms, and swarming is likely to take place very early this season. If sections and supers be supplied to strong hives in good time much surplus honey may be obtained before swarming takes place. The chief indications of swarming are the appearance of drones, crowding of the Bees at the entrance to the hive, and general restlessness. The old queen leaves with the first swarm, while the young queen which is to take her place in the hive is yet in embryo. Preparations are made for swarming about a week before it takes place by the Bees beginning to raise young queens. When the queen-cells are sealed the swarm prepare to leave the hive, as the young queens arrive at maturity in from twelve to seventeen days from the egg.

When actually swarming the Bees pour out of the hive in a constant stream in a great state of excitement. The swarm usually clusters upon a bush or tree near the apiary, where it remains for a short time, but if not soon hived the Bees again take wing in search of a permanent habitation; no time should be lost in getting them into a hive as soon as the cluster is formed. Diapatch in hiving swarms is important on account of the Bees becoming more irritable and difficult to handle the longer they are left unhived. The time of swarming varies a good deal, so much depending upon locality, the state of the weather, and autumn management. Hives well filled with Bees in autumn are always in a far more forward state in spring than those that receive no attention in the way of uniting, stimulative feeding, and so forth. It is not the heaviest hives that contain the most Bees. Hives that have but little honey in them in spring afford plenty of room for hatching brood, consequently the population then rapidly increases.

PUTTING SWARMS INTO FRAME HIVES.—The bar-frame hive that a swarm is to occupy should have the frames filled with clean, empty combs if possible, the queen being thereby enabled to commence laying at once, and much valuable time, which would otherwise be occupied in comb-building, is saved. When empty combs cannot be provided, comb foundation should be fixed in the frames, either in sheets or in strips 2 inches deep. The swarm having been shaken into a hiving-skep, and the skep left on the ground for a short time to enable the Bees to cluster—a stone being placed under the edge of the skep to enable the stragglers to enter—may then be carried to the hive the Bees are to occupy, and the Bees at once shaken out on to the top of the frames. A light quilt being placed over the Bees, they will quickly run down amongst the frames and form a cluster, or a cloth or newspaper may be spread in front of the bar-frame hive, bringing one end over the edge of the alighting-board, and raising up the front of the hive a little to allow free ingress, and the Bees thrown from the skep on to the sheet, they will quickly run into the hive. The stock from which the swarm issued should be removed to another part of the apiary and the hive containing the swarm put in its place. The day after hiving the swarm the frames should be reduced in number to the size of the cluster of Bees and the hive contracted by means of division-boards. Wet or cold days immediately after hiving greatly check the progress of new swarms, it is therefore important to feed daily during weather unfavourable to honey gathering.

MANAGEMENT OF SWARMS.—Should it happen that a swarm issues from a hive after having commenced work in the supers, the most advisable thing to do is to remove the section-cases from the hive, and also all brood frames but two, and place them in an empty hive, which close up with division-boards, and remove to a new position. To the two frames of brood left in the old hive add sufficient frames of foundation to fill up the hive. Place queen excluder upon frames and return the section-cases, wedging up the hive a little in front. Having hived the swarm, shake it from the hiving-skep down in front of the parent hive, watching to see the queen enter, when all will quickly follow. The portion of the colony removed to a new position will raise a queen and form a separate stock. All hives and necessary appliances should be had in readiness that no hive may be lost when a swarm leaves a hive. Swarms sometimes cluster in very awkward positions for hiving. In some cases the only way in which to get a swarm into the hiving-skep is by placing it over, and gently driving the Bees up by means of a little smoke, or leaving them to draw up at will; care must, however, be taken to fix the skep securely or results may be serious. Through lack of this precaution it once happened to the writer to be placed in the somewhat alarming position of finding himself enveloped in a cloud of very angry Bees when mounting a ladder to secure a swarm that had drawn into a box that had been placed over it high up in a tree; unfortunately the said box had not been well secured, and the shaking of the ladder on being mounted dislodged it. The result may be more easily imagined than described.

U. S. G., Park Lane.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Proprietor. The name and address of the sender are required in addition to an designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issues immediately following the receipt of their communications.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, or, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3308.—Roses under trees.—Will any sort of Root do well in large trees, when the soil is good?—DORSET.

3309.—Cutting Asparagus.—Should all the small young growth of Asparagus be cut off the bed, or left to grow up?—M. F.

3310.—Roses with Ivy.—I have a high wall, facing east, covered with Ivy. Will any sort of Roses succeed grown with the Ivy?—DORSET.

3311.—Rose Cloth of Gold.—Does Cloth of Gold Rose succeed as a wall plant? I wish to get one, but have no room on a south wall?—DORSET.

3312.—Manetti Stock for Roses.—I should like to bud some Roses on Manetti for pot purposes. Will anyone kindly tell me what Manetti is, and where I can get it?—HOWARD.

3313.—Dwarf Roses.—What should be much obliged if someone would give me a list of some good kinds of Roses, to grow as dwarf planted near walls facing north, south, east, and west respectively?—DORSET.

3314.—Fruits of Obimonanthus fragrans.—I have several fruits of Obimonanthus fragrans or Obimonanthus procer ripening against the wall of my house. Is not this unusual?—B. C. G.

3315.—Treatment of Deutzias and Libonias.—I should like to know how to treat now Deutzias and Libonias, which have flowered most beautifully for the last six weeks? When or how to pot?—SCOTT.

3316.—Thuja Lobbi.—Would anyone kindly say what would be the probable cost of good plants of Thuja Lobbi, and if autumn would be a good time to plant, and is it particular as to position?—BOONBOR.

3317.—Wallflowers, &c., from seed.—I wish to give my own seed from Wallflowers, Pansies, Sweet Williams, &c. Is it necessary to fertilise them artificially? If so, what is the method of procedure?—AMATEUR.

3318.—Phlox Drummondii.—I am thinking of planting out a large bed on the lawn with Phlox Drummondii. Would it be best to peg it down or let it grow upright, and would it require an edging?—BIRMINGHAM.

3319.—Ants and greenfly on Roses.—Black ants nest my Rose-trees. Do they attack the greenfly, or do they do much damage on their own account? I have noticed them eating their way into a Rose-bud. Is there any remedy?—DORSET.

3320.—Tropeolum speciosum and Tussilago fragrans.—I shall be glad to have some information as to the best methods of growing Tropeolum speciosum and Tussilago fragrans? Are they both quite hardy enough to stand the winter in Surrey?—H. E.

3321.—Roses for out-flowers.—I find my Tea Roses grown in the open bed very soon after they are potted. I usually cut them at about 10 a.m. Has the time of picking anything to do with the matter? Will anyone kindly suggest a remedy?—DORSET.

3322.—Treatment of a Pear-tree.—Will anyone kindly give me information how to treat a Pear-tree which has not blossomed very freely this year? The tree is now making a lot of young wood—a great deal too much, I think. It is covered all over with shoots 12 inches long.—PEAR.

3323.—Ferns and Palms for a conservatory.—Will someone kindly advise me as to the names of some Ferns suitable for a small house to conservatory facing the east, and which can only be shaded to a small extent? I shall also be glad of the names of some suitable Palms for this situation?—T. E. G.

3324.—Stopping Melons.—Is it advisable to stop laterals of Melons immediately after fertilising, or allow the shoot to run on till the fruit is set? There has been some difference of opinion expressed on the matter lately. It is an interesting one, and I may say something further about it again.—BIRMINGHAM.

3325.—Maréchal Niel Rose.—I have a Maréchal Niel Rose growing in a pot in a large window; I have had it three years, and this year it has blossomed profusely. I wish to know what ought to be done to it when the bloom has gone? Should it be cut back or let remain set, and watered freely or sparingly?—LUCK.

3326.—Barren Strawberries.—I have a bed of Strawberries, all of which, with the exception of two roots, have this season turned out barren. The bed has been in the same place for several years, the plants being changed every three years, and has hitherto been very productive. The roots were planted about 3 feet apart, and I have always cleaned and well-manured in autumn. I should be much obliged for an explanation of this year's failure.—H. O.

3327.—Seedling Violets.—Will anyone kindly inform me if I could transplant a lot of seedling Violets now to a vacant piece of ground? The plants have come up in the borders in thousands, and I thought that they might be transplanted now. Also when would they bloom, and how should I prepare the soil?—ANXIOUS.

3328.—A weedy garden.—My garden is infested with a weed, Mare's-tail, which is spreading over it, and in places forming quite a network, and is choking up my Asparagus beds. I have had it dug deeper, but this only seems to increase it. The soil is very wet. What can I do to get rid of this terrible plague?—CHINA.

3329.—French Cannas.—Will "C. T." oblige me with the height of these Cannas? In the catalogue of a Paris firm they are represented as being about 1 metre in height—that is, over 3 feet. I consider that tall for pot culture. Please tell me if they will flower another season, and what winter treatment is necessary?—L. E.

3330.—Climbing Roses for a north wall.—I should be glad to know the names of about four good climbing Roses suitable for a north wall, which gets but little sun, but which is sheltered from the wind. Also a similar number of climbing Roses that would do well on a wall facing west, shaded by a high wall about 20 yards off?—DORSET.

3331.—An allotment garden.—I have an allotment garden in the West Riding of Yorkshire, where I am seriously annoyed by a neighbour's pigeons destroying and carrying away Peas as soon as they are sown; in some instances nearly whole rows have been lost. Can I destroy them in any way, or can I get legal compensation for the damage done?—SURREY.

3332.—A lean-to greenhouse.—I have built a lean-to greenhouse at my back-door. It is placed between two other kitchens, and the aspect is north, and it gets very little sun, it being 4 p.m. before the sun reaches it. I intend to plant a few Tomatoes in it. Would they grow? If so, will someone kindly give me a treatment of same, as it is my first attempt?—BIRMINGHAM.

3333.—Vines bleeding.—I cannot stop this, although I have done all I know. I have pruned them, used Thomas's Syzygia, and washed the wounds. There are four canes of Black Alicante and three Lady Downes. I pruned them the third week in January, and they have been bleeding ever since. I should be glad if anyone will give me some information how to stop this?—S. L.

3334.—Japanese Climbing Cucumber.—I have raised from seed a few plants of the new Japanese Cucumber, which, I am told, is very hardy, and can be grown like Borelet Runners. I should be glad to have some hints as to their cultivation, and to know if the fruit is of good quality. Is this plant of the same species as the ordinary Cucumber? Would any readers give their experience?—MIRADO.

3335.—Grapes, &c., for very early forcing.—Will someone kindly tell me what are the best sorts of Grapes to have for very early forcing in a viney 20 feet long against a south wall? Also what kind of vegetables can I force with Grapes? Will French Beans, Lettuces, and Cucumbers do, also Spinach? And how can I get a consignment of the Bristol and London markets to sell them?—COARWALL.

3336.—Strawberries and Clover.—Some three years ago I dug a quantity of young Clover roots in, and planted Strawberries on the top of them. I have noticed each year that the plants look much better there than on the land that surrounds it, which was treated the same and sowed at the same time. Is it from the decayed Clover roots, and if so, what do they impart to the soil? The land is light, with a sandy subsoil.—W. W.

3337.—Unhealthy Orange-trees, &c.—Will someone kindly tell me what is the matter with my Orange-trees? All the old leaves are falling off, and the tholld fresh ones as well. They are covered with blossoms, but hardly a leaf on them. The same with a Lemon-tree, and the blossoms, of course, cannot set. Not very long ago they were in most beautiful foliage, and the year before last one tree alone had upwards of a hundred Oranges on it, which made the most delicious marmalade.—C. A. M.

3338.—Early Chrysanthemums.—Will someone kindly inform me of the earliest flowering of the following Chrysanthemums, as I have very limited space for late flowering ones. These were sent me by a friend, but he gave me no idea when they bloomed. Contesse de Beaugard, Ferdinand Feral, Stanstead Surprise, Thunberg, Mona, J. M. Pigmy, Purton, Acquisdon, Omb of Gold, The Three Christinas, Jardin des Plantes, Jeanne d'Arc, Lord Alouster, Lord Wolsey, Violet Tomlin, Novelty, Lady Churchill, and Etolle de Lyon, and which of them are most suited for the cutting down system?—ASXWICH.

3339.—Strawberries for market.—I grow Strawberries for market purposes. There is a disease among them that kills them in patches every year, and they die right away at the top. If I plant every such good plants again on the same ground they go just the same, and my opinion is that there is something deficient in the land which they require to support them. I have seen several acres like it this year. Will anyone tell me the cause, or suggest a remedy? Finding it very difficult to get sufficient stable manure for my Strawberries, will someone please tell me what kind of artificial manure is most suitable for them, when, and how to apply it? They are Paxton's I grow.—W. W.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3340.—Rhubarb seedling (A.).—Cut off the stems before the flower.

3341.—Hog's Fennel (A.).—Is Miller's "English Names of Plants" Hog's Fennel is said to be Peucedanum officinale.

3342.—Glaire Rose drooping (Glaire).—You have suggested the plant in some way, and we don't think anybody could tell you the reason why it drooped, but the plant, and know what treatment you have been giving it.

3343.—Liquid-manure (H. B.).—Cow-manure can be used in a fresh state to form liquid-manure. It should be well diluted.

3344.—Tropeolum speciosum (B.).—This Tropeolum enjoys a deep, moist, and rather rich soil, and flourishes best in cool, moist places.

3345.—Wild Grasses (Miss Wilkins).—You should get Parnell's "Grasses of Britain." It is the best work I know; published by Blackwood and Sons.—J. J.

3346.—Shading for conservatory (B. J.).—Try a fine lime-wash, with a slight mixture of oil; material for the purpose can also be procured from nurserymen.

3347.—Hardy Water Lilies (J. B.).—Among Water Lilies nothing is better than the common English one, Nymphaea alba, and the common English yellow one, Nymphaea lutea.

3348.—Deutzia gracilis (L.).—This is a common shrub, cheap in every nursery, and it is scarcely worth your while to increase it. Plant it in the open air, as it is perfectly hardy.

3349.—Specimens of Polyanthus (P. J.).—The flowers of Polyanthus are much crushed in transit. They are not quite so good as they ought to be, or you have not sent us your best specimens.

3350.—Increasing Camellias (F. M.).—Camellias are now grown so cheaply and abundantly by various nurserymen that it is a waste of time and energy to try to increase them yourself.

3351.—Increasing Nicotiana affinis.—This plant is easily raised from seed, which is sown by many houses. (Questions relating to different plants must be sent on separate pieces of paper.)

3352.—"Geranium" flowers not opening (Surrey).—We cannot account for the flowers not opening. We think there must be some error in the treatment. Please give particulars?

3353.—The "crown" of a Dahlia? (G. S. B.).—By the term "crown" of a Dahlia we mean the collar, or part where the tubers join together, and when sowing the young buds of the current year's growth.

3354.—White Silene pendula compacta (C. C.).—A white variety under the name of S. pendula compacta alba, is quoted in several catalogues of well-known houses, and it is not dearer than the type.

3355.—Nicotiana affinis (F. A.).—This plant is a perennial, but is easily raised as an annual, and hence may often be described as such; just as the Castor-oil plant is treated as an annual here, it being in tropical countries a low tree.

3356.—Orobide for a warm house (Idle).—Well, I do not admire your sobriety, for with that character you will be no use for Orobide growing; and in order to set you going straight let us know what heat you mean to maintain?—M. B.

3357.—Definition of an amateur gardener (T. B.).—In the ordinary sense of the term an amateur is one who does not keep a skilled gardener. An individual who employed a man one or two days a week only would be called an amateur.

3358.—Plants for border of pond (J. U.).—We shall very soon publish an article on aquatic plants, in which you will find all the information you want. However, you must not expect water plants to do much good if you have many water-fowl.

3359.—Hyacinths after flowering (M. H.).—They might not be disturbed until the roots have decayed, then plant them out where you want them to remain. If the portions you refer to are decayed outting them off will do no harm.

3360.—Epidendrum ornabarum (C. Judd).—This is the name of the flower you send. I think I told you some time back there were no Dendrobies in South America—that is, unless they had been taken there by some one, and thus become naturalised.—M. B.

3361.—Cypripedium Obambralinum (Cypripedium).—You will find this plant easy to grow instead of difficult, and it does well with the others from the warmest regions. You will find the question as to C. Godfrey answered in page 160.—M. B.

3362.—Sweet-scented climber for a greenhouse (T. M. T.).—Maedevilla aurovirens, Rhynchospermum janicoides, Hellebore, Jasminum grandiflorum, and Stenactis latifolia are all suitable. We fear there is no yellow sweet-scented Jasmine for the purpose.

3363.—Cherry-tree not fruiting (W. V.).—We think you should not get despair of a fruit crop; there is no perceptible difference in the swelling of the germ for a few weeks, but should you get no fruit this year you must conclude that you have a bad setting variety.

3364.—Wireworms in a garden (R. S.).—You must make use of traps. Place slices of Carrots or Potatoes on the ends of pointed sticks, bury them 3 inches in the ground, examine them daily, and destroy the worms attached to them. The sticks serve to show where to find the bait.

3365.—Wintering Scarlet Lobelia (F. R.).—In light soils and mild districts we have known this plant to live out during the winter. Where it will not do so, the best way is to take up the roots in autumn, and keep them in boxes under a greenhouse stage or bench; put them out in late spring.

3366.—Transferring Rose from bottles to pots (B. A.).—Before the roots have got too long you should move them into little pots in the most careful and gentle way, and grow them in a nice cool frame until they have got on a bit. Then, in summer, expose them altogether until they make sturdy little plants.

3367.—Dendrobium Wardianum (C. Judd).—Yes, there are one or two varieties of this species. The plant that comes from Birmah is the stoutest built. The original plant comes from Amoy, and is a slender bulbous plant. It is very rare in cultivation at the present time. The others were imported from Birmah by the late Messrs. Low, of Clapton, and are known by the name of Wardianum, and the others are known by the name of Wardianum, and the others are known by the name of Wardianum, and the others are known by the name of Wardianum.

GARDEN AND PLANT PHOTOGRAPHS.

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded. The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; cut flowers, prettily arranged; pretty cottage gardens; our best fruits on the branch or branches, not in dishes; standard vegetables; good flower-gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS.—A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS.—First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or bush fruits, to be shown on the branches, not in dishes. No prize will be awarded to photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES.—A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in June, 1893.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoses, rollers, and other implements, iron railings, wires, or iron supports of any kind, also labels, especially those made of zinc (which should be removed when the photograph is being taken), and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted simply, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the sources whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 57, Southampton-street, Covent-garden, London, W.C., and marked "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

EVERYONE WHO HAS A GARDEN, GREENHOUSE OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WYTH, F.R.A.S., F.C.S. Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. ROSES.

PACKING ROSE BLOOMS.

For the past four years I have sent by railway a distance of 250 miles the produce of two houses that are principally devoted to the growth of Roses. My system of packing the blooms to travel this distance has been so simple that I venture to think a short account of it may be useful. The only two Roses I grow in quantity are *Marechal Niel* and *Niphetos*, both of which are forced early, so as to get the blooms to market before they become plentiful. I cut over four hundred blooms of *Marechal Niel* in the month of March. There is more judgment required in selecting Rose-blooms for cutting early in the season than is the case later. In the summer it is not unusual to find a half-open flower out in the evening fully expanded by the middle of the following day; but such a thing does not occur in the month of March. When placed in a lower temperature, blooms of *Marechal Niel* when cut in a half-open state are more likely to contract than expand. As a matter of fact, there is difficulty in getting the flowers to open sufficiently without giving more heat than is desirable for the later blooms. Nothing less than 10 degs. will get the blooms in a suitable condition. They will not expand even with that amount of warmth, but will remain in a half-open state until they fall. It is fortunate for the grower that the public are willing to accept them in that condition. For packing I use boxes 15 inches long, 12 inches wide, and 3 inches deep. In the bottom of the box I place a thin layer of fine clean Moss or paper shavings; on this I place a sheet of damp newspaper, and on this a layer of Rose blooms. With each flower I take enough of the shoot to secure two leaves, which are carefully wrapped round the bloom and placed close to the one that preceded it. The secret of packing the flowers is to place them close together, so that they do not move in transit. If the flowers get moved from their bed they rub together, and the edges of the petals get disfigured. When one layer of bloom is placed in the box, another sheet of damp paper is laid evenly upon them, and then another layer of flowers is placed close together on the damp paper, as in the bottom. Two rows of blooms are quite as many as it is safe to send in one box. In every case a sheet of damp paper is placed next the flowers, and if there is any vacant space afterwards I fill it up with soft paper. When I have a quantity of blooms I tie two or more boxes together. In cold weather I take care to wrap each box separately in thick brown paper to exclude the air. Flowers sent so early in the year, and such a long distance, would be comparatively worthless if indifferently packed. C.

3813.—Dwarf Roses.—With so much space to devote to Roses you ought to make a wide choice, so as to include some of all the classes that are adapted to that form of growth. To go near the south wall the Tea-scented varie-

ties will do admirably. From this section you may choose *Anna Olivier*, *Camcens*, *Comtesse de Nadallac*, *Etoile de Lyon*, *Grace Darling*, *Hon. Edith Gifford*, *Innocent Pirola*, *Lady Mary FitzWilliams*, *Mme. Charles*, *Mme. Hoste*, *Mme. Lambert*, *Perle des Jardins*, *Princess of Wales*, *Safrano*, *The Bride*, and *Vicomtesse Folkestone*. These can be had in pots and planted at once. To plant near the east wall the choice is equally as large, and I think this aspect can be made as interesting as any, if not more so. All the following are perfectly hardy, and will live for some years without attention, and many of them are sweet-scented, and if allowed to grow their way will, in a few years, form low, spreading bushes capable of producing hundreds of flowers. Early Yellow Roses may be had from a group of Austrian Briers, which includes two varieties with single flowers and two with double ones. The Scotch Roses are also very interesting; the principal colour amongst these are yellow, white, pink, and crimson. The Cabbage Rose you will, of course, find room for, if it is only for its delightful fragrance. Then there are the striped Roses, such as *York* and *Lancaster*, *Village Maid*, and *Rosa Mundi*, all of which are highly attractive when in flower. Moss Roses will be indispensable in such a case as yours, and although there are so many beautiful and newer varieties, the common pink variety and the *White Provence* must not be excluded. The west aspect you may devote to such of the Hybrid Perpetuals as you may care to grow, and for the north I do not think you can do better than make a varied selection, choosing the hardiest from the different sections. The Bourbons would no doubt thrive in such a position, especially such hardy ones as *Acidalie*, *Sir J. Paxton*, *Queen of Bedders*, and *Souvenir de la Malmaison*. The following Hybrid forms are known to be very hardy: *Brennus*, *Charles Lawson*, *Coupe d'Hebe*, *Paul Verdier*, and *Paul Ricaut*.—J. C. C.

"Dorset" will find the following all suitable for walls: *Cheabunt Hybrid*, *Gloire de Dijon*, *Kaiserin Frederich*, and *Bouquet d'Or* for north walls. *Rève d'Or*, *Henriette de Beauvean*, *Mme. Bérard*, the *White* and *Yellow Banksians*, and *Marechal Niel* for north walls. *Gloire de Dijon*, *Reine Marie Henriette*, *Duchesse d'Auerstadt*, and *Mme. de Tartas* for east walls. *And Belle Lyonnaise*, *Marie Van Hontte*, *Tour Bertrand*, *Caroline Kuster*, *Ophir*, and *Fortane's Yellow* for west walls.—P. U.

3821.—Roses for cut-flowers.—Decidedly the best time to cut these, or almost any kind of flowers, and especially in such warm and dry weather as we have experienced lately, is the early morning, between 5 and 6 a.m., when they are fresh from the coolness and dews of the night. Always cut them in the bud state, as they will expand considerably after being placed in water. But in any case I do not think this class of Rose ever stands so well when grown in the open air as under glass.—B. C. R.

Yes; it is because "Dorset" gathers his petals too late in the day that causes them to droop and lose colour so quickly. The

earlier in the morning flowers are cut the better they keep. All market growers recognise this, and either cut late at night, inserting them in water at once, or else do the same for a short time very early in the morning and before despatch. If they are cut early the colour will not fade, nor will they droop nearly so quickly, especially if they are placed in water immediately.—P. U.

You are not alone in your trouble this season, as I have had several complaints of the same thing happening to other flowers besides Roses. The long drought and the excessively high temperature that has prevailed is the cause of the flowers fading so quickly. Everything has been brought on with such a rush, owing to the heat, that no kind of flowers appears to possess any staying powers this season. With a decline in the temperature and more moisture in the ground this sort of thing will right itself again. Meanwhile, cut your Roses by 5 a.m., and take a flower from a plant that is dry at the root.—J. C. C.

—Ten o'clock in the morning is rather late for cutting Roses if you want the flowers to last. Cut them about six, or even earlier, and catch the buds in the act of expanding.—E. H.

3819.—Ants and green fly on Roses.—I do not believe the ants eat the Roses in any way. What they are after is the "honey-dew," or sweet excrement from the green-fly. They may also be seen sometimes carrying off a large fly, and it has been said they actually keep them in captivity, and allow them to breed for food. But what can the adult fly live on in the ant's nest? When the fly has punctured a Rose-bud, and caused it to exude the sweet, yellow-coloured juice we sometimes notice, I can quite imagine an ant eating into and feeding upon this gummy substance. Get rid of the green-fly, and the ants will cease to trouble you.—P. U.

3808.—Roses under trees.—The number of plants that will do well under large trees is very limited, and Roses should not be included. The old-fashioned hardy summer-blooming Roses, together with the different varieties of *Provence*, *York* and *Lancaster*, and others of equal hardiness, will grow wherever the soil is good and they get a reasonable amount of light. But under trees better be satisfied with *Ivois*, *Porwinkles*, *Acubas*, *Hollies*, *bulbs*, and *Primroses*.—E. H.

I do not think any Rose will do well under strong-growing trees. Even if your soil is good the roots of the trees will be certain to appropriate the greater part of the nourishment. Strong-growing Roses, such as *Rève d'Or*, *Dundee Rambler*, &c., would have the best chance, but I cannot advise your planting any Roses in such an unfavourable situation.—P. U.

The hybrid Bourbon and *Provence* Roses (including the old Cabbage Rose), also the striped *Provence* or "York and Lancaster" varieties, the *Boursault* section, and the varieties of *R. rugosa* will be found to thrive in such a position better than any others, and in good soil will do well.—B. C. R.

3830.—Climbing Roses for a north wall.—If your wall does not exceed 10 feet in height you may select the following, which will give you a nice variety: *Sir Joseph Paxton* (rose), *Felicite Perpetuee* (white), *Climbing Victoria Verdier* (crimson), and *gracilia* (rosy-red). For the west wall my selection would be *William Allen Richardson*, *Rève d'Or*, *L'Ideale*,

and Waltham Climber No. 1. I do not think the shade of a high wall 20 yards distant will do the Roses any harm. I notice you have another inquiry about the Cloth of Gold Rose. Why not try it on the west wall in place of one of the others?—J. C. C.

— "Dorset" has already asked this query, and has been replied to under the heading of "Dwarf Roses," 3313. The same varieties will do in the position stated in either query.—P. U.

3312.—**Manetti stock for Roses.**—The Manetti is one of the most common and also the most useful stock for dwarf Hybrid Perpetual Roses. It is not suitable for the generality of the Teas and Noisettes, nor for a few of the Hybrid Perpetuals. Any nurseryman advertising Roses in this paper could supply you with a few stocks; but it is too late to plant for this season's budding. You must plant in February or March next, and bud during the following July or August.—P. U.

3310.—**Roses with Ivy.**—It quite depends on the management. If you keep the Ivy cut away so as to allow the Rose growth to have a fair portion of the wall space, the two plants do very well together. Three years ago I planted the gable end of a high building with Roses and Ivy, and the effect is very pleasing, but each plant has a separate space of about 2 feet. During the summer the young growth of the Ivy mingles with that of the Rose, but it is cut away early in this autumn so as to allow the growth of the Rose to get hardensd. For an east aspect Gloire de Dijon and the Red Gloire are the best Roses.—J. C. C.

— The Roses would not stand much chance against the Ivy, and there is not much reason for thus planting them together. Even the Clematis Jackmanii does not do very well when thus planted. You might plant a Rose—say, Gloire de Dijon—against the Ivy, but not for shoots to intermingle, and you would get the contrast in colour of the flowers and deep-green leafage. I have seen the "Gloire" thus placed, and the effect was very good of its flowers against the Ivy, a few of the flower-laden shoots hanging over the Ivy stems. The soil for the Rose must be of a good loamy character, fairly rich, and if the horder is dry give plenty of water during the summer months. The best month to plant Roses is November, and get a good specimen to grow away vigorously from the commencement.—C. T.

— No, I do not advise your planting Roses with Ivy, for the same reason as I have already given against planting them under trees. The Ivy is very rapacious, and would certainly not give your Roses a fair chance.—P. U.

— Gloire de Dijon is the best Rose to plant to grow along with Ivy. Encourage it to make long shoots every year by pruning rather hard back directly the first crop of flowers are over. The Ivy must be kept in close to the wall by removing all superfluous shoots from the face of the leaves of the Ivy.—S. P.

3325.—**Marchal Niel Rose.**—You are to be congratulated on your success with this Rose in a window, as not many succeed with it when grown in that way. You do not say what size pot the plant occupies. If it is in one anything less than 8 inches in diameter, I should say it wants a larger one, and the sooner it has it now the better. You had better not prune it until the end of November. Meantime give water liberally, only not to the extent of keeping the soil constantly wet, and if you can substitute guano-water, or some other stimulating liquid, for clear water, this growth would be stronger.—J. C. C.

— Cut your plant back after it has finished blooming. In fact, cut it back to a healthy break near the base. Mulch with a little good soil, and water freely, adding a little weak liquid-manure at each alternate watering after your plant has commenced to grow again freely.—P. U.

3311.—**Rose Cloth of Gold.**—Yes, this grand old Rose will do better as a dwarf on the seedling or cutting stock than in any other form. Give it a sheltered position and the support of a stout stake, and you will succeed almost as well as if on a south wall.—P. U.

3330.—**Tap water.**—I have never known any injurious effect to ensue from using water from the waterworks. Thousands of the fine plants brought into Covent Garden-market are grown in this way. In some market-gardens the plants—many of them of a tender nature—are almost daily sprinkled with water from the waterworks. I know of places where no other kind is used, and yet growth is all that can be desired.—J. C. B.

GARDEN WORK.

Conservatory.

Cottages of the young shoot *Alyxia oliviflora* (Sweet Verbena) will strike now in a warm, close place. This, though a popular plant on account of its fragrant foliage, does not possess much decorative value indoors. I prefer it against a warm wall in the open air. I once had it planted against the front wall of a forcing-house, where it made very luxuriant growth, which flowered profusely, and was much admired. If there is likely to be any scarcity in useful plants to fill up the conservatory during summer a few of the best things among bedding plants may be shifted on. *Conna*, *Bismarck*, "Geraniums," of various kinds, *Phlox Drummondii*, &c., when well grown come in useful for stopping a gap. But with good collections of *Tuberose* Begonias and some of the best single and double Zonals, with a few Lilies and single specimens of such things as *Plumbago* capensis, *Blue and White Kalosantes* in variety, and the large specimens which can be spared from the stove and the fernery, there will be no difficulty in keeping the house attractive. Wood-stem bushes of *Hydrangea* are very useful, and large masses of *Agapanthus umbellatus* are charming when in flower either for the conservatory or to stand out on the lawn. Trees in pots which have ceased to be effective may be placed outside now. If the pots are plunged they will not require so much water, and the plants will do better. The Pelargoniums of the old show and fancy types have not lasted to long this season in consequence of the hot weather. As the plants go out of bloom place them outside to complete the finishing, preparatory to cutting them down. Hard-wooded plants must have free ventilation night and day. In commencing night ventilation the opening moves should always be moderate, just a little air being left on along the top of the house, these openings to be gradually increased till the plants will bear all the ventilation possible night and day. The plants will revel in the cooler air at night, and when freely exposed to it there is less danger to its apprehended from mildew or insect pests. No specimen plant should be watered without its condition being first ascertained by a rap with the knuckle on the side of the pot. There is on other test so reliable. Hasty haphazard watering is accountable for the deaths of a good many plants. There is not likely to be any demand for artificial heat before the autumn, and if the time can be spared the furnaces, boiler, fires, stoves, &c., should be carefully cleared out. The water may be run out of the apparatus, and may be filled in again with fresh water, where it can be obtained. Climbers are growing freely, and the necessary attention to regulate the growth must be given. Young stock coming on for winter blooming must have their water attended to in the pits and frames. It will be better to discontinue syringing, unless the water is quite pure and free from lime. Forced Asclepias which have completed growth may be in cold frames where the ventilation is very free.

Stove.

Seedling Gloxinias and Hybrid Stephanotis may be binned as yearlings if well grown, but they must be pricked off as soon as large enough to handle, and must suffer no check from cold, frost, and moisture. When coming into bloom move to a cooler house. Both these classes of plants may be used in the conservatory in summer, and will prove an important addition to that house if grouped at the warm end where a thin shade can be used. Summer flowers in the stove are usually fairly plentiful. Grand effects are produced by the *Alamandras*, *Dipladenias*, *Bougainvilleas*, *Stephanotis*, and *Clerodendrons*. These are not much grown by indifferent cultivators. To do them well they require more heat than is available in the ordinary cool stove, and unless well managed they get smothered with brown scales and become a nuisance. *Hoya*, including *H. bella*, are charming summer-flowering stove-plants. The last-named is a beautiful basket-plant. It requires good fiery peat, that will not get close and sour. *Russelia Yuca* is a very useful summer-blooming plant; does well in good-sized baskets; style of growth very light and graceful. *Yuccas* are exceedingly useful in summer blooming. When well grown they are useful to the exhibitor, and with care the same specimens may be made available for several successive shows—in fact, these large specimens would hardly pay for their keep unless they could be kept in condition to be trotted out to several shows.

Pits and Frames.

To a large extent the bedding-plants are outside, and the pits and frames will be filled up as quickly as possible in some useful manner. Several pits may be required chiefly for bringing on young stock of *Poinsettias*, *Euphorbias*, *Justicias*, *Begonias*, and other winter-blooming stove-plants. *Huwardias*, again, will require room to grow on steadily. *Cinerarias*, *Cyclamenos*, and *Primulas* near the glass. These various plants can be filled with *Guano*, *Melons*, *Cavendishs*, and possibly *Tomatoes*. The larger frames should be used for *Tomatoes*.

Fern-house.

Ferns are amongst the easiest plants to cultivate. A thin shade when the sun shines, abundance of moisture in the atmosphere, and just ventilation enough to keep the atmosphere buoyant—under such conditions the plants grow freely, and the fronds will get hard enough to use for cutting for bouquets and vases. Spores can be sown any time. When fully developed fertile fronds can be obtained, it is a very easy matter to work up a collection of large specimens of the usual kinds grown. Start with healthy, vigorous plants, and shift on as fast as the roots work through the soil. A healthy plant will take two or three shifts in a season.

Orchard-house.

It will be a great drawback if the supply of soil water gives out, and the syringe or engine has to be laid on one side, in consequence. Hard water must be exposed before use. Free ventilation is very important, especially early in the morning, though I always find it advisable to shut at four

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than in here indicated with equally good results.

o'clock in the afternoon, and damp down or syringe, giving a little air on mild nights to cause circulation about 8 p.m. Do not crowd the pots; better take a tree or two outside to make room. Keep the young growth thin, but do not be in a hurry to stop the growth of Paschoe.

Mushrooms for summer.

Make the beds now on the north side of a wall or building. It is not unlikely that manure which has been much exposed may be too dry. I would in a season like the present rather have the manure fresh from the stable; only the very longest of the straw to be taken out, and about one fourth of good loamy soil added to the manure, the whole to be well blended, and the beds made up at once. The soil will absorb the ammonia, and prevent over-heating or spawing. As soon as the heat rises soil it once, as the beds are not likely to get too hot. Cover with long litter to keep the beds from drying too much, and in six or seven weeks there should be plenty of Mushrooms.

Window Gardening.

Get all window-boxes filled now. Do not have things too close and prim. Let the growth have liberty to flow over the fronts of the boxes, and if a few creepers are planted in the ends of the boxes to be trained round the window, the effect will be enhanced. Cobias scandens is a very rapid grower, and if well watered will thrive in a box. Large vases or pots filled with "Geraniums," *Veronica*, &c., and placed about the firecourt will be bright and pleasant furniture. Indoors a few well-grown plants will give more satisfaction than a larger number of untidy specimens. Place *Myrtles* outside to ripen growth. *Orangers* and *Oranges* may stand in a sheltered place in the open air end of the month.

Outdoor Garden.

Where the hardy annuals have come up well thin the smaller growing kinds to 4 inches, and the large, spreading things to 6 inches. Do it after a shower, or else give a good watering, and as soon as the water has settled into the land draw up the surplus plants. Annuals may be sown for late blooming. The chances are that when the change comes in the weather there will be a period of dampness, and the last time may be made up. The land has had a good roasting, and will be frequent about the grassy banks. Give liquid-manure to Rose, *Phloxes*, and other strong-rooting plants. *Illydiums* must be well nourished, or the fungus will probably appear on the foliage, and the effectiveness of the plants destroyed. Wash Roses frequently; if syringed frequently with clean water *Lycotis* will not give much trouble. But when syringing is neglected and green-fly makes its appearance, something stronger than water must be used. Water used frequently will keep plants nice, but will not kill insects when the plants are badly infested. Place stakes to *Caranations* and all other hardy plants of good time. Thin out shoots in *Phloxes* where too crowded. The early flowering hardy bulbs have had a good ripening this season. *Hyacinths*, early-flowering *Tulips*, and *Crocus* may be lifted if required to make room for bedding plants. Get on with the bedding out now. It is like to plant just before rain if possible, the ground works so slowly when the surface is dry. Large plants with frequent shoots, with a hardy heart, such as *Geraniums*, with the flowers picked out, are always effective. There are many ways of using *Blue Salvia* all more or less pretty and effective. I have the *Salvias* planted thickly, and the beds filled in with small plants of the *Golden-leaved Abutilon*. Among *Barlets* "Geraniums" for masses there is nothing superior to *West Brighton Gem*.

Fruit Garden.

Strawberries will bear a good deal of liquid support now. It is a good plan to take the runners for forcing from plants which are not allowed to bear fruit. Those who can grow *British Queen* well will never give it up, but *Joseph Paxton* is so reliable either as a factor or in beds in the open air that all of us ought to try it. Three plants of *Violettrose de Thury* planted out now, and well watered, will bear another crop in the autumn. It is best to use seedling plants, but not to the same extent. If not already done the covers may be taken from the Peach wall. The probabilities are they have not been used very lately, but they will not be required now. It is a mistake, I think, to leave more Peaches than are wanted for the crop after this date, and Apples are often permitted to carry their surplus fruit too long. *Melons* where well nourished have had a splendid time, and where the ventilation has been right the leaves are hard and robust, and in a condition to resist the attacks of red-spider. In setting *Melons*, wait till there are four or five young fruits about to expand their blossoms nearly on the same day, so that all can be fertilised nearly together. If one fruit gets a decided lead it frequently robs the others. The young fruits or plants in a hardy and robust condition generally set better than when the plants have been grown in rather light rich soil, and perhaps insufficiently ventilated. *Melons* in pots or tubs must be well nourished. I have seen good fruit on plants in large pots, the latter being either planted or surrounded with old turf mixed with a little soil and bone-meal, both of which are soluble stimulants for *Melons*. Peaches under glass which have finished stouing will bear a little more heat for two or three weeks, and also more liquid-manure. *Vine-borders* both inside and outside, if well drained, may require a good deal of water.

Vegetable Garden.

It will be difficult until there comes a change in the weather to keep up a succession of Peas. The early varieties are rushed on into bloom before they reached their full growth, and the later sowings will not germinate without moisture, and the moisture must be a constant quantity, and not by fits and starts. Inexperienced people always fall in watering. They never seem to realise the actual necessities of the case, and even men who have worked in gardens for years, and who ought to know better, will not grasp the situation aright. Watering is heavy work, and this fact may serve to account for any shortcoming. Tender plants such as *Tomatoes*, *Vegetable Marrows*, and *Ridge Cucumbers* which have been well hardened by exposure may be planted out. *Vegetable Marrows* are very tender, but it will be easy to cover them for a night or two by inserting a large flower-pot over them. Good lettuce cannot be grown now without

mulch and moisture. Transplanted Lettuces will soon bolt. It is best to sow to drils thickly, and thin out to from 8 inches to 12 inches. Lettuce seeds are cheap enough even if it is necessary to sacrifice a few young plants. Good Radishes can only be obtained now by sowing in a shady position, and keep the bed well watered from the time the seeds are sown. I have found it an advantage to make the position rich with old loam and potting-soil to fill the ground full of humus to insure quick growth. In a dry sandy spot salad plants will do no good now. In planting out Celery or anything else now shading will pay. Branches out from trees, and either laid over the plants or thrust in the ground will be useful.

E. HOBAY.

Work in the Town Garden.

Should the weather continue as warm and bright as it still remains while I pen these lines, well-hardened bedding plants may be safely put out in fairly sheltered gardens at any time. It is best to begin with the hardier descriptions, such as the little Golden Feather *Pyrethrum* (really a hardy plant), *Verbena*, *Lobelia*, *Petunia* (these, too, are exceedingly hardy, if grown "cool" throughout), sturdy "Geraniums," &c., leaving the more tender *Begonias*, *Heliotropes*, *Dahlias*, &c., until June is well in; and *Coleus*, *Alternanthera*, &c., until late. Shrubby *Calceolarias* ought to have been planted weeks ago, and be now growing freely. The watering is the principal difficulty just now, and newly-planted stuff must be kept moist at least until the plants have rooted out, and become established, but if a mulch of Cocoa-nut-firm, spent hops, or the like, is given immediately after a thorough soaking, no

THE COMING WEEK'S WORK.

Extracts from a garden diary from May 27th to June 3rd.

During this week everything will be subservient to the bedding out in order to get the work done. When the work drags on for weeks it becomes tiresome, and the season is then so much shortened. I do a little carpet bedding which usually follows in the beds now occupied by the Tulips, and if the change in these beds are completed by the middle of June in so average a season it will do early enough for such things as *Coleuses*, and *Alternantheras*, and as these will be planted thick enough to be effective at once the beds will come on altogether. Top-dressed Melons with rather heavy loam, pressing it down firmly and pegging out the shoots in the right direction to fill the frames. Leading shoots will be stopped when within 6 inches of the sides of the frame, and the lateral picked one or two leaves beyond the fruit. I always endeavour to set as many fruits as will form a crop for each plant as near about the same time as possible so that all may start swelling together. If one fruit gets a long lead the other will not follow. Give liquid-manure to early Melons swelling out in a general way I think four or five fruits are enough on each plant, though this, of course, will depend upon how much space the plants are permitted to strike and fill a lesser space, and then a large number of fruits may be left. I certainly think a summer Melon plant should have more room for development. The more growth the more vigour. Draw more earth up to second early Potatoes, such as *Puritan*, *Snowdrop*, and others of similar habit and easiness. Use the fork between rows

INDOOR PLANTS.

STOVE DRACENAS.

AMONG the stove species and varieties of *Dracena* are to be found some of the most beautiful and distinct variegated plants in cultivation, alike remarkable for the charming colouring of their foliage and the elegance of their habit; they are adapted for the warm conservatory or the greenhouse in the summer, or the numerous decorative purposes in rooms for which plants are now so extensively used. The narrow-leaved kinds are the most elegant, but some of those with massive, broad-leaved foliage are very effective when associated with *Fernes* or flowering plants, and in these ways can be employed to the best advantage. All the warmer section will bear a stove temperature and are free growers, but do not progress so fast as to be of a weedy character. They are easily propagated, but not being plants that break out side-shoots, they do not afford material to make stock so quickly as many things do. They yield cuttings from the roots differently from most plants; the feeding fibres proceed from a stout underground stem, thick and blunt at the extremity, which extends downwards, soon reaching the bottoms of the pots. If 2 inches or 3 inches of these stems are cut off, and put point upwards in small pots, they will soon push growth, and, forming leaves, make plants similar in every way to such as are the result of striking the tops of the plants. The latter, if taken off with four or five leaves, root in a warm, close atmosphere in a few weeks, but the most expeditious mode of increasing *Dracenas* is to take the stems of any old plants that have attained a considerable height, and in such condition have generally lost their lower leaves; if these are divided at the roots, the soft portion of the top and all the leaves, and are laid down in a propagating frame where there is a

GOOD BOTTOM-HEAT, on a bed of open, sandy peat, with about half an inch of similar soil over them, most of the eyes will start into growth and push up sucker-like shoots. As soon as these have made three or four leaves each they should be cut clean off from the old stem, with the roots attached that the young growths will have formed; they should be put singly in small pots in sandy peat and kept close and shaded for a week or two, when they will soon get established, and must then be innured to the full air of the house. *Dracenas* are not liable to become drawn or weakly, but their leaves are handier and more enduring when they are grown with enough light and have a sufficient amount of air every day during summer. Plants raised in the above way early in spring will, if kept growing in a brick heat, be ready for moving into 4-inch pots by the end of June, after which continue to treat them as before, giving plenty of water so long as the season of growth continues. Syringe freely overhead in the afternoon at the time the house is closed. In the night through the winter a temperature of 60 degs. is sufficient; in the spring increase the warmth day and night, and as soon as growth commences move them into pots 3 inches larger, treating as in the previous summer. Additional root-room as wanted must be given proportionately to the requirements of the different kinds grown; such large growers as *D. Shepherdii* and *Baptistii* need much larger pots than the smaller sorts. The plants may be kept growing to any required height so long as they retain their lower leaves; after the loss of these they possess little beauty, and should have their heads taken off and struck, and the young stock raised from the stems. Three years is generally as long as the plants can be kept fairly furnished with bottom leaves. Comparatively small examples in 6-inch or 8-inch pots are the most useful for ordinary decorative purposes. There are now an immense number of species and varieties, many differing very little from each other. *Trips*, *red-spider*, and *aphides* can be easily kept under by syringing. Should brown scale or mealy-hug attack them, syringing is the best remedy. The following is a selection of the best heat-requiring kinds:—*D. albicans*: A very distinct and handsome sort; leaves bright-green, variegated with white. *South Sea Islands*. *D. amblyoneura*: Handsome in habit, the lower portion of the leaves heavily edged with bright-red. *Amblyna*. *D. angustata*: A handsome,

Dracena Goldieana. (See page 174.)

more will be required for a long time. It is also worth while to remember that though a little more expensive, plants turned out of small pots become established and begin to make a display much more quickly, as well as requiring much less watering, than the "cheap" bedding plants now so largely grown, and sold in boxes or trays. *Pelargoniums* of all kinds should be planted in poor sandy or loamy soil, as then they do not make too much growth, but bloom very profusely, and the same may be said of *Single Petunias*, and of *Marguerites* also to a certain extent; but *Verbena*, *Fuchsia*, *Begonia*, *Dahlias*, *Asters*, and many more luxuriant to a soil well enriched with plenty of very old hot-bed manure, leaf-mould, or spent hops, decayed turf, and so forth. In a fine season the Ivy-leaved *Pelargonium* make a grand bed if planted moderately close, and the growth pegged down, but not too stiffly, to the soil. A bed of a *Salmia* or delicate rose-coloured variety, such as *Mrs. Crocus*, "dotted" over with dwarf purple or lavender *Heliotropes*, the pretty "Blue" *Marguerite*, or even yellow *Begonia* or *Calceolarias* has a very pretty effect. The *China* or *Annual Asters*, *Stocks*, *Zinnias*, *Phlox Drummondii*, *French and African Marigolds*, and all similar plants should be planted out as soon as possible now, and must be kept moist at the root subsequently, though a mulch of fibre, spent manure, or the like, saves a lot of work in this way. Stocks are apt to flag badly after being transplanted, and must be shaded in some way from the scorching sun. Prepare beds for sub-tropical plants, such as *Cannas*, *Kolocas*, *Nicotianas*, *Melise*, &c., by digging them deeply and watering well. Plant out Tomatoes on warm borders, and keep them rather dry at the root at first. Seed of Chinese *Primulas* must be sown at once, also *P. obcordata* to flower next spring; seed of *Carnations* may also be sown, and the plants will flower next summer.

B. C. R.

of Potatoes just up. Stirring up the soil is of the greatest possible benefit at this season. Planted several long rows of the white seeded Runners; these are more useful for late picking than the Scarlet Runner. Peas in a dry time must have much and water or they will be short in haulm, and the pods small. Dressed *Morsillo* *Charities* with soap and Tobacco for black-fly. Where possible the shoots have been dipped in the liquid. There is less waste in dipping, and the insects get the full benefit. Trained cressets on walls. Looked over Peach-trees to still further thin the wood. Nailed in young shoots to prevent breakage from wind. Afterwards thinned off more fruit, and gave a good wash with soap-suds from laundry, with a dash of Tobacco liquor in it, or Tobacco powder will do just as well, and will come cheaper. Rearranged trees in orchard house to give Peaches more room. I always start the season with a few more trees than the house can hold when growth is active, and turn out some of the late Plums. When the weather gets settled early in June the Plums will be plunged in a boiler in a sheltered part of the garden. Looked over climbing conservatory to regulate growth. Moved out a few plants which have done flowering and filled up with *Fuchsias*, the *Double Petunias*, and formed a group of *Gladiolus* the *Bride*, which has been started in a cool pit to flower late. These are beautiful for cutting. I have had the large flowered hybrid *Gladiolus* beautiful in pots in May and June. The bulbs were potted in December, and plunged in a bed of leaves in a pit over the top of the pots till growth commenced. There was not much forcing, just a little genial warmth. Severe forcing will not suit the hybrid. Even the *Bride* if pushed too hard gets out of shape, and the leaves go wrong. Clematis is large and a strong man size are very showy things in June, and are quite difficult to grow. Prepared a lot of stakes of different lengths for hardy plants in borders.

URBANA-CHAMPAIGN

small growing kind; leaves 1 inch wide, dark, clouded green, shaded with bronzy-red. South Sea Islands. *D. Baptisti*: One of the finest of all the species. The leaves are large, and the general habit of the plant handsome. Ground colour, a pscular shade of rich, metallic-green, edged with red, suffused with white. South Sea Islands. *D. Bausei*: A distinct and handsome variety of garden origin. It has stout, broad leaves, dark bronze, edged with crimson; the stalks highly coloured. *D. Claudia*: A fine decorative variety of small habit: leaves green, shaded on the edge with rosy-carmine. A most useful kind. *D. Earl of Derby*: Leaves long and broad, ground colour bright-green, broadly edged with crimson; leaf stalks highly coloured. South Sea Islands. *D. Fraseri*: This sort has very stout, broad, short leaves; the ground colour is very dark, with red variegation. A distinct and handsome kind. South Sea Islands. *D. Frederici*: A hybrid variety; dark, bronzy-green leaves, edged and veined with crimson.

D. GOLDIEANA (figured on p. 173) is a most remarkable and distinct species; the leaves are broad and pointed, greyish-green ground colour, banded across with broad irregular markings of whitish-grey alternating with dark-green. Tropical Africa. *D. gracilis*: A small-growing kind with slender narrow leaves. A useful decorative plant. *D. Guilfoylei*: Another very distinct and handsome kind; ground colour light-green, striped with white, pink, and red. South Sea Islands. *D. Mrs. Bland*: A stout short-leaved variety, ground colour deep-green, margined with bright-crimson. *D. Princess Margaret*: Different in appearance from most others, medium in growth, midrib crimson, most of the leaf-blade white, striped with pale-green suffused with pink. South Sea Islands. *D. pulcherrima*: A medium-growing kind, with narrow leaves; very graceful in appearance; colour green, with red and white markings. South Sea Islands. *D. Rex*: A hybrid variety of distinct character; stout in habit; leaves bronzy-green, streaked and edged with carmine-red. *D. Shepherdii*: One of the largest and strongest growers of the family; the leaves are very long and broad, and of different shades of green, tinged with bronzy-red. South Sea Islands. *D. superba*: A small-leaved hybrid variety; leaves 12 inches long by 1 inch broad, bronzy-green, edged with red. *D. terminalis*: One of the oldest, but still one of the very best for general decorative purposes, grown more than all others put together for market, as it will stand much hard usage. Leaves bronzy-green, edged and suffused with pale transparent red. East India. *D. terminalis alba*: A form of the above with a good deal of white in the leaf marking. B.

ANTHURIUM SCHERZERIANUM AND OTHER KINDS.

CURIOUS enough, last week I was asked about *A. crystallinum* for flowerlag, and this week I am asked by "C. H." about the variety maximum of the species named above. This is at once a magnificent and a telling plant, and I was the more struck with this plant a few days ago than I have ever been before, when I saw two plants each having about a dozen spikes upon them. This variety is only a seedling variety of the original plant, which, when it first flowered in this country, produced a spathe about an inch across; but it soon improved in size and in colour, until I should think for a few years it was never out of demand, and I have sold an immense lot of it in every part of the three kingdoms, and I should imagine more money has been made by this plant than by almost any other one now plant; but this is nothing to do with its culture. It is a member of a very large family, some of which are magnificent when grown for ornamental leaves, others for the beauty of their spathes, whilst the great majority of them have nothing about them to attract, and are, therefore, best left to the care of botanic gardens, or some such establishments, where individual beauty is not so much studied and cared for. I have noticed a few kinds which are remarkable for the beauty of their spathes, and I must here call the attention of my readers to the fact that the beauty of Anthuriums does not lie in their flowers, because in all cases these are small and insignificant, but to the vivid colouring of a more or less large fleshy spathe, which in most instances forms a sort of covering to the

spadix, on which the flowers are congregated, and which are always hermaphrodites. This spathe, from its thick fleshy texture and from being entirely free from any functional duties, last a long time in full beauty, and it is for the beauty of these spathes that Anthuriums are grown. They are easily fertilised, and by this means some beautiful hybrid varieties have been obtained, a few of which I mention below—

A. ANDREANUM.—A robust plant, producing fine large cordate, smooth leaves of a leathery texture, and of a rich-green colour. The flower-stalks are thrown up above the leaves, and it produces a large bullate spathe of brilliant scarlet, the spadix being white, eventually changing to a lemon-yellow tint. It is a native of the mountains of South America.

A. FERRIENSIS.—This is a garden variety raised between the last named plant and *A. ornatum*. It produces a large spathe of a bright red, but it is not bullate, and a white spadix.

A. LONDINENSE.—This is another variety from *Andreanum*. It grows in the same way, and produces a very large spathe, bright rosy-carmine in colour.

A. REINE DES BELGES.—This is a very free-flowering variety, with a large spathe of a soft delicate rose.

A. LAINIE.—This, one of the varieties which has run away from the coloured forms, and the spathe is large and of the purest white, produced well above the foliage.

A. ORNATUM.—This is another pure white spathed plant with the spadix of a violet hue, and the flowers upon it are sweet-scented. It is an imported plant from Venezuela.

A. PARADISE.—This is a grand plant, a cross between *A. Andreanum* and *A. ornatum*, bearing a creamy white spathe, which is suffused with flesh colour, and the spadix a reddish salmon.

A. SCHERZERIANUM.—This is a dwarfier plant than any of the above, with long narrow leaves, which are leathery in texture and rich deep-green. This, the typical plant, produces spathes which are thick and fleshy in texture and ovate in shape, crimson-scarlet in colour, and the spadix yellow. It produces a vast number of spathes and is exceedingly ornamental. It was introduced from Costa Rica.

A. SCHERZERIANUM WILLIAMSII, of the same habit of growth, but bearing spathes of a pure white, the spadix being yellow. This plant originated in English gardens, but I cannot tell how. It has been much neglected, but I see lately some forms with larger spathes are cropping up.

A. SCHERZERIANUM ROTHSCHILDIANUM, raised between the two last named plants, and partaking of the character of both having the front of the spathe creamy-white, mottled and freckled with red, and the back part is wholly red.

A. SCHERZERIANUM ATRO-SANGUINEUM is a fine coloured variety, having a spathe of an intense crimson, making it a plant of a distinct and attractive character.

A. SCHERZERIANUM MAXIMUM.—This is a grand form introduced to notice by Mr. Wm. Bull, of Chelsea; it produces enormous spathes measuring some 8 inches or 9 inches in length, and about 4 inches across, of a rich-deep scarlet. Now I think my friend, "C. N.," will find enough kinds enumerated above, but if he makes up his mind to devote all his space entirely to the cultivation of Anthuriums he will soon learn the names of a lot more. They are plants that enjoy a great deal of heat during the growing season, accompanied by a lot of water to the roots and a moist atmosphere, so let the pots be well drained in order to carry the water away quickly. For soil use good fibrous peat and turfy loam made sandy, which should be pressed down firmly. During the winter months the temperature must be considerably lower, but they will do best if the glass is not allowed to fall lower than 60 degs., and, of course, less water must be used in the winter than the summer. J. J.

3223.—*Ferne and Palms for a conservatory*.—There is a good selection of *Ferne* to select from, and you may include the following with every prospect of succeeding well in such a structure: *Pteris serrulata* and any of its many varieties, vigorous plants that will succeed well in small houses; *P. tremula*, not forgetting the very charming variety named *variegata*, which is distinctly marked with silver white

P. roties, a very sturdy *Ferne*, and its variety *albo-lineata*; *P. c. nobilis*, which has its fronds distinctly crested; *Adiantum cuneatum*, some of the finer varieties of the hardy *Ferne*, *Shield Fern* (*Polystichum*), *Moss Fern* (*Lastrea*), forms of *Hart's tongue*, *Onychium japonicum*, *Asplenium*, and I may mention *Pteris Mayi*, a crested form of the variety *albo-lineatum*, and a very distinct kind. All the above-mentioned *Fernes* thrive well under ordinary conditions, and will make a good commencement for your collection. A few good *Palms* are *Rhapis flabelliformis*, *Chamaerops humilis*, *Corypha australis*, *Latania bharbonica*, and *Areca lutescens*, which you may commence with. They are not troublesome to grow, and small plants are not expensive. Give the plants as much shade as possible, as the house is so exposed to the sun, and abundance of water, which may be lessened in the winter, as then the soil requires to be kept drier. Another point of importance is to keep the leaves sponged occasionally to remove dust, as plants, when in houses near the dwelling-house, often get much coated with dust.—C. T.

3337.—*Unhealthy Orange trees*.—*Orange-trees*, like other fruit-bearing trees, are frequently injured by overcropping, and something of this sort seems to have been done in the present case. Allowing one tree, probably a small one, to bear 100 Oranges is not wise as regards the future. But it may be fairly assumed that when the leaves of an *Orange-tree* fall off that there has been some irregularity with the roots, either in supplying water or the drainage is stopped up, and the soil has, in consequence, become sour. It will be best to examine the condition of the roots. Something is wrong there.—E. H.

—It is very difficult to answer questions when no information is given as to the treatment of the trees, or where they are growing. They must have received a check in some sort of way, either by exposure to the drying winds, or too much or too little water at the roots. *Orange-trees* are not at all difficult to manage, either as greenhouse plants or grown in a forcing-house; but the pots or tubs in which the plants are growing should be well drained, and water must be applied with discretion, and it should be as warm as the temperature of the house.—J. D. E.

—Evidently the roots have from some cause, over-watering probably, become unhealthy. Possibly the drainage has become clogged, and the soil has thus been rendered sodden and sour. It is seen to at once, and the plants are very carefully watered and attended to in other ways they may pull round, but in all probability they will succumb. They appear to have been over-cropped also.—B. C. H.

3332.—*A lean to greenhouse*.—*Tomatoes* will not do much good in a north house. The plants would grow, but the crop must be a poor one, and if the end of the summer happened to be cold the fruit might not ripen. The treatment of *Tomatoes* is simple enough, and may be summed up in the words—Keep the growth thin; and this would be doubly necessary in a house with a bad aspect. Details of treatment for *Tomatoes* are frequently given in *GARDENING*, and regular readers may always find solutions to their little difficulties in the back numbers.—E. H.

—I am afraid that you will not achieve much success with the *Tomatoes* in such a position as that described. A plant-house right in the shade, as described by you, will not grow *Tomatoes*, which require a large share of sun. If you have a sunny wall it would be better to plant them there. I have got a very good crop of *Tomatoes* from quite a small garden when the plants have been against a wall with the sun upon it the best part of the day, and the soil fairly good; but sunshine is essential.—C. T.

—I cannot hold out any hope of *Tomatoes* doing much good in a place like this. They delight in, and, indeed, positively require, plenty of light, air, and sunshine, and in a dark or shady house run almost entirely to growth, and produce little or no fruit. Cucumbers would be much more likely to succeed in such a house, if kept close, warm, and moist. But decidedly the best kind of occupants for a structure situated as this one is would be *Fernes*, *Palms*, *Dracenas*, and other foliage plants, with a *Lagerflora* or some *Fuchsias* in the way of plants.—E. H.

3745.—Greenhouse plants from seed.—Almost the only winter-flowering subjects that can be raised from seed sown now are Chinese Primroses (*Primula sinensis*) single and double, and Cinerarias. Seed of both should be sown at once in well-drained pans (or boxes) of a light and porous mixture of loam, leaf-mould, Coco-nut-fibre and sand, covering the seed with a very little fibre only. *P. obconica* sown now and grown on briskly will bloom nicely next spring. Mignonette may be sown in pots in August for winter flowering. It is too late now to sow *Cyclamens* to bloom next winter.—B. C. R.

3764.—Seedling Begonia-tubere.—I fear the tubers are all "dead as door nails," and past recall. They were probably kept too moist in the early stages—the soil they are planted in ought to be almost dry until growth has fairly commenced. Of course, the tubers may not have been sound when received, though this is very unlikely, unless they got a touch of frost in transit. I lost more tubers last winter than ever before, owing probably to their not having ripened properly in the autumn, and I have also found them to start more irregularly than usual this spring; but there must be something more than this to account for the loss of an entire dozen.—B. C. R.

3766.—Calceolariae from seed.—The Calceolaria is an easily grown plant, and seldom goes wrong if its simple requirements are attended to. I had some this year which drooped and showed signs of dying, but I fancied the reason was an overdry atmosphere, caused by too much ventilation during the drying east winds we have lately had. I gave the house air only at the top in the day-time, and was careful to damp up the house frequently. I lost two plants which were too far gone before I noticed them; the others speedily recovered, and the drying winds not being allowed to blow directly upon the plants, they are again in great beauty. Too much cold well water will also cause the plants to lose their lower leaves. Green-fly too is the desperate enemy of the Calceolaria, and must never be allowed to gain a foothold. A low temperature suits the plants better than a high one.—J. D. E.

3767.—Carnations (Malmaleon, &c.)—Striped Malmaleon (Lady Middleton) and Mme. A. Wareque can be obtained from any of the large florists. Mrs. Reynolds Hole, Germania, Mrs. Wier, &c., are much better out-of-doors, and if the flower-spikes are drawn up 22 inches already, they are weak. Even now it would be better to place the plants out-of-doors until the flower-buds show colour; but if the flowers are wanted early, place the plants with the flower-buds near the glass roof. Indeed, this may be better, as they might get a serious check if cold weather set in as soon as they were put out.—J. D. E.

3762.—Tuberous Begoniae.—The plants will go out from the boxes right enough, especially if a little firm light sandy soil is used round the roots, to give them a start, and they are kept well watered until they become thoroughly established. But if the plants are now growing fast, and may become crowded if left as they are, it would be better to pot them off singly into 3-inch sizes, as it is seldom safe, even in the southern parts of the country, to plant these Begonias out-of-doors before the second week in June. The others also had better be repotted if they are getting at all root-bound in the small pots they now occupy.—B. C. R.

2739.—Acacia armata and Oyticus in pots.—As soon as the plants are done blooming cut them back, leaving 2 inches or 3 inches of the wood made the preceding season. This keeps them dwarf and bushy, and induces the formation of strong growths. When the young shoots are about an inch long shift into the next sized pot, using good loam, with a little leaf-mould for the *Oyticus*, adding some peat for the *Acacia*. Attend well to watering, and as soon as growth is completed put them in the open air till the middle of September. A temperature of about 45 degs. in winter is enough.—J. C., *Byfleet*.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings should be engraved in the best manner, and will appear in our course in GARDENING ILLUSTRATED.

OUTDOOR PLANTS,

A USEFUL PLANT.

COREOPSIS ARISTOSA.

THIS is one of the most showy and, at the same time, one of the most graceful of all late-blooming Composites, and, like its congeners, *C. lanceolata*, *C. integrifolia*, and several others, it is a native of Carolina and the humid marshes of Illinois. It succeeds well treated as an annual in our gardens, and, together with its allies, is valuable in a out estate, affording, as it does, a profusion of bright-coloured, slender-stalked blossoms at a time when really elegant and beautiful hardy flowers are scarce. It was, I believe, introduced to our gardens by Mr. W. Thompson, of Ipswich, to whom we are indebted for so many handsome Composite plants. The illustration represents the natural size of the flower; it is a rich golden-yellow in colour, the disc being spotted with crimson-brown. It is difficult to imagine any golden-tinted flowers more beautiful than those of the different species

views with the flower centres of Holland for interest and beauty. It is a veritable farm, about thirty acres covered with bulbs and placed on the outskirts of the picturesque common of Ham, which may be seen from the famous terrace at Richmond. Mr. Walker, who owns this farm, simply grows the bulb for the sake of its flowers, which, through the best conditions of culture being afforded, are twice the size of those in ordinary gardens. They are skilfully farmed, the soil well manured and cultivated, and the bulbs for the most part lifted each year. It is a ewot picture on a sunny spring day to see the waving masses of glaucous leafage glistening in the sunlight, and the flowers dancing in the breeze. The foliage of the Daffodil seems to reflect the sunlight; it is like a shimmering sheen of silver, anouget which the flowers appear in countless numbers. Note the various forms of leaf, some broad and robust, others like Grass, swaying with the least breath of wind, whilst there is a delightful expression in the flower. The Daffodil repays study. Florists have named about five hundred varie-

Coreopsis aristosa.

of *Coreopsis*, especially when their graceful stems are inserted in a crystal vase and their flowers contrasted with the rosy, purple, and lilac tints of autumnal *Crocuses* and *Colchicums*. B.

USEFUL DAFFODILS.

THE Daffodil often meets with unpleasant experiences in an English spring, cold, blustering winds, spells of brilliant summer sunshine, and heavy rains trembling the fair flowers; but, in the face of such obstacles, it has made great strides in popularity during recent years. The outcome of this enthusiasm over its many forms is a remarkable increase in the cultivators of the bulb. We have had species imported from the Pyrenees through Mr. Peter Barr, well known to lovers of the flowers as an ardent enthusiast, and many beautiful kinds have been raised by what is known as cross fertilisation; but there is an element of novelty in a Daffodil farm. I have seen the flower farms in the land of the Dutch, the broad acres of Hyacinths and Tulips that follow the ground with brave masses of various tines from white to the richest orange, yet a Daffodil farm a few miles from London

ties, many, of course, differing merely in degree; but yet there is a degree, and often most marked. Sometimes the chalice, cup, or corona, as the centre is variously called, is elongated into a robust, bold trumpet, or so reduced, as in the Poet's Narcissus, that it is almost abortive. The petals exhibit the same difference in form, this variability of expression increasing the pleasure that the Daffodil fancier evinces in the many children of our wilding Lent Lily and the Poet's Narcissus. The bulbs are

PLANTED in long beds, about five lines in each, the number depending upon the constitution of the variety, and the soil is raised a few inches above the level. This is done to protect them as much as possible from the influence of damp, the Daffodil under cultivation showing its dislike to such conditions by making miserably poor growth. It loves to dwell in the open field, in full exposure to every ray of sunlight that may dart upon the leafage and reflect its silvery tone, repaying the grower with flowers of remarkable vigour, reds health written upon the massive segments. Produce of this character is eagerly purchased in Covent-garden-market even in the face of severe competition from

other lands. We hear much of the Scilly Islands, the Mediterranean region, and other spots in which flowers colour the landscape and provide delightful pictures for the artist, but few know of this English Daffodil farm, where acres of bulbs toss their flowers in the breeze, and the grassy growth bends gracefully as the tall Grass of rich meadow land. The land is very flat, and the whole prospect as one enters the gateway comes before the eye at once. It is strange that, although there are hundreds of kinds, about twelve only are considered of value for the market, and for one of the finest of this select number, named Horsfield, we are indebted to a Lancashire weaver named Horsfield, and this fine flower, with a similar kind named Empress, that expands its flowers a few days later, are two of the most largely grown types at the present day. Many an earnest mind is at work amongst the flowers in the suburbs of great cities, and in the North of England the most ardent amateur Soriate are the mechanics who find recreation in their spare time by raising

NEW FORMS of their special favourites. Empress is, perhaps, the most popular Daffodil, and is called a trumpet kind, through the shape of the calice or corona, this being like a trumpet, a rich contrast to the pale yellow perianth or segments. It is very hardy, the flowers last long, and make a brave show, as may be seen from their effect in the large bunches at our markets and on the street barrows. In the month of May the grounds at Ham are white in places with the Poet's Narcissus, the flowers of the purest white, and deliciously perfumed. The double variety is like a Gardenia in form, and one of the most popular hardy bulbs in England. The Daffodil at Ham are treated in a thorough market way. Men and boys may be seen picking the most forward flowers to expand in their full freshness and beauty under glass, and when on the point of full expansion, they are transferred to a large flower shed, where rows of women work at benches, bunching the fragrant blossoms into "twelves" for the market. The stems are cut of one length, and the peculiar disposition of the Daffodil, the flower being placed at right angles to the stem, permits of ready bunching up. England is an excellent bulb country, but with peculiar persistency we go to the Low Countries for supply, although our native soil will yield, if properly worked, splendid produce.

C. T.

3724.—Moving a Christmas Rose.—Are you obliged to transplant? If not, I should say let the plant remain undisturbed, as removing old-established Christmas Roses is fraught with some danger. In moving old plants the best way is to divide them into two or three pieces, so that the roots come into contact with fresh ground. The roots are very brittle, so that lifting must be carefully done, and as much of the old earth as possible must be worked away from the roots. I have found the best way to effect this is to work away a good portion with a pointed stick, and then wash away the remainder by pouring water on the roots.—J. C. B.

3771.—Flowers for a sandy soil.—It is a matter of some difficulty to grow hardy flowers successfully in such porous soils, but much may be done with deep culture and mulching in the summer-time. The ground should be trenched 18 inches deep, so that the root can go down for moisture. Planting should be done in the autumn, or early in winter, and at the beginning of April. I should mulch with two or three inches of the Peat-Moss-litter which you say can be easily obtained in the neighbourhood. Even the hardier kind of Roses may be fairly grown in this way in the most porous soils. A little clay would be of immense value.—J. C. B.

3758.—Plants for a Birmingham garden.—If Lettuce "luxurians," the soil must be fairly rich and good, and probably all it requires is a dressing of lime to sweeten it and enable other things to be grown. Of vegetables, Rhubarb, Celery, Cabbages, Sea-kale, Scarlet Runners, Dwarf Beans, Onions, and Jerusalem Artichokes, will be more likely to succeed than most others. Of flowering plants you may have Chrysanthemums, Helianthus, Daisies, Torch Lilies (Tritomas), as well as

the old White Garden Lily (L. candidum), L. tigrinum, L. aurantiacum, and others, Veronicas, Evening Primroses, Lupins, Campanulas of several kinds, Doronicums, Spiraeas, Primroses (single, coloured, and Hybrid), but no double ones), Everlasting Peas, perennial Phloxes and Sunflowers (Helianthus), Pyrethrums (P. roseum, var. P. parthenium fl. pl. and P. uliginosum), Auriculas, Thrift, and some others. You may also sow seeds of Mignonette, Cornflowers, Annual Chrysanthemums, Helichrysums, Astors, Stocks, Sunflowers, Tropaeolums, French and African Marigolds, Godetias, &c., and Petunias, Verbenas (seedlings of both best), Calceolarias, Lobelias, and Golden Feather, some "Germanias," &c., may be tried. The old-fashioned Marvel of Peru is a capital town plant, and so is the pretty little "Creeping Jenny" (Lycimachia Nummularia).—B. C. K.

3743.—Auriculas in the open air.—The only Auriculas that succeed in the open air are the alpine varieties, as they are formed, for in truth they are all alpine plants, and are perfectly hardy; but the great beauty of many of the show Auriculas consists in the dense coating of farina (a fine white powder) on the leaves, and also upon the flowers, for although the green-edged have no powder upon the edge of the corolla, the centre part of every one of them has it densely laid on, and a shower of rain—a drop of water even—will scatter the powder over the ground colour and the green edge. The plants can easily be raised from seed, which should be sown in flower-pots or seed-pans early in the spring (February). Seed sown at that time will, with good management, produce flowering plants for next year. By good management I mean pricking the plants out in small seed-pans or shallow boxes, and when they are large enough planting them out carefully where they are to flower, about 9 inches asunder. The plants may remain in the same position for three or four years; but they require to be kept moist at the roots during the summer, and dead or decaying leaves should be removed in the winter. Seeds may be sown now, but the plants will scarcely flower next year. Plants may be had from any good Soriat. Plant them now.—J. D. E.

— "Rus" enquires about growing Auriculas in the open air. I should advise our correspondent that alpine ones should be grown. Living near the sea, or otherwise, they should never be placed under the drip of trees. "Rus" can please himself whether he sets seeds or not, or procures plants. If plants are suitable, set in the autumn, say beginning of September, as for some years the weather has been too dry for spring planting. If "Rus" is enthusiastic about the Auricula, by all means let him sow seeds under a frame or hand-glass in February, as soon as possible if mild weather. If "Mr. Rus" has read Darwin's work on forms of flowers, he will perceive that the terms "thumb-eyed" and "pin-eyed" are mentioned, which forms when mutually crossed in the Auricula, Polyanthus, and other members of the Primrose family, are sure to be productive of seed. Green, grey, and white, colts included (not alpine), not to be grown outside. These are especial pets of the Soriat. The least shower of rain washes the meal off the plants, and their beauty, although they possess thickness of petal, is destroyed for the season.—F. M. KENDERLINE.

3740.—Lily of the Valley and Carnations.—It is easy to have Lily of the Valley before Christmas by potting up the crowns as soon as they can be obtained. Start them into growth at once in a forcing-house, and if there is a gentle bottom-heat the plants will do all the better, for the bright-green leaves will be produced with the flowers; the flowers will come without the leaves if there is no bottom-heat. The Carnations usually grown for profit are the Malmesbury, the pink and bluish variety. Mme. Arthur Waroche is a crimson form, and Lady Middleton, a striped form, are in cultivation, but not often grown for market. Germania (yellow) is a good market variety.—J. D. E.

3818.—Phlox Drummondii.—I always peg down the shoots of this Phlox once, when they have grown 8 inches or so long. If the plants showed any sign of not covering the soil properly I should not hesitate to peg them down even a second time. If they are not pegged

down at all the plants must be put out closer together to enable the bed to be filled; there is then a risk of the shoots growing too tall towards the autumn; if this should be wet the leaves are apt to rot, and thus render the bed unsightly before the flowering season is past. It is not necessary to plant anything as an edging to a bed filled entirely with this Phlox; it makes a very good edging in itself.—S. P.

— It may be grown with or without an edging to the beds of a different kind of plant. Large beds, I think, look best with an edging of some contrasting plant round them. The Phloxes will make the best mass pegged down, as the habit without pegs is straggling and rough.—L. H.

3872.—Seedling Violets.—Far better to get a few roots of the Czar, if you require single Violets for flowering in the open, or a few plants of a double sown sort, if you have a cold frame in which they can be put in September. These will give you blooms all the winter. Most likely these seedlings will be useless when they come into bloom. Violet culture is simple. Well dig a piece of ground in the open, or if at the foot of an east wall all the better. Do not make it too rich or the plants will run all to leaf. Plant the runners singly in rows 10 inches wide. Every bit with a root attached will grow, although it is not wise to make them too small. Keep the plants shaded and watered for a week or so after planting if the weather is hot and dry.—S. P.

— Certainly not a day should be lost in transplanting the seedlings, which if fairly strong now will make good plants by next spring. The ground should be well dug over and rather liberally manured, and the seedlings must be kept regularly moist throughout the summer. Most, if not all, of them will flower next spring. Be sure to make the soil quite firm around the roots.—B. C. K.

— The seedlings may be transplanted and well watered any time when large enough. The strongest will bloom next spring, but not so well as plants obtained from runners, or even by dividing old roots.—L. H.

3827.—Wallflowers, &c., from seed.—It is really not advisable to waste time over your own seed now that seed can be had so cheaply, and from such good strains of each. If "Amaturias" however, is desirous of saving his own, fertilisation is not necessary. All that is required is to keep each kind distinct, by growing the plants clean away from any other plants of the same family, or the seed is certain to be mixed; the pollen is carried from one to the other by insects. When the plants are in flower, any that exhibit traces of a want of distinctness or inferiority in habit of growth should be destroyed. This weeding-out of undesirable plants tends to keep a good strain of any kind of flower in perfect condition.—S. P.

— It is not necessary to fertilise these or Sweet Williams artificially for seed purposes. But to improve the stock pull up all plants bearing inferior flowers as soon as their character can be seen.—L. H.

3820.—Tropaeolum speciosum and Tussilago frugans.—Both are perfectly hardy in any county in England. The former is not easily established in any situation, except in a northern exposure; indeed, it seems quite useless to attempt it anywhere else. It seems to require a cool base for its roots, and then should have protection from cutting winds until it is 1 foot high. A few slates set on edge will effect this around the tender shoots. It is not partial to any kind of soil, but should have abundance of moisture about the roots during dry weather. The Tussilago will grow anywhere, but the flower-stems are not hardy. They need protection; otherwise the plant is hardy enough at the roots.—S. P.

— The Tropaeolum is perfectly hardy in any well-drained soil, not only in Surrey, but in quite the north of England as well. In the south the great thing is to keep the plants cool, hence they thrive best on the north side of a wall or building of some kind; they seem to thrive best in a rich moist soil, composed largely of leaf-mould, etc., with some sand. Tussilago frugans is a perfectly hardy native plant, and will not only grow but increase rapidly as well in any kind of soil of a fairly free and good description.—B. C. R.

— Tropaeolum speciosum is an easily grown plant if the climate suits it, but it cannot thrive in a dry soil and an atmosphere well on the dry side. It is a Chilean plant, but is quite hardy. It is seen at its best in the moist climate of the south-west of Scotland, where a traveller had seen three of four times and always found it ripening. He enquired of a native "if it always rained here?" "Na" was the laconic answer,

"It somotimoo snaws." In County Wicklow, in the garden of Phineas Rial, Esq., I saw it clambering over the garden walls and smothering the trees with great masses of its scarlet flowers. Mr. Paul grows it and flowers it in his nursery at High Beech, Essex, but it does not succeed with me in another part of the same county. The plant makes long underground rhizomes, and if planted in a soil that is almost constantly moist will succeed very well. A peaty soil suits it. *Tusilago fragrans*, or, more correctly, *Petasites fragrans*, is an easily-grown plant. It produces its flowers in February amid frost and snow sometimes. These are white and very sweetly scented. I find it succeeds admirably under a wall, where the flowers have a better chance to come to perfection. They flower best under a south wall, but the plant itself will grow quite as freely with a north aspect. They will both stand the winter in Surrey.—J. D. E.

— This is a delightful creeping plant, and produces a profusion of bright vermilion-coloured flowers, and is hardy. It would thrive in your Surrey garden perfectly well, if the surroundings are suitable, preferring a moist position, and good deep soil, yet light, whilst in summer a mulch of manure will be beneficial. I have seen this creeper very heartful with its shoots over shrubs, the gay flowers in bold relief. Spring is the time to plant, and when in full beauty this *Flame Nasturtium* is very striking. Coolness and moisture are the two chief things to consider. The familiar *Winter Heliotrope* (*Tusilago fragrans*) is a very easy plant to grow, and, in fact, is almost a weed. If you have a spot in the garden where it is difficult to get anything to grow satisfactorily there you can establish the *Coltsfoot*, thriving even in the shade, therefore useful for the shrubbery. I know an old garden where against the rockery in the shade there is a large mass of this flower, and it is perfectly at home in the poor soil. The flowers are of a pale-purplish colour, and very fragrant. They may be gathered in winter, and a few in a vase will scent a large room.—C. T.

giving a moderate shift if they are to be grown on to larger sizes; still keep close, and water cautiously for a time, and when a fair amount of growth has been made, gradually accustom them to plenty of air and sun, and remove to a sunny spot out-of-doors for a few weeks in August. Plenty of water and some weak liquid-manure must be given when the plants are in full growth, and the pots full of growth. *Libonias* require much the same treatment, but should not, as a rule, be pruned quite so much as the others.—B. C. R.

— *Deutzias*, being hardy shrubs, should be plunged outside as soon as the growth gets firm, but not forgotten. *Libonias*, being tender, should be kept under glass till July, and then placed outside to ripen growth.—E. H.

SUMMER-HOUSES IN THE GARDEN.

MUCH may be done by simple means to make the garden a pleasant place, and few structures are more effective and agreeable to use in hot weather than summer-houses, a very good form of which is here shown. These buildings

in the ground. In putting out the young plants I always give them 1 foot each way, taking the plants up very carefully and planting them with the trowel, and if the weather is at all dry I give them a good watering. As the summer advances the plants will throw out a lot of suckers, which should be taken off as soon as they appear, for if left on for any time they take the strength out of the plants and thereby loosen the amount of flowers. The Dutch hoe run between them will also help them by keeping the ground clean and free from weeds, as well as preventing the soil becoming baked. In preparing the frames in which they are to bloom, I find that a hot-bed which had been made up late in the summer, and from which all the heat is not spent, is as good as any. It must face south, so as to get all the sun possible. If such a bed is not to hand, make up a hot-bed and let it stand till all the rank heat has passed out, then put the frame on, taking care to allow 1 foot all round, so as to be able to give a lining as the sharp weather comes in. Fill the frame half full of leaf-soil and that from a Cucumber or Melon bed, half of each, taking care to fill the frame so that the plants will not be more than 8 inches from the glass. In putting the plants into the frames take care not to crowd them. The best sorts, I find, are *Marie Louise Comte de Brazza*, and the *Czar*. I also grow a small single one. It is not much larger than our common blue *Violet*, but very free-flowering, very early, and not quite so dark in colour as *The Czar*. I grow the single varieties like the *danilo*, only instead of lifting them in the autumn I put a frame over them and let them stop in their summer quarters. By leaving what runners come after September, they will start to flower and keep on till late in the spring; in fact, a few *Violet* blooms can be had all the winter with very little trouble, only just keeping very sharp frost from them. This can be done by covering the frame with litter or Bracken.

OUR READERS' ILLUSTRATIONS: A SINGLE SUMMER-HOUSE. RECEIVED FOR GARDENING ILLUSTRATED from a photograph sent by Mr. Alfred Burgess, Stewart House, Uxbridge.

can either be thatched or covered with living climbers.

VIOLETS FOR WINTER FLOWERING.

Now that the time has come for preparing the stock of *Violets* to bloom next autumn and winter, a few notes on their cultivation may be of use to some of your readers. Many cultivators of *Violets* advocate raising the stock from cuttings, but I have not found outtings half so satisfactory (besides taking more time) as pegging each runner into some good light soil, as in the case of *Strawberry* runners. I mostly use some finely-sifted leaf-soil, into which the runners quickly root, and in about a fortnight or three weeks they are ready to go out into their summer quarters, which should have a southern aspect, and if slightly shaded from the midday sun, so much the better. Give the ground a good dressing of well-rotted manure from an old hot-bed, and dig it well in to the depth of 1 foot or more, as in raising some clumps last autumn I found roots quite 1 1/2 feet

PLANTING OUT GREEN-HOUSE PLANTS.

At this period of the year a great many plants that have either finished their blooming for the season, or that do not flower until quite late in the autumn, are transferred to the open air, and the question arises as to whether it is preferable to keep them in pots, or plant them in the open ground, and with many the question of which system will be the best, as regards economy of labour; for with the number of plants usually grown in pots, and daily requiring attention as regards water, there is a great inducement to get a portion of the stock in the open ground, where they will at least be less liable to injury from drought, and the following subjects may safely be planted out at this date, and lifted in autumn, thereby saving a good deal of work, and mostly producing far better plants than by continuous pot cultivation.

CALLAS are now so largely grown for indoor decoration, or cut blooms in winter and spring, that it takes a good deal of space and labour to daily attend to the stock in hot summer weather, but if planted out now, and one good soaking of water will last them for a long time, as the old foliage will then die down, and they will soon start into a sturdy vigorous growth, and make splendid plants for lifting in September.

CHRYSANTHEMUMS: To grow a collection of these in pots means a considerable amount of work, as the waterpot is needed both morning, noon, and night; but very useful plants for decoration and supplying ordinary cut bloom can be grown with far less labour by planting out healthy young plants about 2 feet apart, and

3815. — Treatment of *Deutzias* and *Libonias*.

If the plants require more rooting space now is the best time to repot, giving at least a couple of inches more space. If the pots in which the plants have flowered are anything over 8 inches in diameter they will not require more room. A top-dressing of loam and horse-manure in equal quantities will suffice. In potting do not interfere with the roots any more than is absolutely necessary. A compost of three parts loam to one of peat and leaf-soil will suffice. Pot firm and stand the plants in the warmest end of the greenhouse until new growth is made, afterwards a sunny position out-of-doors, plunging the pots in ashes or Cocoa-nut-fibre refuse, will suit them best. When the newly-potted plants are well established in the new soil copious supplies of liquid-manure twice weekly will be an advantage. Syringe the foliage overhead daily in bright weather.—S. P.

— Cut the plants of the former back at once, more or less, according to whether you want large or small plants next season. If they are desired to increase in size to any extent all that will be necessary is to thin out some of the smaller spray, and shorten the strong branches slightly, but if not they may be cut back quite hard. After pruning keep the plants moderately warm and close, sprinkling them overhead once or twice daily, but giving water rather sparingly at the root. As soon as they have fairly broken into growth again repot,

lifting, and potting just as the bloom-buds are expanding.

DEUTZIA GRACILIS, one of the most useful of all white flowers for forcing in winter and spring, if cut hard back, and planted out now in good soil, it will perfect splendid growth by the autumn. Or a better plan is to let the plants rest for one season, and by having enough stock to force the plants in alternate seasons.

LILY OF THE VALLEY is in such great demand that one can hardly get overstocked with it. Directly my plants cease flowering in pots they are gradually hardened off and planted out in beds between dwarf fruit-trees, where they remain a couple of years, when splendid plump flowering crowns are again in readiness for forcing. Some say imported crowns are the best, but if they treated home-grown ones well they would have no cause to complain, either of the quantity or quality of the bloom.

SIBYRICA JAPONICA, a most valuable plant, as not only the bloom but the foliage is highly ornamental. It succeeds remarkably well on the planting-out system, but needs a moist situation or copious supplies of water at all times. A partially shaded place suits it well, and in the open air it is valuable for out flowers.

SOLANUM CAPSICATRUM (Christmas Cherry) is a valuable decorative plant, and succeeds admirably planted out. I cut the plants down quite close in March, and place them near the glass to break into fresh growth, the young shoots being pinched to ensure plenty of shoots. They are planted out in May, on good soil, in an open, sunny spot. They develop fine heads, loaded with berries, and may be lifted in September.

J. GREEN, Gosport.

HOUSE & WINDOW GARDENING.

FIBROUS-ROOTED BEGONIAS AS WINDOW-PLANTS.

THE Begonia tribe, whether tuberous or fibrous-rooted, are specially suitable for room-culture, for they have a power of adapting themselves to circumstances which few other plants possess so strongly. The great improvement in type which has been effected in both classes of late years, by careful hybridisation and cultivation, is astonishing, and the fact that some of the Fibrous-rooted Begonias have been fertilised with the pollen from fine large-flowered Tuberous Begonias, has opened out a prospect of endless new varieties, combining both the wonderfully rich colouring of Tuberous Begonias with the perpetual flowering habits of those with fibrous roots. One of the finest of these is "John Heal," with bright-carmine blooms about 2 inches in diameter, borne in racemes containing eight or nine blooms each, which stand well above the foliage, making a very handsome table-plant, which will flower several times in the year, according to the amount of warmth they receive and other care. None of them are difficult to grow; they only need careful repotting without much disturbance of the soil. Whenever the pot becomes full of roots, with a little cutting back into shape, if necessary, when they will burst again into full bloom in a sunny window or a warm greenhouse. Leaf-mould and turfy-loam, with a little soot and sand, suit them better than too much manure, which should be very old, if used at all; but they like a top-dressing of rich soil when in bloom, and a plentiful supply of water. Begonia Carrieri, a most floriferous variety with pure white flowers, can be had in bloom all the year round by means of cultivating two or three plants, which can alternately bloom and rest, but for this, of course, fire-heat is necessary in winter. One of the best varieties for early spring is B. Knowsleyana, with pink blooms of a delicate shade. B. Gloire de Leaux, too, is excellent for spring work, and has the additional beauty of rich-bronze foliage, with bright rose-tinted flowers, which are most useful in January, when the first bloom for the year opens. B. semperflorens gigantea, with enormous heads of rich-carmine bloom, is a splendid plant, constantly flowering throughout the year, and B. Weltonensis is perhaps the best Begonia of a pink shade for late autumn and winter work. Every one of these make excellent decorative plants for the table, and do not appear to object to the atmosphere of a room so much as many other flowering plants. But they will not stand gas, which

makes them drop their pretty blossoms immediately, and it is well to protect them from sharp draughts, which sometimes have the same effect. Soot-water given once or twice a week in a clear, weak state will suit them well whenever they are growing fast and making fresh bloom; but they do not need it when they have been lately repotted.

L. R.

Dwarf Arum Lily (Richardia nana) for a room.—The great popularity of the ordinary Arum Lilies (Calla Richardsoniophica) is equalled but by few other flowers; but from their large size they are unsuitable for table decoration, and are, therefore, but little grown in rooms, as they otherwise might be. This defect (so far as table decoration is concerned) is quite removed by the introduction of the Little Gem, a Calla or Arum Lily, exactly corresponding with the larger variety in every particular except its size, which is about half that of the ordinary Arum, the flowers being pure-white, of which it throws up four or five blooms from one crown, the whole plant being usually about 18 inches in height. Nothing can be more perfect than a well-grown "Little Gem" Arum Lily for the drawing-room, or centre of the dinner-table, the pure white blossoms and handsome shining foliage being singularly attractive. The "Little Gem" can be cultivated exactly like the older variety—i.e., turned out of its pot, as soon as it has done flowering, into good rich garden ground, a trench, made as for Celery, being an excellent place for this plant. Here it will gradually ripen its leaves during the summer, and become very strong, so that when the roots are raised early in September (before frosts begin) they can be divided into several separate single roots or crowns, each of which should be placed in a 5-inch pot, with rich soil and good drainage. After standing for a week or so out-of-doors in the shade (the pots resting on a bed of ashes), they should be removed to a sunny window, where they will bloom about January, if the temperature be kept up by a dolly fire. Green-fly must be sponged off directly it appears, and the foliage kept clean; a plentiful supply of water is necessary to all Arums, as they are semi-aquatic plants, and they must not be neglected in this particular, even during their time of rest in summer.—I. L. R.

THE KITCHEN GARDEN.

CUTTING ASPARAGUS.

STRANGE as it may appear, there is a great difference of opinion on what may seem to some people such a simple operation as cutting Asparagus. Cutting off the tops of any plant will exhaust it more or less, and, as is well known, it is the continual cutting off of the heads of any perennial weed or plant which will kill it in time, and which is adopted in many cases to destroy obnoxious weeds. This illustration holds good in the case of Asparagus. Judging by the extent to which outlog is indulged in by many people, one would think that this homely vegetable was endowed with everlasting life. In scores or even hundreds of instances the languishing state of the beds is entirely due to overcutting. In some instances employers are to blame for this, for they will keep on having Asparagus as long as possible. Often have I been called upon for extra dishes of Asparagus after cutting had been given up, but I have always been able to show how very unadvisable it is to cut late in the season, and that if cutting is indulged in late the plants will be weakened accordingly and possibly fail to give good heads the following season. Another reason for late cutting is that Cauliflowers and Peas are often late. If

LATE ASPARAGUS is looked for, the beds will have to be provided for the purpose, and to be done away with when worn out or rejuvenated by foregoing cutting in alternate seasons. This latter is a capital way of imparting strength to weak beds. Unfortunately, it is only where there are few Asparagus beds that weak produces predominates. I leave young beds alone for two or three years after planting, so as to enable the plants to gain strength, and the principle holds good with other beds. Upon looking over beds when cutting has not long commenced, it is no frequent occurrence to see young and weakly

shoots growing ahead, the reason given by those who are responsible for the cutting being that they are left to give strength to the roots, as, being weak, they are not fit for cutting, and are left accordingly. This is certainly a very erroneous opinion. Leaving the smaller growths prevents others from pushing up, and instead of the weak stems gaining strength they do not add to this in the least. The best course is to cut all as they appear until the time arrives to cease cutting, and then to allow all to grow ahead. Certainly, if there are any weak crowns, then these should have been marked and left uncut until they are in a sufficiently strong state to bear the strain. Whether the principal part of the stems is required

BLANCHED OR NOT is a matter of taste, but as a rule the non-blanching stems find the most favour. But whether the stems are needed blanching or not, some people when cutting appear to think that it is part of the routine to cut low down into the bed so as to procure the desired length of blanching growth, with the result that if they are not adepts at the work, with the constant wriggling of the knife they damage two or three incipient heads in the process. I dare say it will have been noticed that even if a good length of blanching stem is sent to the kitchen the greater portion is cut off and thrown away. The best way is to move a little of the soil with the knife at the base of the stem, when the length required may be easily removed. Earthing over the crowns above the surface with leaf-soil and sand is certainly the best method for procuring blanching stems. All that is necessary is to place small hillocks of the material over the crowns, and as soon as the tips rise above the surface, the soil can be quickly moved from the base, and the stems cut off level with the surface. The stems also thicken more under the influence of the blanching material.

A.

3800.—**Cutting Asparagus.**—No, decidedly not. Do not cut off the small growth; allow it to grow as freely as possible. After the last pieces are cut from the bed early in June, give the bed copious supplies of liquid manure to induce as free a growth as possible being made. Failing liquid manure, sprinkle dissolved bones over the soil, and water the beds with clear water. Just a covering with manure will be sufficient. It is a good plan to support the Grass on the beds when it has become developed in some way or other to prevent injury from wind. Thrust a few short Pea-stakes in amongst the plants; this prevents their awaying about, and saves the roots from being broken.

—S. P.

—Cut off all the small growth so long as cutting continues. If the small shoots are allowed to grow they will, of course, get stronger, but it will be at the expense of the stronger crowns. When everything is cut till the end of June, and the whole then allowed to come away together, the strong growths will keep down the small spray, which is really of no use.—E. H.

3834.—**Japanese! "Cucumber."**—The statement that this Cucumber is very hardy and that it can be grown like Scarlet Runners must be received with caution, as I do not know anyone who grows it in this country. I am doing so for the first time, and although the plants thrive rapidly under glass, they have a tender look about them, which does not impress one of their capacity to adapt themselves for open-air culture in England. I shall, however, turn some plants out-of-doors shortly to give them a fair trial.—J. C. C.

CHRYSANTHEMUMS.

3744.—**Bone-meal for Chrysanthemums.**—This is excellent for mixing with the potting-soil for Chrysanthemum, but it must be of powdered bones, not the shavings from "vegetable ivory," a material sometimes sold for horticultural purposes instead of bones, but it is always useless, and may often be injurious. Good bone-dust, which can be obtained at 9s. or 10s. per cwt., is the cheapest and best manure for Vines, Chrysanthemums, and many other garden crops. I use it with decayed stable-manure as follows: Three parts good loam, one part leaf-mould, one part decayed manure, and a 7-inch portion of the powdered bones to each barrel-load of the mixture.—J. D. E.

3833.—**Early Chrysanthemums.**—I have placed the varieties in their order of

flowering as near as possible. The treatment the plants receive may make a difference to some sorts. Fernand Feral, Stenstead Surprise, Jeanne d'Arc, Lord Wolseley, Novelty, Lady Churchill (single), Acquisition, Puritan, Comtesse de Beuregard, Mons. J. M. Pigmy, Lord Alcester, Cloth of Gold, the Three Christines, Jardin des Plantes, Violet Tomlin, Etelle de Lyon, and Thunberg. For cutting down those numbered thus—1, 3, 4, 8, 9, 14, 15, and 16, are the most suitable varieties.—E. M.

ORCHIDS.

LADY'S SLIPPERS.

Of all the Lady's Slippers, *Cypripedium Manleyi* is, I think, one of the best. It is simply a form of the old greenhouse kind, *C. Insigne* (here figured), but then it is the best form, and far more beautiful in leafage and blossom than that well-known kind. The white upper sepal, with its exquisite mauve-purple blotches, is very attractive, and in a cool, airy house each individual flower endures quite fresh for a month or even six weeks. Anent *C. Insigne* and its forms, named and otherwise, it is interesting to know that they grow and bloom better in a cool, airy atmosphere during the summer and autumn months than when grown in a close, high, and moist temperature. Some slight shading from the direct glare of sunshine, and a skiff with the syringe morning and evening, keep them clean, and encourage the flowering growths. Some use peat, but charcoal and living Sphagnum is a safe and satisfactory compost for this and many other kinds. B.

DENDROBIUM DENSI-FLORUM.

I AM asked by "C. H." to give him the full particulars of the management of this old species? Now this plant has been introduced upwards of sixty years. It is found in various places in India, mostly in the Northern part, growing at about 2,000 to 3,000 feet elevation, and a good variety of it well deserves the warmest encomium. *Dendrobium densiflorum* belongs to the section called *Calostachya*. These plants mostly produce their flowers in long racemes, and it is a very good type of the section, which includes, amongst others, *D. thyrsoiflorum*, *D. Farneri*, *D. suavissimum*, *D. ohyrantoxum*, and *D. Palpebræ*, and all have about the same character—i.e., that, beautiful as are the flowers, they are somewhat short lived, and do not remain long in beauty. It is an evergreen plant, retaining its leathery leaves for several years. The bulbs grow to a foot or more in height, and it is from the top of this growth between the leaves that the dense spikes appear, and it is a species which sometimes would put the annual pruner of bulbs to the right-about, for depend upon it, the grower that has the greatest number of old bulbs left upon his plants which have not flowered will always stand the best chance of having the greatest show of flowers upon his plants. Sometimes these bulbs continue to develop flower-buds long after the leaves have been shed; they usually bloom about this time of the year, or a little earlier, and they last about five days or a week in their prime, but care must be exercised with them when in flower to make them last as long as possible, as the very dense spikes, with its deep-rich orange-coloured flowers, are very conspicuous and showy, and they may be kept upon the plant as long as presentable without any harm to it. There is a very curious thing about the lasting of *Dendrobium* flowers, for the blooms of *D. Deari* will last for as many months as *D. densiflorum* will days, and this is a fact which I cannot find a solution for, but I should like to be able to

explain it. This plant should be potted in well-drained pots, using for soil good peat-fibre and chopped Sphagnum Moss in about equal parts, using in the soil an occasional lump of sharp sand. Pot the plants a little above the soil, and during the summer time the plants should stand in a nice genial East Indian temperature, but in the winter they should be kept in a house in which the temperature seldom or never falls below about 60 degs. during this time; although they should be kept very much drier, they should not be allowed to suffer from want of water. MATT. BRAMBLE.

ODONTOLOSSUM REICHENHEIMI.

THIS species I have received from "A. L.," and I am very sorry to hear the complaint of neglect in not answering the previous communication; indeed, I do not remember ever having seen it, but I will do all in my power to meet the wishes expressed in this last. The name of the flower is given above. This species, like many others, is very variable in its characters—indeed, so

Cypripedium Insigne.

much so that the name is swamped by some authors in the name of *O. levei*; but "A. L." sends the flower which is fairly represented to be this plant, whilst the plant known as *O. levei* is smaller, and much less distinctly marked. *Odontoglossum Reichenheimi* is a strong-growing plant, producing a fine spike of bloom, which lasts long in perfection. In the case of my correspondent, he says the plant had eleven flowers on the spike, and it has been in flower two months. Now the number of flowers mentioned is small, as I have seen some two dozen and thirty blooms open on the same spikes together, and "A. L." may look forward to seeing his producing as many when the plant becomes stronger, and this can only be gained by proper treatment. The plant is a native of Mexico, where it grows upon the Oak-trees, which are very abundant on the mountains about Michoacan. It is a plant which has a somewhat wide distribution in that country, always being found at an elevation between 7,000 (Seven) and 8,000 feet, so that it requires a cool house to be successful in its cultivation, but care must be taken not to let the plant get

dry at any time in the year. Many people used to dry this plant in the winter, and its large and stout growths and-bulbs gave them a plea for so doing; but I have come to regard this as a wrong standard by which to measure plants, and I have found that many of the plants which have the largest bulbs require the most water and watching through the dry season, and it has been my experience with the plant now in question, and if the plant is allowed to shrivel there is sure to be a weakening of the growth the following season. Therefore, let the pot for its reception be thoroughly drained, and using for soil the fibre from good brown nland peat, with about an equal part of good Irish Sphagnum Moss, chopped up moderately small, so that it may mix with the soil the better. When growing during the summer months, the plants should be well supplied with water, and a good moist atmosphere should be maintained, and the same, but in a less degree, during the winter, keeping the temperature at about 48 degs. MATT. BRAMBLE.

A SELECTION OF ANNUALS.

MANY owners of gardens do not grow annuals from the impression that they are weedy looking, and very brief in their duration of flowering, but this is entirely owing to making a poor selection from the long lists published. The following annuals are all reliable, and under good cultivation cannot fail to please—viz.,

ANTERS (*Chias*), in great variety, of which the best known types are the Victoria, Quilled, Globe-flowered, Peony-flowered, and Bouquet; these should be sown in boxes or pots in March, and grown on in a cold-house or frame, pricking them out as soon as large enough into other boxes, and gradually hardening them off, until by the middle of May they will be fine, sturdy plants, which make a fine display in beds or borders, and either for effect in the beds, or as cut flowers, there are few plants to equal them.

CANDYTUFTS, white, purple, and crimson, are very effective in large clumps in the mixed borders, sown where they are to flower; the colours are decided and striking.

CHRYSANTHEMUM CORONARIUM is one of the most continuous flowering plants we have, and makes an excellent background plant for mixed borders, or for beds for either effect or for cut flowers.

CAILLARDIAS, in several varieties, of which *G. plecta*, *G. Loreoziana*, and *G. grandiflora* are the best, are very beautiful and continuous flowering plants; the colours are very rich and varied, and totally distinct from any other flower in cultivation. I sow in heat in February, and grow the seedlings on in a cold frame until May, when they are planted out with other bedding plants, and flower continuously until late in autumn.

LINUM GRANDIFLORUM (the Flax-flower) is one of the best to sow where it is to flower, being quite hardy, and very little trouble. Sown in beds, clumps, or as edgings, it makes a fine display of brilliant colours.

LOBELIA SPECIOSA is probably the best of all dwarf edging plants that can be raised from seed. Sown under glass in February, and prick out in boxes as soon as large enough, and pinch out the points to ensure a dwarf, bushy growth that will flower profusely when planted out in May.

MARGOLDS are very useful plants, especially in dry soils, as they withstand drought, and flower most continuously the whole season. The dwarf French is excellent for edgings, and the taller African variety for backgrounds.

MIGNONETTE is indispensable in even the smallest garden. Sown it well by thoroughly preparing the site, and sowing seed thinly in March where it is to flower. "Machet," "Crimson Giant," and "Golden Queen" are very superior sorts.

NASTURTIUMS, especially the dwarf kinds, are very effective "bedders," if the seed-pods are kept picked closely.

STOCKS, Ten-week especially, are splendid plants, if only you get a good strain, and grow them well. Sow the seed in boxes under glass, and when large enough harden off and plant out in May. They make perfect pyramids of bloom.

SWEET SULTAN has lately become very popular as a cut flower, its beautiful feathery bloom being very effective. It may be had in several distinct colours, and can be sown either where it is to flower, or else sow it in boxes and transplant as soon as the plants are large enough to handle. J. GROOM, Gosport.

FRUIT.

FORCED FIGS FOR MARKET.

If one fruit is more a luxury than another, it is the Fig in a forced state, and few that come into Covent-garden are so liable to sudden fluctuations as regards marketable value. Unlike the Grapes and some other fruits, there can scarcely be said to be any steady demand for early Figs, so that comparatively few growers make a feature of them. Sometimes, when the season happens to be more than usually brisk, Figs fetch long prices; at other times they are a drug, scarcely to be got rid of. Happening to be one day in a fruiterer's establishment in the centre row when a box of Figs came in, the proprietor remarked: "What a pity that these did not come in yesterday! They were wanted, and I could have allowed a good price for them; to-day there is no demand for Figs." Later on

Fig "Black Bordeaux."

in the day I was informed that they were sold for just half of what they would have realised the day before. This is a fair illustration of how wonderfully the price obtainable for this fruit may vary, even in the course of a few hours. I should not advise that Figs be grown in pots for profit; the labour involved would be, I think, too great; but, planted out, they no doubt pay very well, taking one season with another. A successful grower of early Figs for market has them planted out in a open-roofed house, the roots having the choice of an inside and outside border. The trees are trained to the roof, or, rather, to a trellis some 12 inches from it, and the fruit thus grown is good and handsome. In France, more especially in the neighbourhood of Paris, Figs are forced to a considerable extent, for this fruit appears to be more popular the other side of the Channel than with us. The method there followed is much the same as above detailed, but the roof is generally formed of lights, which are removed during a portion of the summer in order to thoroughly harden the wood. The Black Bordeaux Fig (here figured) is a popular early market fruit. B.

STRAWBERRIES FOR EARLY FORCING.

DURING the last few years we have had several new kinds that when put on the market were to eclipse all others, but so far they have not made much progress in ousting well-known kinds. Noble I gave up after two trials, as fully one-half of the fruit did not set and the other was abortive, only a small percentage finishing, these being deficient in colour. For later use it is excellent when brought on slowly in cold frames. This treatment improves the flavour, and the colour is also good. La Grosse Noirée is an excellent variety in every way, but one that I cannot advise for fruiting in February or March. With me it will not throw its trusses sufficiently high enough, and the flowers will not part with the calyx, though brought on slowly and grown in a slight bottom-heat. My reason for mentioning this circumstance is that in some nurserymen's fruit catalogues I have found La Grosse Noirée described as the best for earliest forcing. For later work to come in in April, it is one of the best varieties we have. I gave John Buckle a trial last season, but it failed to produce fruit

up to the advertised quality or in quantity. King of the Earlies is a miserable small fruit not worth attention if grown by the side of Vicomtesse Hérolet de Thury, this in my estimation being the best Strawberry for early forcing. I have given Pauline a trial; it certainly is early, but its shape condemns it, and I cannot advise it for pot-work. I have a hotter opinion of Competitor, but would prefer to give it another trial. I am pleased with its colour and flavour if it sets freely when hard forced. I do not think we have yet found a Strawberry to equal Vicomtesse for early forcing, and my note refers to fruits ripened in February or March. To follow this, Keens' Seedling will not be easily beaten. It is an easy matter to get fine fruit of forced Strawberries in May, as when the difficulty of setting is taken into consideration, there is not so much merit as when a fair dish of Vicomtesse or any other is shown two or three months earlier. Another point is that many gardeners

cannot devote much room to the plants, so that Strawberry forcing is carried on under great difficulties. One great advantage in growing Vicomtesse for early work is the way it finishes in small pots. It will also do in a moist house, and is less subject to insect pests than some kinds. It would be interesting to know if large growers succeed well with these new kinds. So far as I have seen, very few of them appear in the market till April comes in, some even later, so that I see little merit in them, as we have plenty of good kinds that come in at that period with ordinary forcing. G.

SUMMER PRUNING OF FRUIT-TREES.

THE exceptionally brilliant weather we have had all through March and April has had a very marked effect on vegetation generally, and on fruit-trees and bushes in particular, the growth being already quite a month in advance of last year. Under these conditions it would be unwise to stick too closely to dates for any given operations, as exceptional seasons call for exceptional means to cope with them, and what is called summer pruning will need attention in advance of what we ordinarily call summer dates. I am aware that great differences of opinion prevail as to pruning, but so long as fruit-trees are grown as artificially-trained trees so long will the necessity for pruning remain. Taking wall-trees as the most favourably situated for early growth, we find the following needing attention:—

APRICOTS, of which the crop is generally good, need hand-picking of all curled leaves, and pinching of the shoots not needed to be trained in for another year. Hard pruning is decidedly injurious, but allowing the shoots to grow entirely unchecked is far worse loss of force needed to swell the crop.

PEACHES and NECTARINES need great care in the early stages of growth. Once get them evenly covered with clean, healthy foliage and little difficulty is experienced the rest of the year; but when entering into growth they need looking over at least twice a week, picking off all shoots that are not needed, and blighted and blighted leaves, dusting with sulphur if mildew appears, or syringing with Tobacco-water if black-fly gets into the leaves.

PLUMS and CHERRIES are not usually so difficult to manage as the preceding, but they grow very rapidly at this time of year, and the fore-right shoots need shortening, and all that are needed as leaders or for filling bare spaces should be lightly fastened to the walls or trellises. Syringe heavily to wash off all old blights and keep down red-spider.

PEARS on walls and trellises are growing very fast, although heavily cropped. Shoots not needed for extension should be pinched to about half-a-dozen leaves. I usually thin out fruits and shoots at the same time, as it can best be done by degrees, taking off the worst placed fruits and shoots until both crop and shoots are reduced to what are needed to remain.

APPLES, being late in starting into growth, do not need early attention in the matter of pruning; but in common with other trees they are exceptionally forward for the period of the year, and pinching of the points of shoots that crowd or shade the fruit should be done at once. Seldom has such a crop been seen as there is set this year, and more attention should be given to all the details of culture to help the trees to perfect the crop.

VINES on open walls are more frequently rendered barren for want of timely attention to summer pruning than any other cause. Directly the shoots are long enough to discern which are the ones to retain, thin them out at once, and pinch the points of those left on joints beyond the bunch. If half the attention lavished on Vines under glass were bestowed on open-air ones, very decent crops would be the rule, instead of the exception.

BUSH-FRUIT, especially Currants, are greatly benefited by having the points of the shoots pinched out as soon as they have made half-a-dozen leaves. Try it this year, and you will make it an annual custom afterwards. The fruit will be finer, and next year's wood fuller of fruit-buds than if left unpruned.

J. O., Gosport.

3826.—Barren Strawberries.—Probably the soil is "sick" of this particular crop. You should make a new bed in a fresh place, planting runners obtained from a fruitful bed elsewhere. It will be worse than useless to propagate the barren plants. A good dressing of burnt earth and a little lime might enable the old bed to grow fruitful plants; but the safest and best way will be to give a change of ground.—B. C. R.

Occasionally a few Strawberry plants in a bed will become barren, and these, owing to their not having to bear the weight of fruit, produce the earliest and best runners; inexperienced cultivators take the runners from the barren plants, and all such runners are likely to produce barren plants again. Whenever a barren plant is found in a bed of Strawberries it is much better to dig it out. It is no good as a fruit-bearer, and deceptive as a breeder of runners. If this is constantly practised barren Strawberry plants will soon disappear from the garden. The treatment of the plants was such as should have produced good results.—J. D. F.

Strawberries should have a change of land for every fresh set of plants. Planting one crop after another on the same land may not be the cause of barrenness, but it is bad culture, and might lead to it.—E. H.

3822.—Treatment of a Pear-tree.—From the information contained in this query I am led to believe that the roots require pruning to check green growth, although at the present time it is nothing unusual for the new shoots to be 15 inches long. Some Pear-trees do not give annual crops of fruit, neither do they blossom freely every year. The young shoots ought to be shortened back, as they grow to about 4 inches of the base, to admit of the spurs receiving light and air, with a view to maturing the wood in the autumn. At the end of September a trench should be cut around the tree 3 feet away from the stem if it is under ten years old, severing all roots that are met with. If the tree is older, 1 foot more will be necessary.—S. P.

This is a case where root-pruning may have done good. The tree is evidently over-vigorous, and forms strong young wood instead of blossom buds. If the shoots are cut off now a more numerous family of them will be produced in the place of those that have been

removed. It is not stated whether the tree is a standard or a dwarf, or it may be an espalier, and perhaps a wall tree. If it is an espalier or a wall tree it must be cut in well annually, but if it is a standard or dwarf the best way to throw it into blossom is to allow the young wood to develop considerably, merely thin it out where too thickly placed and cut the points out of the young shoots. If the tree is an espalier or a wall tree it ought to be root-pruned in November.—J. D. E.

— The tree is getting a little out of hand, but there is nothing you can do now. Early in October root prune half round the tree, and watch the result. Perhaps the other half may not require to be pruned for two or three years.—E. H.

3833.—**Vines bleeding.**—I cannot tell you how to stop this. I have known many attempt to do so, but always failed. You need not get anxious about your Vines, as they are not likely to be any the worse for it—at the same time it is not desirable that they should behave in this way. Another year prune a month earlier, and keep the Vines cool. No Vines ought to be subjected to a higher temperature than 45 degs. directly after they are pruned. The bleeding will probably continue—only in a lesser degree—for several weeks longer.—J. G. C.

— It is very rare for a Vine to bleed after the leaves expand, and therefore I conclude the bleeding is now stopped. In future apply the styptic at the time of pruning before the sap rises.—E. H.

3753.—**Vinery.**—Forty feet is rather wide even for a large and lofty vinery, and perhaps it would be better to erect a double span-roofed house, covering the whole of the ground. Each house, or span, would thus be 20 feet in width, and the side walls should be 3 feet high, with (preferably) 3 feet of glass above that, which will bring the upper plate, or eaves, 6 feet from the ground, and the height from floor to ridge should be 14 feet or 15 feet. Provide plenty of ventilators along the ridge (on both sides), and every alternate light, at least along the sides, should also be made to open. Unless you want one house to come in after the other the cheapest plan will be to build the two outside walls only (of good 9-inch work, of course), and support the central ridge plank (which must be at least 18 inches wide, and proportionately thick, with a piece of 5-inch by 3-inch quartering bolted along each edge of the upper side, so as to form a gutter), on substantial brick pillars, 5 feet or 8 feet apart. But if a different temperature has to be maintained in each house there must be a divisional wall, of course. Artificial heat is not actually necessary, at least if Black Hamburghs, &c., stons are to be grown, but a couple of rows of 4-inch piping on each side will be found a great advantage, and some heat is absolutely necessary for Muscats, &c., or if the Vines are to be forced. Plant the Vines in February or March, when starting, at 2½ feet apart, if to be grown on the single-rod system.—B. C. R.

3830.—**Strawberries for market.**—I have known the plants die away as described, but I believe it is a very uncommon occurrence. Some very light soils do not suit Strawberries, and if your soil is of this description you will find Black Prince, President, Garibaldi, Eleanor, or John Powell succeed better than Paxton's, "Queens," &c. I should also recommend you to try the effect of a dressing of burnt earth, soot, and a little lime on the parts of the ground where the disease appears. In my experience the best substitutes for stable-manure for this crop is Thomson's Vine and Plant manure.—B. C. R.

3824.—**Stopping Melons.**—As a rule, the fruit forms on the young shoots at the second joint from the base where they push from. In some instances, though, they form at the first. It is not advisable to stop the shoots until the fruit has been fertilised a day or two, except it can be done before the fertilisation takes place, for fear of the lateral getting too long and overcrowding its neighbour.—S. P.

— These in all good gardens are now trained to a trellis, so that the operator when attending to the plants works underneath them. The best way to treat them is to allow the leading shoot of each plant to run half way up the trellis. Stop the leading growth there, and laterals will be abundantly produced. Stopping a shoot immediately the blossom is fertilised might cause the fruit to drop off. When it is

seen the pollen has taken, stop the shoot at once two leaves beyond the fruit. In setting Melons, it is very desirable to wait until as many female blossoms are open as it is intended the plant should carry fruit, and set them all as nearly as possible together.—J. D. E.

— I usually stop the laterals of Melons, when a couple of leaves have been made. The object of stopping is concentration. But when a leaf or two is left, there is always a force at work beyond the fruit to carry on the circulation, and this, I think, is what is required. A Melon may have been operated upon without being fertilised. As cultivation has a good deal to do with Melons setting, or otherwise, Melons growing in a firm bed of good loam will usually set their fruit better than if grown in lighter, looser soil.—E. H.

— No, it is not advisable to stop the lateral growth of Melons directly the flowers have been fertilised, for the simple reason that unless the plants are grown in a house on the extension system the laterals do not extend after the fruit once begins to swell. If the growth is stopped at, say, the third joint beyond the fruit, it is not unusual for the leaves to die away gradually. The fruit, it appears, monopolises all the strength of the shoots, and as a consequence the leaves diminish in size, and when this is the case indifferent flavoured fruit is the result. It is an interesting question, as "Brightspade" remarks, but it is one of those matters that can only be dealt with by the condition of the plants to be operated upon. If they are weak, depend upon it, it is a mistake to stop the laterals intended to produce fruit. It must be remembered that the flavour of Melons depends entirely on the quantity and health of the foliage. If there are but few healthy leaves the flavour is only second rate, and by preventing the laterals from forming fresh leaves we run the risk of injuring the flavour of the fruit.—J. C. C.

3836.—**Strawberries and Clover.**—This is not the first time that this subject has been mentioned, and I remember seeing it definitely stated that the decaying roots of Clover act as a fertiliser to some crops while of no benefit to others. I have had no personal experience of this matter, but I hope those who are possessed of chemical knowledge will enlighten us on this matter.—J. C. C.

3835.—**Grapes, &c., for very early forcing.**—The best of all Grapes for very early forcing is undoubtedly Black Hamburgh. If you wish to have Grapes ripe in May or June, you could not do better than plant the whole house with that variety. White Grapes are not nearly so profitable early in the year as black. Foster's Seedling is the best white for early forcing. Muscat of Alexandria, of course, is the finest white Grape in cultivation, but, of course, not to grow with Black Hamburgh nor to be ripe before July. In an early house it is a mis-

might grow early! Potatoes in 10-inch pots, or you might force Mint in boxes. There is always a demand for this Herb early in the year. Strawberries can be grown along with the Vines if you have shalvee put up close to the glass so that the plants will have sufficient light at all times. Great care in watering, however, is necessary to prevent the leaves being attacked with red-spider.—S. P.

— Two of the best Grapes for very early forcing are Black Hamburgh and Foster's Seedling; Madresfield Court and Buckland Sweet-water also force well. It is not impossible to grow Cucumbers between Grape-Vines when the latter are young and do not require all the space; but Tomatoes would do better, as Cucumbers require more shade and moisture than would be good for the Vines. Still, an early fruit or two may be had from Cucumber-plants in large pots or tubs in a vinery. French Beans also will do very well for a time if there is heat enough; but French Beans will not do much good in a lower temperature than 60 degs. The produce of a small house 20 feet long should be disposed of locally, as it would not pay to send long distances.—E. H.

THE ANDROSACES.

THESE are, perhaps, the most alpine of alpine plants. Other families send down representatives to the hill pastures or the sea rocks, or sunny becks, as the Primroses and Hairballs do, but not so these. They are more alpine even than the Gentians; for, as we have seen, the Gentians are as handsome in a hill meadow as on the highest slopes, and as Androsaces are, among flowering plants, those most confined to the snowy region, so, as might be expected, they are the dwarfest of this class. They belong to the Primrose family, and resemble it in its flowers, but even dwarf alpine Primroses are giants to these, which, from their extreme dwarfness and compactness, might be called, for an English name, lowering Mosses. Growing at such great elevations, where the snow falls very early in autumn, they flower as soon as the snow melts. Sometimes, like some other alpine flowers, they frequent high cliffs with a vertical face, or with portions of the face receding here and there into shallow recesses. Here they must endure intense cold—cold which would probably destroy all shrub or tree-life exposed to it. And here in spring they flower. Thus, in crossing some passes on foot in spring or early summer, while all the hills around are a waste of snow, the traveller has the pleasure of seeing these charming fairies in full bloom. Generally, however, they have to wait till the snow disappears, and then, in every high spot, one sees the ground silvered with their cushions and gay with their modest little flowers of white, or rose, or yellow. As yet far from common in our gardens, it is, nevertheless, the aim of every

Androsaco lanuginosa. (See page 182.)

take to plant many varieties—in fact, it is in any house; the more the sorts are kept together the better is the prospect of success. French Beans in pots may be grown very well under the Vines. The best variety is Sutton's New Forcing. Sow five Beans in a 3½-inch pot. When they show the first rough leaf shift them on into 8-inch pots without disturbing the roots. Any light rich soil will suffice. They must never be allowed to become dry at the roots or red-spider will attack the leaves and this is sure to travel from there to the Vines. You

lover of alpine flowers to possess them in good health. This is not difficult where there is a properly formed rock garden in a pure air. They are among the plants that are almost sure to perish in a smoky atmosphere. Their small evergreen leaves, often downy, retain much more heat and soot than smoother and larger-leaved evergreen alpine plants do. The Androsaces enjoy in cultivation small fissures between rocks or stones, firmly packed with pure sandy peat, or very sandy or gritty loam, not less than 15 inches deep. They should be so placed that

no wet can gather or lie about them, and they should be so planted in between rocks or stones that, once well-rooted into the deep earth—all the better if mingled with pieces of broken sandstone—they could never suffer from drought. It is easy to arrange rocks and soil so that, once the mass below is thoroughly moistened, an ordinary drought can have little effect in drying it. A *Laegioea* (illustrated on page 181) is distinguished by its spreading and sometimes, when in a vigorous condition, long trailing shoots, and bearing umbels of flowers of a delicate rose, the leaves being covered with silky hairs. In very cold districts it should be preserved during winter in a dry pit. V.

HALF-HARDY ANNUALS IN POTS.

THESE supply us with a lot of most useful material for conservatory and greenhouse decoration, particularly during the summer and autumn months. Being in most instances of comparatively easy culture, they may be relied upon as a good source of supply when there is insufficient room to grow plants of a more permanent character. Prominent amongst these annuals are the *Rhodanthes*, which for flowering in 6-inch pots from May onwards are most desirable, lasting such a long time in good condition. It is now too late to sow for early flowering, but seed now sown will provide a stock of plants to flower early in July. The soil for *Rhodanthes* should be made firm, as in the case of *Mignonette*, no further potting being required. It should be raised in a slight heat, not by any means too warm, so as to produce a weakly growth. A shelf in ainery just started would do well, shading the pots until the seed is seen to be germinating. When a good start has been made a cooler house will be better, the vinery meanwhile rising too rapidly. Water carefully until the pots are tolerably well filled with roots. When the plants are showing flower a cold pit or frame will suit them very well if room in the greenhouse is short. Another annual of this class that gives a good return, flowering continuously for many weeks, is *Alouosa Warscewiczii* compacta; its bright scarlet flowers are not at all unlike those of a *Chorezema* when seen at a distance. This *Alouosa* will thrive well under the same treatment as advised for *Rhodanthes*. The *Amaranthuses*, as represented by *A. bicolor*, *A. tricolor*, and *A. melancholicus ruber*, supply a class of plants that are not so often seen in pots as they deserve to be. Their value lies, of course, in the foliage effect produced. They require rather more warmth than either of the foregoing, with more moisture until well established; by that time a cool house or pit will suit them well if guarded against any excessive draught. *Balsama* hardly require more than an allusion; they are not, however, seen in nearly so good form as their merit justify. It is a mistake to sow the seed too soon. This is often done; hence the plants become too large before there is room to accommodate them after the bedding plants are disposed of. When sown in April or May a cooler course of treatment will be safe, resulting in more sturdy plants that will do a good turn in July and August.

BROWALLIA ELATA GRANDIFLORA is a very useful annual for the summer and autumn, lasting a long time in flower, at the same time supplying a colour none too plentiful. The plants do best in a gentle warmth until well established in their flowering-pots. By sowing in pans, pricking off into 3-inch or 4-inch pots, three or five plants in a pot, and then shifting into 6-inch or 8-inch pots, and pinching once or twice, nice bushy plants will result. When a large stock and variety of plants are essential in August and September, it is well to grow some of the best strains of *Heliclysum* in pots. These, if raised in the usual manner as for planting out-of-doors later on, will, if retained in pots, make very useful material for a large conservatory. Until well established, it is best to keep them in a cold frame; then they can be plunged in an ash bed to receive one more shift later on when in need of it. Being gross feeders, these plants will take a liberal supply of manure-water when the pots are well filled with roots. *Lobelia gracilis* should have a place in the most limited collections, either for hanging baskets or to arrange along the margin of

stages, over the sides of which the drooping branches will hang in a most graceful manner. For hedging this kind is not of so much use, except it be as a carpeting to tall plants or for rustic vases or baskets, but when applied to porpoese suitable to its habit of growth, it is a most beautiful plant. *Nicotiana affinis* should not on any account be omitted; it is not necessary to grow a quantity of plants, it is true, for a few even will emit a delicious perfume during the latter part of the day and in the evening. It is easily grown, and until in flower, may be kept out-of-doors after being well rooted and fairly started into a robust growth. The compact growing types of *Petuisias*, both single and double, should have due consideration treated as for bedding out, but retained in pots they will be found useful after a few pinchings to increase the number of shoots. These will come into flower after the *Pelargoniums* have ceased to be effective towards the end of June or beginning of July. The

SALPIGOLISSIS, particularly the dwarf strains, will prove of considerable service for autumn flowering in conjunction with the *Heliclysums*, and may be grown under the same treatment. *Schizanthus retusus* and the *var. albus* and *Grahami* make fine plants for the conservatory in the spring if sown later in the year, whilst if sown now they will flower in the autumn, lasting until the *Chrysanthemum* turn in. This is a half-hardy annual that should be more grown than it is where much flower has to be provided, or where easily cultivated plants are more essential. Ten-week Stocks are almost indispensable; they may be had during a prolonged season by sowing at intervals. The earliest sown seed will soon be making flowering plants, but a sowing now made will provide a supply for the summer, and one or more later on will form a good succession in the autumn. For extra early flowering in pots the intermediates are the best, these being kept through the winter in a cold frame. The common mistake made with Stocks in pots is that of supplying them with too much water in the earlier stages of growth. No anxiety need be entertained as to their recovering their freshness after having been potted off; this they will quickly do without the aid of frequent dampings overhead. This attention in many cases would be beneficial; with Stocks it is otherwise. With half-hardy annuals it is most essential—as in the case of all annuals, in fact—not to overcrowd the plants in their earlier stages of growth in the seed-pans. A good start made with dwarf stocky plants will go a long way towards ensuring success. Such plants have every advantage compared with those of a weakly and spindly growth, the result of either sowing the seed too thickly or through deferring the first pricking off or thinning out, as the case may be, until it is almost too late to perform it. Too much warmth in the earliest stages is equally injurious, and eventually fatal if persisted in. Light is an all-important factor in developing a substantial growth; so also is free ventilation when the plants are fairly well started on their course. As soon as the plants cease to be of any use they can be thrown away to make room for those of a permanent character before frost sets in. II.

TREES AND SHRUBS.

PLANTING CLIMBERS IN MIXTURE.

THE utility and interest of planting climbers in mixture are not as often taken advantage of as might be the case. The gable ends of my cottage are fully garnished with *Virginian Creeper*, *Aristolochias*, *Jessamines*, *Clematis*, *Honey-suckles*, *Ivies*, *Tea Roses*, notably *Reine d'Or* and *Gloire du Dijon*, grown and trained in delightful mixture: while a massive chimney, clothed with broad green *Ivy* (*Ragneriana*) as a groundwork, *Aristolochia Siphon*, the chaste *Clematis Standishi*, white *Jessamine*, *Lonicera aureo-reticulata*, *Virginian Creeper*, and *Rose Reine d'Or* have thoroughly covered to the very top, and compete with each other as to which can produce the greatest charm, while the lower part of the cottage wall all around is furnished with still greater and additional variety. *Barberis Barvini* has attained the height of 15 feet of late, and I hope to see it yet gain the top. *Baccharis macrocarpa*, *Clematis* of the Jack-

mani type, semi-climbing *Roses* of the *La France* type, *Jasminum nudiflorum*, *Chimonanthus fragrans*, *Clinanthus panicula*, *Aloysia citrodora* (*Lemon plant*), together with broad vigorous patches of *Tropaeolum speciosum*, and the rarer, *T. polyphyllum*, *Calyptegia pubescens* fl. pl. *Hops*, &c., are also planted on the wall. A prominent part in this miniature wall decoration is taken by that fine old nearly evergreen *Rose Ophir*, which occupies considerable space on the east wall, and has grown right up to the eaves. By-the-way, this is a *Rose* deserving far more notice and extended cultivation for this purpose than are now accorded it. The benefit of this mode of planting is apparent in the increased and prolonged effectiveness and additional interest given to a wall thus treated, especially where wall room is limited, and as far as I can observe, with a common sense and timely thinning of shoots, &c., none of the subjects employed are much the worse for their associates. Of course, to keep up the vigour of such a medley crowd, their order must on no account be overlooked, but be kept freely and often supplied with substantial and invigorating fare. One more word as bearing on this double planting, or whatever it may be termed, as applied to shrubs as well as climbers. A pleasing little feature attached to this same cottage is a small shrubby thinly planted chiefly with spring-flowering shrubs to hide the back premises. This is overrun with pink *Convolvulus* and *Hops*, which make a splendid autumn display, long flowering shoots, twining and festooning over and from shrub to shrub, covering the whole with a mantle of beauty. J.

3816.—**Thuja Lobbi.**—The first week in April is the best month to plant this shrub, especially if a little attention can be given to them during the summer in the way of watering occasionally and mulching the surface with 2 inches of partly-decayed manure. The ground ought to be trampled deeply in the autumn, adding a little manure to the soil just under the surface. If possible, cover the roots when planting with a little decayed vegetable refuse or old potting soil. This may seem unnecessary, but any little attention like this is time well spent, the trees make so much better progress afterwards. This *Thuja* is not at all particular as to position. £5 per 100 would be a fair price to pay for trees 18 inches high, a good size for hedge planting.—S. P.

This Conifer is not expensive, and you could plant it in early autumn with every prospect of the shrub succeeding well; and the soil must be moderately light. *T. Lobbi* is one of the most popular of its class, and makes good progress in ordinary gardens, but, like the majority of Conifers, does not like the neighbourhood of large towns. The miserable aspect of the shrubs in town gardens does not impress one with their usefulness for such positions—in truth, in small gardens especially, the planting of Conifers has been quite overdone.—C. T.

The cost varies according to the work done in transplanting. In the nurseries where the plants are permitted to grow without root disturbance they can be bought much cheaper than where regularly lifted, but the untransplanted trees would certainly die in a season like the present, and some of them would die under any circumstances; therefore price is no criterion of quality. *Thuja Lobbi* is sometimes confounded with *Thuja gigantea*, and the last-named is more valuable than the trees sometimes sold as *T. Lobbi*. *T. gigantea* is comparatively scarce and dear, but good plants can be purchased for about 2s. 6d. each and upwards, according to size. They will move very well in early autumn. It is a very hardy tree and will grow anywhere.—E. H.

3741.—**Clethra arborea.**—This is an evergreen, with white flowers in September. It should be potted in the spring, when the new growth is commencing, using good sandy peat and draining the pots well, and making the soil quite firm. During the season of growth rather liberal supplies of water are necessary, and even in the winter the soil ought never to become really dry. The plant should have a light and airy position at all times.—B. C. R.

3814.—**Fruits of Chimonanthus fragrans.**—There is nothing unusual in this tree setting some of its flowers and producing seed.

Two years ago when thinning out an old specimen on a wall I discovered several pods that had been hanging a year. The seed was sown and grew in a few weeks. At the present time there are a quantity of fruits upon some young plants, and a quantity of seed will doubtless be ripened by next winter.—A. H.

— The recent hot and dry weather, coupled with the favourable site the plant enjoys, will account for the fruiting of this shrub, which is unusual. This is one of the most charming of flowering deciduous shrubs to be met with, but seldom is it seen.—S. P.

— The fruiting of this plant against a main wall is not a rare occurrence—at least, I have often seen the fruit on old trees.—E. H.

— The fruiting of this plant is certainly not a common occurrence, although seeds are occasionally seen on old trees.—J. O. C.

3734.—**Hollies.**—Syringe them well two or three times every day, getting the water well on to the stems and old wood. At the same time keep them nicely moist at the roots. I should say the soil has been too dry. I transplanted some in March, kept them well watered, and they have not lost a leaf. If you can shade from hot sun it will help to keep the wood from shrivelling.—J. C. B.

by the path? They should not be set too near it; if there is space for spare 6 feet or 8 feet will be a good distance for the larger growing ones, putting dwarfier kinds near the path so as to avoid a continuous line. You can fill up vacant spaces with perennial plants and bulbs. Of evergreen shrubs, Hollies, Yews, Boxes, and Aucubas are good reliable kinds. Some people are very fond of Cypress and Thuja, but I do not care for many of these alien looking trees; one or two from their pyramidal shape make a pleasant variety. Of flowering shrubs and trees there is an almost endless choice. I may just mention Pink Hawthorns, Lilacs, Guelder Roses, flowering Currants, and strong growing Roses as suitable. You will not require many in a length of 30 feet, as each tree should have a chance of developing its characteristic beauty. It is very important that the soil should be well prepared by being dug up and enriched if it is poor and exhausted. If the ground at the end of the steps is stoned and not laid with turf, you should try to get it covered with rock plants or such things as the smaller growing Periwinkles and St. John's Wort. If you have rock plants, they will need a few good-sized

soil; this will soon draw out more roots and considerably strengthen the plants. Any stems that may be observed to be too dry should be kept syringed every day, or water may be poured down them from the crown of the fronds. Moss could also be bound round the stems from the soil to the top; if this is done at this time of the year, it will in most cases soon be found out by the roots, as the keeping of it moist is not now so difficult as in very hot weather. This, in the case of some kinds, greatly assists the plants and adds to the vigour of the fronds, as well as to their numbers. It is not, I think, advisable to adopt it in every instance. I would not do so when the growth is already as much as one could desire; in other cases, however, it is a decided help. If pursued from year to year, in the case of young plants the stems increase in height more rapidly. Those which are known to be troubled with scale or thrips should receive every attention now. When the case is a bad one, I would remove the fronds, if they can be conveniently spared, one or two at a time. Syringing or fumigation will destroy the thrips to a great extent, but the scale wants more getting rid of. In doing this, care should be taken that the insects do not fall upon other plants. In a few weeks' time another examination should be made, which will go a long way towards getting clear of them. Cibotium princeps and C. regale should not be kept in too cool a house; they will not bear so cool a temperature as Dicksonia antarctica (here figured) or Cyathea dealbata. C. regale is of the two the hardier. IL.

A fine Tree-Fern (Dicksonia antarctica).

CHOICE FERNS.

CHEILANTHER RADIATA AND OTHERS.

A small frond of this plant comes to hand from a lady, "Miss Jen," asking its name and for some hints as to its cultivation? The name is here given, but it is a plant not well known amongst Fern growers, although it has been in cultivation since 1827. It belongs to the Adiantopsis, established by Fee, but which is now reduced to a section of the above genus by Hooker and Smith. The frond consists of a small one, having only four radiating pinnae, beside the main and terminal one, but I have grown it with six and eight, and measuring 8 inches across; but then the plants were evidently much stronger than the one in question. This is a beautiful Fern, which is widely spread over the West Indian Islands and also in Mexico, Caraccas, and Brazil. Consequently it requires to be grown in the stove, and the pots to be well drained, using as soil two parts peat, nicely chopped up with the spade, and one part good light turfy loam well mixed and made sandy. Water freely, and maintain a nice warm, moist atmosphere, and you will, "Miss Jen," succeed in growing this Fern well. The following are some of the plants belonging to the section Adiantopsis besides the one just mentioned—

C. CAPENSIS: This pretty plant, as its name implies, comes from the Cape of Good Hope, and is somewhat rare in cultivation with us, although it succeeds under a warm greenhouse treatment. When at its best the fronds are nearly a foot in height, and the pinnae or bipinnate of twice divided, with the edges of the segments toothed, the colour being rich bright yellow. C. H. PADATA: This is a rare species which comes from the West Indian Islands, having the stems of an ebony hue. The lower part of the frond at once reminds one of C. radiata, but it grows out of character in the upper part and becomes bipinnate, with the segments quite resembling C. radiata, and for which it might be taken, but in that kind the central pinna, although the largest is always simply pinnate, it requires stove heat. All these species are peculiarly choice kinds, adapted for the culture of a lady Fern fancier, and I should be pleased if the lady signing "Miss Jen" would add them to her collection, and then ask me to see it, for I, like herself, live in the London district. J. J.

3744.—**Shrub seeds from New Zealand.**—Sow the seeds at once in well-drained pots or pans of very sandy peat, with a little loam and leaf-mould. Keep them in the heated house, with shade from sun, and the soil always moderately moist. When up and well in growth, transfer the seedlings singly to small pots, using the same soil. Keep in the house for a time, then remove to the frame, so as to harden them before the winter sets in, and house again the end of September.—B. C. R.

3772.—**Trees, &c., for a garden path.**—I do not think it would be satisfactory to plant trees to meet over the path to the house, or to have climbers trained to form an arcade, though a separate arch here and there might not be amiss. The trees would probably be too large for the place if they met overhead, and creepers if trained as proposed would require much attention, be unpleasantly dripping in wet weather, and, as you say your house is raised much above the path, the view from it would probably be upon the arches rather than through them. Would it not be better to wait till autumn, and then get a nice selection of evergreen and flowering shrubs and set these along

stones to keep up the earth and make little flat beds for them to be set in. Should the space at the end of the steps be left vacant, by all means plant a tree or creeper there. Attention to these little details make a great difference to the appearance of a place.—B. E.

FERNS

TREE FERNS.

THESE, when in small pots or tubs, as compared with the size of the plants, will generally require a good supply of water. On no account should they be allowed to suffer. This may possibly occur at this season of the year sooner than one is aware of. When there is a difficulty in getting sufficient water to penetrate the ball of earth, and the pots are crammed with roots, I have made holes into the soil some 6 inches or more in depth; these will direct the water more towards the central part of the ball if the holes are made in that direction. Young thriving plants will need careful looking after, particularly those which are beginning to make a stem. Some Sphagnum Moss should be tied around these stems close to the

3747.—**Maiden-hair Ferns.**—The best and only safe way to obtain good fresh spores is either to save them yourself (from the well-matured fronds of any old plants) or to get them direct from a good grower of Ferns. They

must be sown on a rather rough surface of fine, silty loam, in extra well-drained pans. Do not sift the soil, or attempt to render the surface very level, but simply crumble the loam in the hand, and moisten it by soaking the pans halfway up in water for about half an hour. Keep them in a shady and "quiet" corner of a rather warm house or pit, with a moist atmosphere, and when necessary dip the pans halfway up in water as before. As soon as the young seedlings (which look like Moss) are well up prick them out into other pans or boxes in little clumps, and when sufficiently advanced divide again, and transplant them singly, finally transferring them to "thumbs." *Adiantum cuneatum* is the best for all ordinary purposes. The winter or early spring is the best time to sow, as at this season Moss is apt to grow and smother the young Fern.—B. C. R.

HARDY CYCLAMENS.

CYCLAMENS *COUM* and *IBERICUM*, as well as the charming little hybrid *Atkinsii*, have bloomed freely in the open air. I had a bed of the latter, containing about a hundred plants, covered with the dainty little blooms, varying in colour from the purest white to rosy-red. I know of nothing more delightful in the early spring days than these hardy Cyclamens, so charming in form and colour. The rich-green of the foliage, which in sheltered situations does not suffer from hard frosts, shows up the flowers to great advantage. *C. vernum* is not so showy as the above mentioned, and rather more delicate of constitution, but very pretty and worthy of careful culture. One of the most fragrant flowers I know is *C. europæum*. This blooms in summer, and does best where it gets shelter from hot sun. The fragrance of this Cyclamen is so powerful that a plant carrying half-a-dozen blooms will perfume a moderate-sized greenhouse. For this reason it is well worth growing in pots. These hardy Cyclamens grow freely in a light compost, consisting mainly of leaf-soil with a little loam and a liberal addition of brick rubble or mortar rubbish. The combs should be buried 3 inches or 4 inches deep, and a cosy neck sheltered from east and north winds should be chosen for them. The autumn-blooming *C. hederacifolium* is a very hardy vigorous growing species. These will thrive in almost any soil or situation. The white form of this is certainly one of the daintiest little flowers we have. This does very well in the Grass where the herbage is not very rank of growth, and it succeeds under deciduous trees. The large handsomely marked leaves remain in good condition through the hardest frosts, and thus form a carpet of the freshest verdure at a season when it is so welcome. J. C. B.

SOLANUM JASMINOIDES.

THOUGH hardy in a few of the more favoured districts of this country, the *Solanum* in question must be, generally speaking, regarded as a greenhouse plant, for it is when treated as such that it is most effective. One thing in its favour is a soft or rafter plant is that the foliage is not in any way dense, so that even a large specimen of it will not obstruct a great amount of light, which is in a general way a desirable feature in a climbing plant. At the same time the young shoots are rather liable to be attacked by aphides, and if the atmosphere is too dry, red spider will quickly make its appearance and work havoc with the foliage. With a little care, however, both these can be kept in check, and then this *Solanum* will, under suitable conditions, flower for months together. I have had under my observation for some time a by no means large plant, which has not been without flowers since last November. Under glass especially, where slightly shaded, the blooms are pure white, but out-of-doors they are often tinged with bluish-mauve. It strikes root readily, and is altogether of very easy culture. *S. jasminoides* is, however, by no means the only climbing *Solanum* that ranks high as a flowering plant, for two or three species of great merit have been very attractive at Kew for the last few years. One of them, *S. Wendlandi*, is a bold, strong-growing climber, with clusters of purplish-blue blossoms, while a second species, *S. Scaevolarium*, has clusters of flowers a good deal like those of *S. jasminoides*, except that they are of a pleasing shade of pale-lilac.

S. pensile, the third to mention, has lanceolate leaves of a very deep-green tint, and clusters of deep purple blossoms. All of the above, except *S. jasminoides*, require stove treatment. Another species is *S. orisipum*, which is hardy in the especially favoured districts of this country, and may be treated as a wall plant in others. It forms a large bush, while the flowers, which are freely borne, are of an attractive shade of pale-blue. This is an old plant in gardens, and though but little known, it is where hardy a very showy shrub. P.

THE CHOROZEMAS.

THE *Chorozemas*, so well represented by *C. Lowii*, a variety or species with larger flowers than are usually found upon other species in this genus, are amongst the most useful of greenhouse plants, especially to amateurs who have no convenience to force plants or shrubs into flower. Although the *Chorozemas* may be grown into specimens large enough for exhibition, so large that they can with difficulty be moved by two men, this is not the kind of thing the general public want, and even frequenters of exhibitions have become satiated with such unwieldy specimens. One can appreciate the skill of the cultivator who has worked well and patiently to bring his plants up to the highest standard of excellence; but the primary object of cultivating these specimens being to win prizes at flower shows, they serve their purpose when the exhibitor has won the coveted award, whatever it may be, for as decorative plants for the greenhouse they are not to be compared to the smaller specimens naturally trained. One can safely recommend *Chorozemas* to amateurs because of their easy culture and the cheap rate at which the plants can be purchased. The leading dealers in these plants say that there is but little demand for them; and therefore there is but little encouragement to propagate a stock of plants. No one can complain of the attention now given to *Orchids*; they must ever command admiration; but we cannot nor ought we to compare one class of plants with the other. *Orchids* will do in a comparatively cool house in winter, but there must be a heated house for even the coolest of the *Odontoglossums*; whereas the *New Holland* plants succeed well in a house that need not be heated except on sharp, frosty nights, and the dry atmosphere in which the plants delight in the winter season is pleasant for invalids, who must have air and exercise without being exposed to cold east winds.

THE CULTURE OF *CHOROZEMAS* is very simple. Seeding plants are the best. They grow more freely than those propagated from cuttings, and make a better growth. They also grow rapidly when they have reached the flowering stage. The two main points to be attended to in their culture are careful attention to planting in the right kind of soil and placing them in a light, airy position in the house, but avoiding a continuous draught of air. The potting-soil ought to be yellow loam, such as is found on moorland pastures in the vicinity of peat, and in which Bracken or the Brake Fern grows freely. I use two-thirds of light fibrous peat with this yellow loam, and add a good sprinkling of coarse sand if it is needed. The plants grew freely and make a mass of fibrous roots, and if repotting is delayed they form a compact hard mass, and when this has taken place it is necessary to take a pointed stick or, what is better, an iron skewer and ease out the roots a little. Good drainage is necessary, and over the drainage put some of the fibre from the turf from which most of the soil particles have been shaken out. In removing the plants from one flower-pot to another, an inch all round the ball of roots should be allowed for the new compost. As a rule, all these hard-wooded plants require to be potted firmly, and the *Chorozemas* are no exception. In a few words I will point out the reason for this firm potting. The ball of roots being a compact, very solid mass, if the soil was put in loosely the water applied after repotting would pass rapidly away in the new soil and scarcely penetrate the part containing the roots, so that a plant might be suffering from want of water, while to all intents and purposes it had been freely supplied. It is to obviate this evil that the plants are picked out a little with the forked skewer, so that they may the more readily

lay held of the new soil, and if the soil is packed in firmly with a wooden rammer the water applied will pass through very much more slowly and the roots will be supplied with it. Before one of these plants is repotted the roots should be well on the moist side to avoid giving any water for two or three days after repotting, and when it is seen that water is really needed, give a good supply. Most of the *Chorozemas* have

LONG SLENDER STEMS, which make them useful to train against a wall or trellis-work; but they ought also to be trained to neat sticks to form even a moderate-sized plant. Avoid the formality of balloon-shaped or any fantastic form other than that of a bush, which should be well furnished from base to apex with healthy flowering growths. There is no need to starve these plants into flower. They flower profusely with liberal treatment, and when the plants are kept too long in one pot the leaves assume a greenish-yellow tinge, instead of a deep full green. When well established a good supply of water is required at the roots, but some discretion is needed: the points of the fine fibrous roots may be injured with too much or too little water. The plants may be placed out-of-doors during the summer and autumn months, but if the pots are fully exposed to the sun it is well to lean a slate against them to prevent injury; the pots would absorb the heat to such an extent that the roots in contact with the inner surface would be positively burned. When out-of-doors they should also be sheltered from violent winds, which would overturn even a moderate-sized specimen; a stout stick should be driven into the ground at the side of each pot, so that plant and flower-pot may be both made secure. They must not be left out so late in the autumn as to become saturated with cold rains. J. C. B.

FLOWER GARDEN NOTES.

To advise as to the best materials to employ for the most effective, and at the same time the most tasteful display in the flower garden is by no means an easy task, as so much depends on the tastes to be gratified, natural surroundings, style and formation of bed or border, and many other things. There are certain flower gardens, scores of little beds perhaps enclosed by Box edgings, and with tiny gravel walks running between them, with which it is almost impossible to deal satisfactorily. The demand is generally that each bed shall be independent of its neighbour, and under such circumstances it is a very difficult matter to blend and harmonise colours. Neither can satisfactory results be gained by filling such gardens with herbaceous plants; the latter never look at home in small formal beds, whether these form part of a running border or of some intricate design. In offering a few suggestions as to summer planting, I may say at the outset that they are applicable to what is now the favourite type of flower garden, the herbaceous border, and beds on turf. It should be the aim to fill any vacant spaces in the herbaceous borders for the summer with those things that seem most in touch with the permanent inmates. A few

TALL THINGS for the book are free-flowering *Pompon Dahlias*, the useful bright yellow single *Helianthus*, a few clumps of *Prince's Feather* and of summer-flowering *Chrysanthemums*, or if there is already an abundance of flowering plants in the background, the summer introductions may consist of such fine-foliated plants as *Solanum gigantourm*, *Wigandia*, *Ferula*, *Cannabis gigantea*, *Ferdinandia emiensis*, and a few *Cannas*. Bare spots in the front of such borders may be filled, in addition to some *Carnations* and *Violas* as there may be to spare, with *Cuphea platycentra*, *Gazania splendens*, *Diplacis glutinosa*, a clump or two of *Heliotropis*, pegging the latter once to keep it dwarf, and also a few blocks of the best of the ascotid *Pelargoniums*. In the arrangements in the flower-garden for beds on turf, the gardener has, as a rule, to adapt his planting to the tastes and requirements of his employer; in one place plenty of bright colour must be the predominating feature; in another, subtropical work; in another, plenty of large bold plants, as big specimen *Fuchsias*, Ivy-leaved *Pelargoniums*, and the like; in another, carpet bedding either by the employment of the dwarfest of plants or by the judicious blending of bright colours in foliage as would be repre-

sented, for instance, by the hrenze and tricolor Pelargonium and Coleus Verschaffelti. Of many

NEW IDEAS that have come in of late years to improve our floral arrangements, one of the best was the introduction of a minimum of tall, graceful, or large, well-flowered plants on a dwarfier carpet of flower or foliage. Instances of such planting will be found in Abutilon marmoratum with purple Petunias, Fuchsia Abundance with silvery Centaureas, Rosa of Castile, or one of the Cornelieus type of Fuchsia with purple Violas, Nicotiana affinis with scarlet Pelargoniums or Verbena, and white Marguerites with pink Pelargonium. In all the above arrangements the dot plants are given first, and may be planted with a sparing or more lavish hand in proportion to the size of bed or border. The brilliant or glowing Begonias in scarlet, crimson, or pink shades are all the better, especially if the flowers are heavy and have a tendency to droop, for the introduction amongst them of a few lighter, taller, and more graceful plants. The striped Japanese Maize is sometimes used, but this is a trifle stiff and formal, and I certainly prefer the variegated Ribbon Grass, the Sweet Tobacco, or even a few well-grown plants of Eucalyptus globulus or citrifera. Beds of Verbenas can be relieved in a similar manner.

MIXED BEDS, in which two given plants are used in about equal proportions, are also still in favour, and very pretty and effective if the colours are nicely blended and the arrangement is not too stiff and formal. Pelargonium Flower of Spring and West Brighton Gem, with respectively Lobelia cardinalis and the silver variegated Fuchsia, the silvery Centaureas and Verbenas with Heliotropes or Verbena venosa, two lines of bedding Beet or Begonia Worthiana running irregularly through a carpet of dwarf Ageratum, are a few instances of such planting, the size of plants again to be regulated in proportion to size of bed. A few large specimen Fuchsias, Ivy and other Pelargoniums, and Heliotropes are not out of place even in small flower gardens; they may be plunged on turf or in small beds, and in the latter case could have a dwarf carpet of flower or foliage to show to advantage against the several colours. There are very few, if any, of the foregoing plants that are not to be had easily either from seed or cuttings, and are therefore within the reach of all who have a little glass. Of many other things that enter sometimes largely into the flower-garden arrangements, such, for instance, as the half-hardy Dracenas, Pelms, and Aralias, it is not necessary to write; they are not everybody's plants, and as such do not come within the scope of the present notes. E.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to my designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3878.—Candytuft.—Is perennial Candytuft best raised from seed or from cuttings? Will cuttings root to the open air?—C. N. P.

3877.—American Bellbird.—Will any of your readers kindly inform me if this is the same plant as our Blue-weed or Wild Convolvulus?—J. K.

3878.—Calceolaria rugosa.—Is Calceolaria rugosa the same as Calceolaria pedunculata? It is offered in a catalogue, and should like to propagate it.—C. N. P.

3879.—Lawn tennis-court.—Will anyone kindly tell me how to make a clader or gravel lawn tennis-court? How much clader or gravel required, and probable cost?—G. GRASSON.

3880.—Campanula pyramidalis, &c.—Should be glad to know best treatment of Campanula pyramidalis and Lophospermum scandens; also if both are hardy perennials?—STANTON.

3881.—Cape "Geraniums"—Will someone kindly give directions for culture of Cape "Geraniums"? I am just starting with some cuttings? Will they live in so unheated house through the winter?—D. K. W.

3882.—Crasper for a wall.—Will someone kindly recommend a very quick-growing Creeper that fastens itself to a wall without needing to grow up a house-wall facing south-west, to cover up the brickwork?—STANTON.

3883.—Doronicum.—In our park there is a lovely plant, Doronicum austrinum. Is this anything like Doronicum Harpur-Clewis? I am going to grow Doronicums and should like a few hints thereon.—C. N. P.

3884.—Double Petunias.—Will someone kindly tell me how to grow Double Petunias? I have half-a-dozen plants in 4-inch pots. I want to have them ready for showing to August, and would like to know of a few named ones?—HALL.

3885.—Treatment of young Vines.—I have a few young Vines which I have raised from eyes put in last January; they are about 18 inches high, and have shoots at every joint from an inch to 2 1/2 inches long. Should these side-shoots be stopped?—F. H.

3886.—Substitute for rotten manure.—I have no means of procuring rotten manure. I shall be glad to know if I can use fresh horse droppings instead? I can use manure-water thus made for Palms, Lilies, and plants in a conservatory generally.—STANTON.

3887.—Clematis, &c.—I shall be glad to know if Clematis, Azaleas, Genietas, and Myrtles, can be put out now into open ground; also if the pots should be buried or plants should be removed from them? Should plants generally be buried in their pots?—STANTON.

3888.—Asparagus culture.—Will someone kindly inform me how to grow good Asparagus? I have old beds and young ones which are given plenty of manure, salt, &c., and contain the largest kinds of the plants, but the result is the same every year—viz., long thin stalks.—SCOTIA.

3889.—Lilies of the Valley not flowering.—Will someone kindly inform me why my Lilies of the Valley have not flowered this year? They are too healthy plants, but in rather a sunny position. They have plenty of leaves, but no flowers. They have flowered in previous years.—PERRYSBURGH.

3890.—Scented Pelargonium.—I find in a seed catalogue Pelargonium odoratissimum also Pelargonium roseo-scented. Which of these two is the common scented leaf "Geranium"? I want to raise from seed, as I cannot buy cuttings at anything like a low price, and I want a considerable quantity.—C. N. P.

3891.—Madonna Lilies.—Will someone kindly tell me why the leaves of the White Madonna Lilies, after growing in a flower-pot for six or seven weeks, suddenly seem to take a blight of which some of the leaves are a sample? The bulbs were planted last August twelve months in a little sand, 2 inches deep.—L. D. E.

3892.—Treatment of Smilaxes.—Will someone kindly tell me what treatment they require? I have several seedlings about 2 inches high, and should be glad to know what soil and size pots to put them in. Do they require heat, or would they do in a conservatory without heat, and that is shaded during the day?—MALVINA.

3893.—Mildew on Vines.—I shall be glad to know how to treat Vines (Black Hamburg and Buckhead's Sweetwater) which are much mildewed? Being in a greenhouse, they are only now blooming. May sulphur be applied to leaves and stems in this stage, or will it be productive of rust later on? Full instructions will much oblige.—BANKSIA.

3894.—A leaky pond.—I have puddled a pond by putting 7 inches of clay in it well worked up, but I find the water gets through. I may say the clay was put in all at once by throwing in as hard as possible, after which it was smoothed over, and the water let in at once. Will someone kindly tell me where I was wrong? The bottom of the pond was rammed very hard.—AGNA.

3895.—Ivy and Grass.—Is it too late to cut back the Ivy on my house? It is cutting badly, and the ladders are there now. If I have to pull it off I must go to the expense and trouble of hiring long ladders. Can I do anything to make the Grass grow close round the trunk of a large Oak tree on my lawn? At present the ground is bare within 4 or 5 feet of the trunk?—J. B. P.

3896.—Young Myrtles.—I have some young Myrtles raised from cuttings four years ago, which disappoint me in showing no bloom. They are healthy-looking, and full of growth, kept in a greenhouse, except during the warmest part of summer, when they stand out-of-doors to assist in ripening wood for blossoms, which, however, do not come. Can any reader kindly help?—DOWN EAST.

3897.—Roofs for a wall.—Will someone kindly advise me, through GARDENING, what kind of Roses to plant out now against a wall with a south aspect? I have a Gloire de Dijon on the same wall doing splendidly. Will someone also tell me what kind of Roses would do well on my greenhouse, south-east aspect? I want to put one against the wall and others in pots (not heated).—BOURNEMOUTH.

3898.—Seedling Pelargoniums.—Nearly two years ago I sowed some seeds of Pelargoniums, from which I have now several healthy plants of each, named varieties Zonal and Regal, in 5-inch pots. I thought that possibly some of them may have bloomed last season, but they did not, and so they seem likely to flower this time; yet the plants seem healthy, but some are stronger than others. I should be glad to know how to get them to flower?—F. M. J.

3899.—Arrangement of a greenhouse.—I have a large greenhouse, 14 feet by 16 feet long, divided into two sections, one of these, 14 feet long, is divided into two, and the other, 20 feet long, is used as an ordinary

greenhouse. I propose now to add a three-quarter span house, 16 feet long by 10 feet 6 inches wide, and shall be glad of any suggestions as to the best mode of utilising it, and as to internal arrangement. I thought it would do best for a cool-house.—SOUTH LONDON.

3900.—Mushrooms.—Will someone kindly give me some advice under the following: Some few weeks ago I made a Mushroom bed, to the usual way of fresh horse-droppings, after the usual preparation of manure. I have spawned the bed six weeks now, and there is no sign of Mushrooms at all, but there is some kind of stuff coming up all over the beds which I cannot understand. I should be glad if someone could tell me the cause? The soil was sifted, and perfectly clean, and the spawn was from one of the largest seed firms in England.—GASTNER.

3901.—An enemy to the Auricula.—For some years past I have been much pestered with a leaf-roller, a species of Tortrix which on every opportunity attacks and destroys the heart of the Auricula here. This is the month when it first appears, and continues its ravages for some time into the month of June. Will some experienced and extensive growers of this plant kindly say if they are so troubled? The larvae is blackish in colour, sometimes it is of a reddish tint, and when full grown about half an inch, or may be a little more in length. Even when the plants are protected the pest finds its way through the ventilators of the frame or holes in which the plants are kept.—P. RENOVATOR.

3902.—Chrysanthemums cutting down.—I have this year sown about 100 plants of Chrysanthemums into 12-inch pots, not having a smaller size at command. They were stopped when they were about 5 inches high; some of them I have not stopped, and these have one or two single stems 1 foot high; those I stopped have three or four stems on each plant—viz., Soleil Levant, Etolle de Lyon, Condor, &c. Those that I have left to one single stem are Avalanche, Puritan, Miss. De Sevin, &c. I see an article in GARDENING, April 15th, on the culture of Dwarf Chrysanthemums by "K. M.," who speaks of a system of cutting down them, and says their second sized pots, 6 inches. I am wishing to know if I can cut my plants down now with safety, or shall I allow them to grow with three or four shoots to a stem, with a certainty of their being dwarf and producing large blooms?—ANXIOUS.

3903.—Building a conservatory.—I am erecting a villa, at the end of which I purpose putting up a lean-to conservatory. The bath-room is over the hall. I am thinking of getting sufficient heat for the conservatory by carrying the hot-water pipe through the place the conservatory is on its way to the bath-room, with a duplicate pipe, which would not go into the conservatory, for use in summer, when the place would not require any artificial heat. Can anyone kindly inform me if this is, in his opinion, practicable? Or does any one know of any place or places where it acts? Personally, I have confidence that it will not, as the hot-water would always be circulating through the pipes, and, in addition, there would be warmth from the two fires at that end of the house. I could have an extra trap for every eighth. The aspect is south-east. I shall be glad of an opinion in the next issue.—J. ROBINSON.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3904.—Imported Odontoglossums (L.).—Well, it is rather late to think of starting Odontoglossums just brought home from their native country. However, if you have some in this state, although late, they may be potted in the same mould that I have before advised you to use for these plants. Keep them cool and shaded, and the atmosphere in a nice moist condition.—M. B.

3905.—Cattleya aurea (L.).—This plant flowers at once from the sheath made, and before the growth is made up, and this kind should not be heated before flowering, but immediately after flowering it must be kept cool and dry, in order to prevent its growing again before spring.—M. B.

3906.—Cattleya Victoria Regina (L.).—I do not know how this species does tend in its flowers, but if you have a plant with a sheath in the autumn I should treat it kindly. Keep the plant in a fair temperature and nice and moist, but do not let it get too wet, and its bloom will push up all in good time. C. Alexandrina, &c., in the same manner.—M. B.

3907.—The Meadow Rue.—John says what is the name of this plant, and how grown? Well, there is a host of species and varieties of the Thalictrum, which is the generic name of these plants; but many of the kinds are grown in our gardens, and the foliage is cut and used in a great deal of Meadew-hair Fern, which very much resembles, and for this I should recommend you to T. minus. This may be grown in the open air in any good garden soil, chiefly loamy.—J. J.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Naming Fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind are very assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be returned. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

BIRDS.

ZEBRA FINCHES.

In a recent issue a query was asked relative to Zebra Finches and their nesting, and as the question is a peculiar one, and an answer to it is forthcoming in the few publications which exist treating on foreign Finches, the following particulars may be found acceptable not only to "Herbert B. Baring" but to other readers of the Bird notes. For some years now I have kept all the ordinary kinds of foreign Finches, to study their habits, food, &c., and the chances of breeding them. With one exception, the Zebra Finch has the greatest desire to nest. When first brought, newly imported, the birds are shabby, and in poor plumage, evidently weak from the long voyage, and bad food and ventilation. The first thing they appreciate when put into a nice cage is the fresh, coarse gravel, of which they pick up quantities. After a few days they begin to plume themselves, and take a daily bath until they are in perfect condition, not a feather out of place. If possible, where nest-boxes or Cocoa-nut-husks are provided, the Zebra Finches choose one, after having inspected every hole and corner of the aviary, and to it they carry every blade of Grass or feather they can get hold of, and continue from time to time to take fresh building material until the eggs are laid, when building ceases for a week or so only. The nesting or sleeping-box must be of sufficient size to permit of both birds having plenty of room in it, for until after the first egg is laid both birds share the nest, and even then when incubation is proceeding they frequently go in and out, or are both inside at once. The eggs are small, white, and semi-transparent. When about to lay the hen utters frequent squeaks and seems excited and fidgety; she should have plenty of green food, Chickweed, and flowering Grass, and besides this fresh gravel. Shell gravel and some chalk freshly pounded every day and flung into the cage, of this both she and the cock will eat quantities. The number of eggs vary; they are laid each morning between 6 a.m. and 10 a.m. The hen appears puffy and inclined to sleep. Both birds are so much in and out of the nest that it is difficult to tell when there are eggs, and if the nest is examined the birds will purposely throw out or peck the eggs. Evidently "H. B. Baring" owed his lack of success to unfertile eggs. I have been told, and from experience am inclined to believe it, that without a daily supply of flowering Grass, Zebra Finches will never rear young. This important item he does not enumerate as having given to his birds. When the young are hatched, the cock will eat greedily of any soft food, although the young are principally reared on semi-digested seed. Two days after hatching the young bird first utters its curious cry for food, and if attention is paid about 9.30 a.m., it will be clearly heard, or about half an hour after the daily fresh seed and water has been put into the cage. Incubation lasts 10 days from the time the egg is laid and another fortnight elapses before the young bird leaves the nest when it is fully fledged. They come out daily in the same succession the eggs were laid, and are fed by the father till six weeks old, long after the hen has begun to sit on another batch of eggs. The cock sits most of the day, and the hen all night. When nesting Zebra Finches are somewhat spiteful to other occupants of an aviary, and allow no interference with their nests or its vicinity. When once acclimatized they seem as hardy and prolific as Canaries, but the hen frequently dies from weakness or chill, from too prolonged laying. Yet so devoted are these little Finches that [6] (text to be corrected) sexes. Castor-oil is the only safe remedy, and

I have frequently saved the life of an egg-bound hen by applying it, and then turning her loose in the aviary again. After a severe case of egg-binding a hen does not attempt to lay for some time. My advice to "Mr. Baring" would be to let his birds alone, give them a Cocoa-nut-husk to build in, with fresh heads of the same flowering Grass found in every garden. This they will eat as well as build with; also give fresh green caterpillars if they will eat them. Unless his birds have been quite three months in England, breeding is not likely to be successful. Never give ants'-eggs, as they stimulate and excite the birds so much that they destroy their eggs at once, and if they have young birds may even desert them in the nest efforts to nest again. Laying commences about ten days or a fortnight after pairing, but there seems no rule for this. For soft food I used the penny packets of Hartz Mountain, or similar food, but the birds never touched it until overwhelmed by the hard work of having to feed a nestful of little birds. Zebra Finches will pair with a hen of any species, so desirous are they of nesting; and one cock Zebra Finch, in an aviary, is invaluable as a foster-father to any little birds who will accept his attentions. They will also hatch and rear other birds' eggs. I feed them on Canary and White Millet, this latter being more nourishing than the dark, dry Indian Millet. Any small garden or Grass-escote they will eat are also wholesome for them. It is dangerous to allow them to breed in cold or catchy weather. To prevent their doing so, interfere with their nest and pull out the lining, &c. EMMA ELIZ-THOMTS.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free 5d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 8d. Complete set of volumes of THE GARDEN from the commencement to end of 1892, forty-two vols., price, cloth, £30 10s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 5d. London: 37, Southampton-street, Strand, W.C.

EVERYONE WHO HAS A GARDEN, GREENHOUSE OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. E. WILK, F.R.S., F.C.S. Trially Col, Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, lively flowers grown to perfection, and fruit-trees made to bear in abundance. Selections from Hundreds of Testimonials. Post free from

JAKEMAN & CARVER, Printers, Hereford.

THE CONICAL BOILER is the Cheapest, most Efficient, and Economical Boiler ever invented. For heating Greenhouses, Conservatories, Warehouses, Churches, Chapels, and for Amateurs (Gardeners). Requires very little attention. Will burn any kind of fuel, and cannot burn hollow. Sole Makers: NEWSUM, WOOD, & DYSON, BEESTON ROAD, LEEDS. Price and Testimonials on application.

ORCHID PEAT.

PREPARED, ready for use, all fibres, 10s. per sack; 5 lbs. 4s. 6d. SELECTED, in blocks, very fibrous, 8s. per sack; 5 for 37s. 6d. SPOON QUALITY, 5s. per sack; 5 for 25s. 6d. BROWN FIBROUS PEAT for Amateurs, Rhododendrons, Ferns, &c., per sack; 5 for 1s. 1s., and 3s. per sack; 5 for 12s. 6d. PEAT-MOULD, LEAF-MOULD, and FIBROUS LOAM, each 2s. 6d. per sack; 5 for 12s. 6d. PREPARED POTTING COMPOST, 4s. per sack; 5 for 18s. All sacks included. Send Postage Order for Sample Sack. Special terms to the Trade. For Price List apply to—The Forester, Joydon Wood, near Rawley, Warr.

TAMWORTH RED EGGS FOR ORCHIDS, Ferns, and young plants. Pure pedigree bred; a rough recommendation as good blood plus, also for creating a possess. Price and full particulars on application to—WATLIP, Manor Farm, Kington, N.C. Agents.

NETTING, Tanned and Waterproof, of all kinds, for garden purposes. Cheapest house in the Trade. Write for samples and prices before ordering elsewhere. Numerous Testimonials.—SHEPHERD & CO., Net Manufacturers, Lowestoft.

SPECIALITIES FOR GARDEN, &c.—BLUE CLOTH CAPES, Strap and Buckle, impervious to wet, 3s. 11d. each. BLACK OILSKIN CAPES, Strap and Buckle, impervious to wet, 3s. 11d. each. GLENNONE NAVY, 4/6 each (post double). 3s. 11d. each. BLUE ATLAS BLANKETS, 4/6 each. 2s. 3d. ARMY BELL TERN, 10 each. 12 each. Pegs, Ropes, Poles, &c., complete, 12s. 6d. per dozen. MOORE & CO., Lauristdale Buildings, Aldersgate, London.

GAROEN AND PLANT PHOTOGRAPHS.

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded.

The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; cut flowers, prettily arranged; pretty cottage gardens; our best fruits on the branch or branobes, not in dishes; standard vegetables; good flower-gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS.—A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS.—First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or bush-fruits, to be shown on the branches, not in dishes. No prize will be awarded to photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES.—A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not want to exclude rose novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in June, 1893.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, also labels, especially those made of zinc (which should be removed when the photograph is being taken), and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted simply, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the sources whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The holder is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Covent-garden, London, W.C. and marked "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

CHRYSANTHEMUMS.

CHRYSANTHEMUM BLOOMS FOR SHOW.

HOWEVER well the blooms of Chrysanthemums, incurred in particular, may be cultivated, if they be placed upon the exhibition stands as grown there will be but little chance of their owners gaining premier positions in the leading contests. The would-be prize-winner, then, should become the possessor of a pair of strong steel forceps with a good grip to pull out ill-formed and unperfected florets, also bene tweezers for placing the latter in an even manner. These, with a supply of cups and tubes, can be purchased from any specialist in this popular autumn flower. A good time to make a start is when the bloom is about a quarter open, for even at this stage a floret may decay or come in form like a quill; others may reflex instead of incurve. Promptly remove all such, and it may be necessary to just look over all of the show flowers every second or third day until fully out. The largest kinds—Queen of England being a good example—require the most work. These sometimes form a far greater number of petals that can possibly develop. Thin them out as the bloom is expanding on the plant. When about three parts open, the centre may be a confused mass of embryo florets. It is well here to quite clear these out (also the yellow disc which forms in some) carefully, but leaving a hollow part half an inch or so in diameter. Room is thus given for the rest to fully extend, and the centre of the bloom is knit up with petals large and of fine texture. Finish in this part of a bloom is important, the top or point being the first to arrest the eye. The variety Princess of Wales is a capital type of another class. The defect most noticed here is a tendency to produce petals shorter than the bulk; remove these with the forceps as the flower opens.

THE JAPANESE sorts need very little of this pulling-out process, but the opening of many of them is improved by an occasional tap, which is generally enough to loosen the entwined florets and make room for others that may be pushing forward. Tie the blooms in an upright position if inclined to be top-heavy, and do not cut a flower thinking it will open and keep better in water, but, instead, when fully out, remove plant and all to a semi-dark and dry room until a day or two previous to the show. Begin the final operation of arranging the petals in good time, so that it may be done if possible by daylight, and also that it may not be hurried. I am quite satisfied of this (provided, of course, the flowers have been well grown, for a bad specimen cannot be manipulated into a good one), that the more time one spends on the incurred blooms the looser will the judges, as well as the public, linger around them. I am told that a very skilful exhibitor of the incurred Chrysanthemum occasionally gives from three to four hours to a single bloom. If a stand of twenty-four were each to require this amount of time, simple arithmetic will show how many days before a show we are to commence. I think, however, the above is a little wide of

the mark. There are well-known cups and tubes, such as Beckett's, Jameson's, Walker's, and so on. But the fault of these—at least, for incurred blooms—is that the hole where the stem goes through is so large that it is very difficult to fasten the blooms in tightly. For this reason I prefer the old wooden cup, similar in shape to an egg-cup. It is vexing after a journey to find the blooms loosened, and the work of placing the petals obliged to be done again. Whichever appliance is used, cut the flower with a long stem, so that it may be conveniently handled, and after passing it through the hole of the cup, fix the same, but not too tightly at first. Then holding the bloom as near as possible upside down in one hand, place each petal, starting at the centre, in a position renning to this latter point. Steel or bone instruments can be used, and what is very desirable is a light touch, damage to the tender petals being easily accomplished. If the egg-shaped cup be used, other appendages are the tube to hold water and a piece of zinc, called a telescope, to take the cup at one end and the tube at the other, so that the bloom may be raised or lowered at will. The Japanese varieties with long drooping flowers require very little preparation, and in nearly all cases look best shown as grown. Do not use wires, cards, or the like to make all the blooms appear larger, thus getting diameter at the expense of depth, the last being an important point in a good flower.

FRESHNESS and brightness of the colours are often lost sight of by those who start exhibiting. They too often choose only these blooms which possess extra size, and wonder why smaller ones have gained the prize. Stands well painted of a deep-green colour and nicely varnished tend to give a rich appearance to the blooms. The present standard size is 24 inches by 18 inches, 6 inches high at the back and 3 inches in front, to hold a dozen blooms. The same size is need for all classes. This season, however, will see the last of such small boards in the case of the Japanese flowers, it being settled, I think, by all the more important societies that the new size for these giants shall be 23 inches in length, 21 inches wide, 8 inches high at back, and 3 inches in front. The change will give 1 inch more between each bloom, and the extra height at the back of the stand will throw the flowers forward and make it easier to see those in the back lines. Whatever kind of box is employed to convey these stands of blooms to the exhibitions, a detail worth remembering is the necessity of fixing everything—tubes, stands, and so on—as firmly as possible; then a little shaking will not do the blooms any harm. Blooms of incurved, Anemone-flowered, or true reflexed all look well, arranged about 2 inches clear of the stands. This position assists the judges, who can thus see every part of a bloom. The blending of colours will be done according to individual taste, but in this, as in other details, not a point should be lost.

Early-flowering Chrysanthemums.

The growing section is known as the early-flowering Chrysanthemums, whose time of

blooming is about mid-September, and must not be confounded with annual Chrysanthemums, raised each year from seed for the enrichment of the border. One fault against these herbaceous kinds is a want of variety in the colour of the flowers, but with the acquisition of new kinds, this blemish is gradually disappearing. The best is Mme. Desvraege, that beautiful Japanese variety, producing wreaths of bloom in the late September days, and very easy to grow, whilst its sports, C. Wermig, and such forms as Mrs. Hawkins may also be made note of. If only one kind can be grown choose Mme. Desvraege, cultivating it in pots and planting it freely in the border or bed. Gustave Grunerwald (silvery-white, tinted with rose), La Vierge (white), Lyon (purple), Flora (yellow), Vice-President Hardy (golden, edged with rosy crimson), Alfred Fleuret (lilac-rose, which passes to white), Mme. Jolivar (white), Mons. Pynaert van Gsert, (yellow, with reddish stripes on the florets), Nanum (white), Anatisia (magenta), Frederick Marronet (bronze), Mme. Piccol (rose-purple), and Mme. Charvin (rozy-violet) are all of great beauty. A very simple way of growing these early-flowering kinds is to strike the cuttings in the month of February. Keep them sturdy by stopping the shoots about twice. Pot on the cuttings into 5 inch pots, and when all fear of frosts is over plant them out into the positions they are to occupy, where they may remain for years if so desired, with just a little covering of coal-ashes or Cocoa-nut-fibre refuse in the event of very severe weather. During the summer give water if the weather is very dry. Tie the shoots to stakes to prevent injury from winds, and do not stop them, but simply aim at getting a profusion of flowers. A few good roots put in now even will flower in the autumn.—T.

3902.—Cutting down Chrysanthemums.—"Anxious" has made a mistake in placing the plants singly in 12-inch pots, which size is much too large. Two plants in each pot would have been much more advisable in every respect. If extra large blooms are required the plants not topped should be allowed to grow with one single stem until they make their first natural break, which will be shortly, and which is the result of the formation of a flower-bud in the point of growth checking the letter for a time. Remove at once the flower-bud and select three of the strongest shoots near the point of the plant, pinching out all others. These selected should be tied to a stake in the centre loosely, yet firmly. In time a flower-bud will form in the point of each shoot; if the stake placed at the right time from that had the flower on each will develop. The varieties named, as at present untopped, are naturally of a dwarf habit. Marie de Sevra is not a large-flowering kind, as flowers go nowadays, but it makes an excellent bush, therefore I should advise it to be treated as one. Those that were stopped and have now three or four shoots to each I should advise they be stopped again twice, when five inches of new growth is made after each topping. Afterwards allow the shoots to grow away at will; the result of such plants will be abundance of flowers for cutting; the plants under this method of treatment ought not to be cut shorter than 10 to 12 inches in bloom.—E. M.

GARDEN WORK.

Conservatory.

Luouilla graminea is a very handsome water-flowing shrub. It is not often seen in a good condition in a pot; but it is very easy to manage if planted out in a good bed of peat and loam, either as a spreading bush or trained over a wall. If treated as a bush in the border the knife should be used freely in spring, and if the position is a fairly light one every young shoot that breaks away if encouraged to grow freely will carry a large cluster of rose-coloured fragrant flowers in November or later. Weak soil-water may be given once a week when the plants are making growth, and again when the flowers buds have formed. The Fimelcar are a handsome race of New Holland plants, very useful to the exhibitor at this season; but one does not often meet now with the grand specimens that used to be in the collections of Mr. Thos. Bates and the Messrs. Cole, of Manchester. Henderson and spectabilis roses are two of the best; should be potted in good peat and sand, and watered carefully. No one would water a hard-wooded plant at this or any other season without first rapping the pot with the knuckles to test its condition. Good companions for the Fimelcars are: Pheonix proflera Barnesii, Tetraena verticillata, Polygala Dalmaniana, Leobachnautia biloba major, Mitrasia coccinea, Tovea Celsii (rather difficult to do well), Gonystelia tulipifera, Boronia rumicoides, and Aphelaea macrauba purpurea. Such things do not mix well with soft-wooded plants. They may be moved to the conservatory when in flower, but at other seasons will be better in a light house of moderate temperature by themselves in company with other hard-wooded plants of similar habit and requirements. Gather seeds of choice Primulas just before the pods ripen, and lay in paper in an airy room. The seeds may be sown as soon as ripe, as new seeds are better than old ones. Night air is beneficial to hard-wooded plants when the nights are mild. Some discretion is necessary in giving night air to keep out cold winds. By adhering to the weather will become settled a bit, and then more night air can be given. Cuttings of the young shoots of Daphnes will root new under a half-glass in a shady position, or will also cuttings of Azaleas with the young wood from which the cuttings are taken, just getting a little firm. The pots must be well drained and these fitted up to within half an inch of the top with sandy peat, pressed firmly down, and watering, leaving the pots an hour or two to settle. Named Chinerias just out of blossom move to a cold pit, and give water enough to keep the soil moist to encourage the efforts to break away from the bottom. These latter should when fairly started be taken off with a sharp knife with some roots attached, and be potted singly in small pots kept close and shaded for a time in cold frames, and be potted on as required. It is named sorts might be grown again with advantage, as the quality of seedlings if the seed is purchased is so inferior. It is better to grow a few, all of which are flowers of good quality, than had room for a lot of rubbish. Keep Kalosanthus in a light position.

Stove.

Variiegated or ornamental-leaved Begonias are useful subjects to the small stove. Half-a-dozen good varieties will be found in the following: Arthur Melet, Marahella, Greig, Sourenir d'un Ami, palmata, and alba picta. They are not difficult to grow if not overpotted or overwatered. A compost of two-thirds peat and one-third loam with some sand will suit them. Everybody should grow a few Amaryllis. Some of the varieties are rather expensive to buy, though seedlings are cheaper, and if we start with small collection of named varieties seedlings may be obtained from them. The following half-dozen may be obtained at a reasonable price: Johnsoni, Prince of Orange, Aulica grandiflora, Brillant, Dr. Meester, reticulata. These may be grown in good loam and leaf-mould. They are not much trouble, as they will rest in a dry state for several months in the year, and will not require repotting every year, and seedlings are not difficult to raise. Give liquid-manure to flowering stove plants for the most part when the flower buds appear; there are exceptions to this rule. The Eucharis Lily, for instance, may have weak stimulants whenever we wish to hasten the production of the flower-spikes, even though they are not visible. By the use of stimulants with alternate rest-days I have been able to take three crops of blossoms a year. As a rule, stimulants need not be given anything till the pots are filled with roots, and seedlings are not difficult to raise. The disadvantages of permanent shade will be felt, no clouds appear again in the sky. If dull, cold weather returns, a little fire occasionally will be necessary. Nip off the ends of the growing shoots of young plants making free growth.

Plants for the Unheated Greenhouse.

This is a good season for buying in young plants for growing on. The plants we have had with us during the summer are more likely to be available during winter than if we buy in late in the season. Aralia Sieboldi, A. S. variegata, both of these are of easy culture, and are hardy in sheltered places outside. Arundo donax variegata, Bambusa Fortunei variegata, Eulalia japonica variegata, Phorolium tenax variegatum, Sedum carneum striatum, probably for draping baskets, Fertilium grande, Badum Sieboldi variegatum, Vinca elegantissima, pretty in pots and baskets, Anthericum variegatum, Geranium glaucum variegatum, Vinca flammulata variegata, Dracena indicata, this is fairly hardy, and if the winter very severe the leaves might be tied together and some canvas wrapped round the plant. The Fan Palms (Champrope Fortinoel and humilis) are quite hardy under a glass roof. In many places they pass through severe winters outside uninjured.

Ferns under Glass.

Where there is only a small house for the Ferns the Tree-Ferns are inadmissible; but in a large house half-a-dozen Tree-Ferns give one an idea of the tropics at once. Of these Adiantum acrostichum, Lyonia dealbata, Dinkonia lantanae, D. squarrosa, Lomaria glabra, Didymochloa lunulata, will make good selections. Lomaria glabra may be grown in a small house, as it is of dwarf habit. Shade

* In cold or northern districts the operation is to be done to the Garden. Work may be done in the open air for a fortnight later than is here indicated with equally good results.

should be used judiciously where fronds are required for cutting; if exposed too much they lose their dark-green colour, and if heavily shaded the growth is too tender, and drops; the moment the plants are taken out of the house or the fronds used in a market. There are a plenty of ripe ones for many of the plants which may be gathered and sown. The soil should be treated with boiling water to kill the vegetable organisms contained in the soil. Fern-spores when good will grow in any damp, moist situation, kept close and shaded. Ferns established in pots will require a good deal of water now, and the atmosphere must also be generally moist.

Frames.

Fill up all vacant frames with something profitable. Where many flowering plants are required in winter some empty pits or frames must be reserved for such things as Begonias, Polkaettias, Justicia, and other winter-flowering stove-plants, which will do better in July and August and the first half in September in a pit than in the dry atmosphere of a house. Frames also will thereby be required for Cystopteris, Primulas, and Cinerarias; but when these wants have been provided for all spare frames may be filled with Cucumbers and Melons or Tomatoes.

Window Gardening.

It is as well, I think, where many window-boxes are required, to plant them in as many different ways as possible, or perhaps to have them in sets, each set to be planted differently. In the course of my rambles I see a good many window-boxes, and these are planted in the same way with the same kinds of plants. Why not introduce more variety and get out of the well-worn track? Tuberosus Begonias are coming on now, and will take the place of the Peiragoniums, which are going off. One of the best Begonias for a window is the old Weltoniana. I almost wonder the hybridist has not done more with this. One of the best Ferns for a room is Pteris tremula; if a second is required Pteris orealis comes in, and Madragalm with care may be kept in condition for a long time, but will not last long where gas is burnt unless covered with a globe.

Outdoor Garden.

We have now a welcome change in the weather. It is quite a great relief to have it, as it does not contain much rain, and up to the time of writing the rainfall has been very light. Still, as the change has come, we hope the dripping June, which the old proverb says puts all things in time, will help to repair the damages caused by the long drought. There is yet time to sow a few hardy annuals for late blooming, but they never do so well as those sown in March and April. There has not been much lawn-mowing lately, or rather there has not been much reason to cut, though the mower does the turf, and stops the Daisies from seeding, so I think it is better to run it over the lawn occasionally for that purpose. During the time the bedding-out is in progress minor matters sometimes get in arrears; but now the bedding is finished everything must be fetched up to date. Hardy flowers in crowded borders where it was impossible to water effectually have been not so interesting and effective. I am afraid too many act upon the notion that the borders surrounding the garden are the best for the most interesting. Many of the finest bed plants are strong-rooting things, and will not thrive long in a crowded border, which is never or but rarely manured. What a job the watering has been! How often during the long drought I have wished for something like the overflowing of the Nile had put in an appearance here. Men are slow to learn lessons, especially when they involve expenditure. Many plants in the borders are now requiring stakes and ties, and must have prompt attention. Carnations are running up fast, and the ties must be so arranged that the stem can ascend without risk of being splintered off.

Fruit Garden.

There has been a fierce battle with insects in poor, hungry gardens, and the battle is not yet won. Very probably in some instances will be little better than a drawn battle. The trees and other fruit-bearing plants have not profited so much from the sunshine as they might have done, because the trees have not been made to meet the wants of the trees in a season like the present. Pests in some gardens have been bit hard, though the trees on walls are looking well. I expect the cold east winds are in many cases responsible for the paucity of foliage on the Plum-trees. Where the trees have been well cared for Peaches and Apricots are a full crop, too full in some instances which have come under my notice. It is difficult to find any determined enough to do justice to the tree when the fruit has been so plentiful, for overloading must be paid, through these migrating circuitous stances of which all may take advantage, which may be summed up in one short sentence, "Give more nourishment." Pines should be overhauled during June. The plants which are showing fruit may be top-dressed and receive stimulants in the water, which should never be used cold, either for watering or syringing. Succession Pines shift into larger pots. Suckers may be taken off the tree when the fruit has been so plentiful, and be potted in suitable sized pots and be plunged in a warm bed in a close pit. It is customary to remove the beds during the time the potting is sowing, and the old plunging soil, whether fan or leaves, should be turned over, some of that which is much decayed take out and a certain proportion of new man and fresh leaves brought in to put up a little new file into the beds. Do not daily over the work, as Pines suffer from exposure.

Vegetable Garden.

Cardoons are not much grown, but a row or two comes in useful where good cookery is appreciated. The plants for the earliest crop are generally raised in pots and planted out in the trenches about the end of May. The later rows may be sown in patches 15 inches apart in the bottom of the trenches and all removed, except one, if they all grow in each batch. The trenches should not be less than 5 feet apart and should be a foot deep, and 15 inches wide, and manured some as for Celery. Main crop of Celery may be put out now as for Celery. There are several ways of growing Celery. Where really fine heads are required the sledge row system is the best of sowing or cooking. Useful Celery may be grown in double rows or in beds for summer use. If cooking the blanching may be done by lying several thicknesses round the plants with or without earthing up. The rows require

the air from the plants and branches more speedily than earth. Do not forget to plant a bed of the Turnip-rooted Celery or Celeriac. It is very good for kitchen use, and a greater weight can be grown on the land than in the case of the ordinary celery. It is a good border of Turnips for summer and autumn use. If the fly or beetle appears on plants just up dust with lime and stir the soil freely. Velich's Red Globe is a good variety to sow from this onwards. Plant out Brussels Sprouts and new Walcheren Cauliflower for autumn. Much Tomatoes in houses with old manna as soon as the frosts are setting freely. They require a good deal of enrichment when heavily laden, and I find this top-dressing of manure comes cheaper than artificial. Place a thick mulch round the hills of Vegetable Marrows, Ridge Cucumbers, and Peas. K. HODDY.

Work in the Town Garden.

Carrots are an unusually early this year. In a very exposed garden I have some already showing colour, and in sheltered places in the south they are in some cases already expanded. The flower stems should be supported with the sticks at the rise, but do not draw the sticks to the stems will bend and perhaps snap; especially when firmly planted (as they always ought to be) in a bed of deep and moderately good soil. These plants suffer less from drought than almost anything else, yet, at the same time, they should have a good watering occasionally, when no rain falls for weeks together, particularly if the soil is naturally light and porous. Anything like fresh or rank manure must be avoided for these plants. A little thoroughly decayed and sweet material from an old hot, or manure bed, or some good leaf-soil, being quite sufficient. They enjoy also burnt earth and old mortar rubbish, and unless these were added when preparing the beds, a top-dressing, consisting of one part each of the foregoing, with an equal part of fresh or maiden loam and a dash of bone-manure or some well-rotted fertilizer, applied now, just as the plants are advancing into bloom, will be found highly beneficial. If large blossoms are wanted the plants will do well. Campanula persicifolia alba plena is a lovely thing to the hardy town garden, or, indeed, in any other just now. There are both single and double blues, as well as white, of this plant; but the one mentioned is a real gem, either for cutting or ornament, and nothing can be more easily cultivated. All the Campanula, or nearly so, are good town plants, and there are a number of them, varying in height from 3 inches up to twice as many feet. C. pyramidalis and its white variety are beginning to push up their stately spikes of bloom also, and plants in pots should be assisted with liquid manure. The white variety is a splendid thing for conservatory decoration. Seed of all these may still be sown, and with good culture the plants will flower freely next season. Redding-out is progressing rapidly, and the showers we are getting will give the plants a better start than any amount of watering. Single Petunias of a good strain make a lovely bed in a fine sunny season; but, like the Petunians, they are bad in wet weather. Both these flowers will do well in a poor soil, made firm. On the other hand, the Tuberosus Begonias revel in a "dripping time," soil some of the beds are planted with such we are sure of some flowers, whatever the weather may be. There is time enough yet, however, to plant out Begonias and other tender things; as a rule, the second week in June is early enough. H. O. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from June 3rd to June 10th.

Just finished bedding out. It is well to one's mind to get this work over, as everything else has to give way to it. Fortunately there is not so much of it as there was a few years ago. Several of the ribbon borders have been planted with good selections of hardy flowers, and I find them so useful for cutting, and when one looks back over the last week's work, it is a wonder how the hedges in the country lasted so long. Busy in the Tomato house, tying, stopping, untying, and watering. The fruit ripening fast now I had a thick mulch of manure over the borders very useful, nourishes the plants, and gives so much watering. Planted main crop of Celery; the bulk of the crop is in sledge rows. There will be a few trenches with two rows in each, and a bed will be planted on the level that will be blanching with stakes for late use. This bed will consist of a number of rows planted a foot apart, and be planted with the late sown plants, which will not be till late in spring. If severe weather sets in the bed will be sheltered with horrids thatched with straw to form a sort of open-roof over the bed. I have never lost any plants from frost when sheltered in this way; the thatch keeps off heavy rains as well as severe frost. Looked over Vinerias to remove laterals. Fortunately I have now been enabled to clear out the plants and have a better crop of young plants in fruit houses so much in winter and spring. I had early in June every house should be cleared, except it may be a stray plant or two of something special. Nailed on young shoots of Peaches and Apricots now walls. I have, as usual, a good crop, and this I attribute to the sheltered condition of the site of the garden, which enables me to secure a crop without using heavy coverings. These are very likely to be kept on too long and the growth weakened by so doing. Potted on Chrysanthemums, Zonal Pelargoniums, and other plants for winter blooming. Chrysanthemums after potting are fixed in their summer quarters, the tops of the stems being secured to wires. The plants will stand in single rows so that sun and air can circulate freely among them. This is a necessity. When the plants stand thickly in beds there is sometimes a difficulty in getting the growth ripened. Planted several rows of late Peas in trenches. The trenches were prepared several weeks ago and are now in good condition. Sutton's Sulham Prize is planted larger. It is a good variety, strong and vigorous, and other plants of the same variety are planted in Aralia, Grevillea, Cyperus, &c. Filled several baskets with Achimenes. Cucumbers in houses are top-dressed every week now; not heavily, but enough new compost is placed over the roots to cover them. Sowed Fern spores in pans in shady part of propagating-house. Pans are covered with squares of glass. Moved a batch of Tuberoses

they may be planted out in the positions they are intended for. You will by this treatment lose fewer than if they were left in the open. Nice shoots will strike, and may be put in pots, or if a little bed of light soil can be made up in a shady border insert the cuttings there, placing a handlight over them. I have struck many in this way. As regards raising from seed, it is important to get the stock true, as some kinds especially vary from seed, whilst some do not produce much seed here, as *I. gibraltaria*, which,

a moist, shady spot, and the soil should be rich, yet not heavy. Half the poor results seen in gardens in the culture of this flower are due to bad management, or rather no management at all, as the plants are simply neglected, and left year after year in the same position without any thought of their requiring fresh soil and situation. You had best, in forming a new bed of them, put the crowns about 3 inches apart, and, to get the best results, give a good dressing of well-decayed manure, and this may be repeated each year.

Hardy Ferns in a London garden. (See page 191.)

however, is not difficult to get from cuttings. The best *Candytufts* are: *I. Garreuxiana*, *I. Princi*, *I. correaeolia*, *I. gibraltaria*, and *I. semperflorens*.—C. T.

—The perennial *Candytufts* may be raised from seeds, but are more readily propagated by division and cuttings. If there are no hand-lights or frames to place the cuttings in, it will be better to propagate by division. They are well known and useful garden plants, easily grown if planted in good soil and well exposed to sun and air. One of the best is *Iberis semper-virens*, producing long racemes of pure white flowers in spring and summer. This is a truly handsome perennial. *I. semperflorens* will flower in the autumn, and its rather large white flowers are sweet scented. The *I. gibraltaria* with pinkish flowers is very pretty in the early spring.—J. D. E.

—The perennial *Candytufts* may be propagated by division, by cuttings and from seeds, but some of the varieties produce seed sparingly. Cuttings should be placed under glass. I have generally been most successful from July to October. It is best to make a special bed and place a thin layer of sand on the top. Keep close and shade. They are rather slow in rooting.—E. H.

3889.—Lilies of the Valley not flowering.—They do not like a very sunny position; in fact, I once found the Lily of the Valley in a wild state, and it grew in a shady wood and flowered well; but as they have flowered in previous years and have not done so this year, it is possible that they require to be replanted in fresh soil by digging up and parting out the plants. A dressing of shert manure over the plants is also beneficial when they start into growth. The plants should not be disturbed until the leaves die down, and they may be lifted and replanted any time between that and the time for starting to grow again.—J. D. E.

—Lily of the Valley in many places, where growing in sunny spots, have not flowered this season. The flowers died off with the heat and drought. Abundance of water and a little shade might have saved them. Lily of the Valley does best under a thin shade of foliage in the woods. If grown in the sunshine they must have plenty of water in a dry time.—E. H.

—The plants are doubtless behaving thus, because they are too crowded, and want lifting. The best season of the year to lift Lilies of the Valley is the early autumn, as then the leaves have decayed, and the clumps may be separated in single crowns. The Lily of the Valley requires

We should much prefer lifting and replanting than to merely thinning out the crowns, as the plants evidently need a fresh site. This is such a sweet flower that it is worth a little care to produce fine spikes.—C. T.

—A sunny position is not the best for these plants, but the probable cause of the want of flowers this year was insufficient moisture when the buds were swelling. I watered mine with a large can with the rose off as soon as the buds appeared and had a grand show of bloom as usual.—A. G. BURLER.

3879.—Lawn tennis court.—It is not possible to tell you what it will cost to make a tennis court of either of the materials you mention. In some places a suitable gravel would be very expensive, and cinders are not always readily obtainable. Preference should, however, be given to gravel, because of its making a firmer and clearer surface. If your ground is naturally well drained a depth of 7 inches of gravel will be enough. The bottom layer may be 4 inches in thickness, and the material may be much coarser; on the surface there should be 1 inch in thickness of fine sifted gravel. If your ground is level it will be comparatively a light job, but if you have to excavate, or to raise any part, the labour will be considerable, especially in the latter case, when the new moved earth will require well ramming as the work proceeds. As the comfort of the court depends mainly on the surface drying quickly in the winter, you must first put in a drain through the centre, if the sand is of a retentive character. You must also make provision for the surface-water to readily pass away by providing gratings and drains to conduct it to the drain first laid. Correct players, I find, do not like the ground to fall very much, with the object of quickly getting rid of the surface water; when that is the case I allow a 2-inch fall from the centre to each end. If the fall is to extend the whole length of the court it need not be more than 3 inches, which is ample if the surface is kept in good order.—J. C. C.

3878.—Calceolaria rugosa.—This is one of the *Calceolarias* used for bedding. It is a shrubby species, and has also been grown under the name of *C. integrifolia*, under which name it is figured in the "Botanical Register," 744. It is usually propagated by cuttings, but if seed can be obtained it is easy to get up a stock in that way. There are other species used as bedding plants with herbaceous stems. The pretty *C. amplexicaulis* is a beautiful, dwarf, yellow species, well adapted for this purpose,

but there are other bedders, mostly hybrids, of *C. rugosa* and *C. amplexicaulis*. There is also *C. oorymbosa*, which will continue to flower all through the summer and autumn months.—J. D. E.

3883.—Doronicums.—Yes; *D. austriacum* is the species, *D. Harpur-Crewe* being an improved variety of the same. It is one of the very best spring-flowering plants we have, and the flowers last a long time, both on the plant and in a cut state. *Doronicums* are hardy herbaceous perennials, and are easily cultivated in any ordinary garden soil; therefore, few hints are needed. It is well to transplant in the autumn; you will then have a fine show of bloom the following spring. If a few are moved early in June, after the flowers are well over, you will secure a second crop of considerable quantity; but this weakens them somewhat for next spring's flowering.—P. U.

—The variety *D. Harpur-Crewe* is different from *D. austriacum*; but it can be obtained at any nursery where florists' flowers and herbaceous plants are sold. *Doronicum Harpur-Crewe* is the same thing as *D. plantagineum excelsum*. *D. Pardalianche*, *D. Columae*, and *D. alticum* should also be grown. No plants are easier to cultivate in ordinary garden soil, and they increase at a very rapid rate. The plants should be dug up every second year, and be propagated by division.—J. D. E.

—*D. austriacum* is a neater and dwarfier plant than *D. Harpur-Crewe* (*plantagineum excelsum*), but otherwise very similar—I mean as regards the colour, &c., of the flowers. The latter often grows 3 feet in height, while *D. austriacum* seldom exceeds 18 inches, and is of a more tufted and spreading habit of growth. Most of the *Doronicums* grow freely in any fairly good garden soil. *D. Harpur-Crewe* and others luxuriate here in very stiff clayey loam, and flower profusely, but I daresay that in a more free and mellow material they would become finer still.—B. C. R.

—There is much similarity between them, but the *Harpur-Crewe* variety is later in blooming, if anything, and is a first-class plant. It is also, to me, a more robust kind, the flowers being large, well chaped, and produced with great freedom, whilst as regards increase, it may be soon made to double itself. The *Doronicum* produces good clumps, and it is a very easy matter to divide the stools, the best season being the early autumn. All of this class make vigorous growth, and in ordinary gardens, even where the soil and position are not very good, the plant will thrive well, making gay masses of colour in spring and early summer. I have seen this spring some splendid beds of *D. Clusi*, the flowers a perfect and welcome mass of colour thus early in the season. They may also be naturalised with good effect, as they are of a thoroughly hardy nature. *D. austriacum* is one of the best of the family, a good garden plant, free and vigorous; and *D. caucasicum* may also be mentioned; whilst a bold, showy form is *D. plantagineum excelsum*. It may be mentioned also that plants lifted and potted make a gay show in the greenhouse earlier than those in the open, and large quantities are grown in this way also for cutting, as the flowers are much like those of the Yellow Marguerite. The variety *Harpur-Crewe* is very useful for decoration, and should be lifted for greenhouse decoration and grown also in the border.—C. T.

—The variety *Harpur-Crewe* has simply larger flowers than *austriacum*, the latter being the type. Why not grow both? The variety *Pardalianche* is later in opening its flowers, which are also smaller, but the colour, old-gold, is very pleasing.—B. P.

3880.—Campanula pyramidalis, &c.—The Chimney Bell flower, as this *Campanula* is often called, is perfectly hardy and useful for flowering in the herbaceous border, and also in pots in the greenhouse. Seed should be sown in the open ground at the end of May, putting out the plants where to flower when large enough. Not during the current year will they flower, but the next. For pot culture select the strongest plants from the same sown seeds, placing them in 8-inch pots in a compost of three parts loam to one part of horse-manure, standing them in a cold frame for a few days until they have recovered from the check of removal. A sunny position out-of-doors will suit them best, afterwards removing them to the frame during the winter. When the pots are full of roots shift the plants into larger, the

strongest into those 11 inches in diameter, the smaller size less. Copious supplies of liquid manure will be an advantage when the pots are full of roots in which they are to flower. A light, airy greenhouse is the best site for them when the blossoms are expanding. Although the flowers open very well out-of-doors, yet they are liable to be injured by rain and wind; still, those persons without the luxury of a greenhouse can successfully cultivate this Campanula. In the place of the cold frame for sheltering the plants during the winter, plunge the pots in ashes or Cocoa-nut-fibre refuse. Although this is a perennial, it is a good plan to sow a pinch of seed every other year; the roots lose their vitality after two seasons' flowering. *Lophospermum scandens* should be treated as a half-hardy annual—that is, sown in small pots in March and shifted on into large when well rooted, using sandy soil, in a gentle hot-bed, gradually hardening off and planting outside in a warm, sunny position when all danger from frost has passed. Without the aid of glass this is a delicate subject to cultivate.—S. P.

— This is a good border plant. It is strong in growth, and the flowers are produced thickly on the tall, handsome stems. A good specimen in the border is a fine picture in the summer months. It likes a shady position, and is best treated as a perennial. It is a very fine plant also for the conservatory, and if you have young exemplars, give them careful attention, keeping the soil moderately moist. If the seed of your plants was raised in the spring, they will be making headway, and when properly established may be shifted into 4-inch pots for the winter. Old plants will need as they come into flower a little liquid-manure, which is very helpful as the flower-spikes make progress. Those plants raised last year, if the pots are full of roots, should be sifted, and a fine display may be looked for next season. Seed sown in the spring will produce good plants the following year if they are well looked after; but often the finest results come from the plants the next season. During the winter they may be kept in a cold frame, and it is important not to induce a gross growth by an unduly rich soil or over-feeding. A group of this Bell-flower is very beautiful, the flowers either blue or white, and they are produced on tall stems. A good display is kept up over a long season, as they open up the stem, and thus continue long in beauty. Good pot specimens may be placed out on terraces, corridors, halls, besides the conservatory, with excellent result. There is a variety named *compacta*, which, whilst preserving all the good qualities of the type, is much more compact in growth. It is well suited for pot culture. *Lophospermum scandens* is a climber, and will succeed well in the open in the summer months, giving variety to the garden. It is charming when rambling over a tree-stump, but likes a warm, sunny spot. You may raise seeds in spring in heat, like other tender things, and if the situation is at all cold, it is better not to trust it in the open in the winter, but give protection of a greenhouse.—C. T.

— This might, I suppose, be classed as a hardy perennial, but it is generally grown in pots in a cold frame till large enough to plant out or pot on for the conservatory. *Lophospermum scandens* is a greenhouse climber, or it may be raised from seeds annually and treated as an annual, but it is better to grow a plant or two in the greenhouse and strike a few cuttings early in spring for outdoor plants. The plants I raised are earlier and usually flower very freely. I have used this largely for filling round the edges of large baskets on the lawn, for which purpose it is very effective.—E. H.

— This Campanula is quite hardy, but as the seed is very fine the best way to treat it is to sow in well-drained boxes of sandy loam in a frame, from April to June, to flower the next season. Where the soil of the garden is light and well drained the seedlings may be pricked out into a nursery-bed when large enough, and finally be planted out where they are to bloom in the autumn; but if it is heavy, damp, or cold it is better to pot the plants singly, winter them under glass, and plant out in March. They also succeed capitally under pot culture, and flower beautifully in 7-inch to 9-inch pots. *Lophospermum scandens* is a half-hardy climber, with tuberous roots. The seed should be sown in March or April in a hot-bed, or in May in the

greenhouse, and the seedlings be pricked off and potted as they come large enough. Winter them in a frost-proof place, and plant out in May in rich, mellow soil and a sunny position. Plants from seed sown in February in heat frequently bloom the same season, but, of course, they do not grow very large the first year. The tubers may be safely left for the winter in the ground at the foot of a warm wall, where the soil is moderately light; but it is as well to cover them with a foot of ashes or Cocoa-nut-fibre before frost sets in.—B. C. R.

3877.—**American Bellbine or Bind-weed.**—This is by no means the same as our Wild *Convolvulus* as regards colour. It is semi-double, of rosette shape, and of a soft rose colour. But it is a species of our common and troublesome weed; *Calylegia spinnica* incarnata is its full and correct name. It is a native of North America, and when once established in our gardens is almost as troublesome as our common species. I cannot recommend "J. K." to plant it unless he can keep it confined to one spot. This is difficult, because it spreads so freely and persistently.—P. U.

3829.—**French Cannas.**—These varieties usually grow between 2 feet and 3 feet in height—at least, those mentioned—but you must remember that the older type of *Canna* attained much greater height. The dwarf varieties—especially when young—are very charming in pots, as one may judge from the plants at exhibitions. If they are grown in a cool greenhouse during the summer, like such things as the *Fuchsia*, they will flower well in July, and if more heat can be given than that of an ordinary greenhouse flowers will be produced during the winter. They are splendid things to bloom in the greenhouse in late summer, and may be planted out with every prospect of success. The great point to bear in mind when growing the plants in pots is to feed them well and use for soil loam mixed with well-decayed manure, whilst when the pots are becoming full of roots liquid-manure occasionally will go much to promote strong growth and a free display of flowers. The tall plants that we used to use in sub-tropical beds were taken up when the frost had cut the leaves down and stored away like Dahlias. They were divided in spring and started in gentle warmth. No doubt the varieties named will be sufficient for you, and they have flowers that vary greatly in colour. The more effective are the deep self kinds. If your plants are in the greenhouse now give them plenty of air to keep the growth stocky, and when the flowering time approaches feed with liquid-manure giving

early spring divide them singly and then pot them, putting them where they may get a genial warmth to start them. When they made sufficient progress repot them, and before planting out in the open keep them in a cold frame, then exposing them altogether; they are then well hardened. The dwarf kinds are very fine for beds.—C. T.

FERNS.

HARDY FERNERIES.

A HARDY fernery is one of the most delightful features one can have in a garden, but we do not always find a garden provided with one, even though there is a shady nook on the spot which one could turn into a Fern paradise with very little trouble or expense. It is useless attempting a hardy fernery in an unsuitable spot. Ferns are essentially shade lovers, and shade they must have if they are to be grown successfully. But if one has not a shady wood, a snug corner where partial or complete shade is afforded by wall, building, or tree, will be suitable for the cultivation of Ferns. A well-stocked fernery reveals at a glance what abundant variety exists in hardy Ferns alone. Not only can we grow British Ferns out-of-doors, but, also, all the European sorts, North America—which is peculiarly rich in Ferns—Japan, and China, have likewise contributed to our outdoor Ferneries, and even from New Zealand we have some of the most beautiful hardy Ferns that can be grown, an instance of which is afforded by the elegant *Hypolepis millefolium*, which is only just becoming well known as a hardy Fern. The fronds are finely divided, and grow from a foot to 18 inches high. I have seen a mass of it quite 6 feet in diameter, and its creeping roots spreading in all directions. The illustration on page 190 shows what capital plants hardy Ferns make for a town garden. Indeed, nothing is superior to the Male Fern (*Lastrea Filix-mas*) for smoky localities. G.

ROSES.

ROSE LAMARQUE IN MADEIRA.

PROBABLY every beautiful Rose has some place where it is best. Rose lovers, no doubt, see charming instances of where their favourites do well. Of all the Roses I have ever seen the one that has struck me as the most wonderful in its graceful luxuriance is *Lamarque*, in Madeira. Other Roses do well in the same favoured island, particularly *Cloth of Gold*, of which I

Rose "Lamarque" in Madeira. Engraved from a photograph sent by Mrs. Bridson.

mind doses at first. If you wish for flowers in the winter give more heat than the greenhouse; if to be planted out in the garden the time for this work is early June, and they must be gradually hardened so as to withstand the winter. The soil must be fairly rich, and during the summer, if the weather is dry, give plenty of water. When the clumps are large in

remember a wonderful covered way in an English lady's garden, with the Blue *Kennedy* running up through it, and such flowers as I have never seen in England. But *Lamarque*, which I think the Rose of all White Roses, was everywhere in the island, running over cottage walls and hedges. Great numbers of its flowers were brought to the markets. Some bushes

were pruned hard, while others were in full bearing. One might see a fountain of lovely blooms coming out of a Pepper tree, and in some neighbouring trees a lot of black stems pruned hard, looking like Vines, which on enquiry were found to be *Lamarque* pruned and at rest, while other bushes were in full luxuriance of growth. Of course, that could only happen in Madeira and like countries. But it is strange how seldom one sees this fine Rose well done in England. Our country—at least, a large area of it—is quite good enough for it. On south walls of houses, on heavy soils at least, its great heads of lovely flowers are delightful. R.

SEASONABLE WORK AMONG ROSES.

DURING the past two weeks we have been favoured with a few welcome showers. This has brought Roses on space, and they need a considerable amount of attention from now onwards. Sticks must be placed to dwarf maiden plants, and their growths secured as soon as possible. A little thought should be had in sticking Roses. For instance, a 2 feet stick will do very well for such short varieties as *Baroness Rothschild*, *Etienna Levet*, and *Captain Christy*; also for the short Teas, like *Senvenir d'Elise Yarden*, *Catherine Mermet*, and *Niphetos*. But it would be folly to use as short a size for *Gabrielle Lulzet* and *Ulrich Brunner* among the H. Perpetuals, or for the climbers among Teas and Noisettes. In the majority of cases, my readers who have worked stocks of their own will be aware of the strength of growth their varieties attain. If not, let them refer to any Rose catalogue, and they will almost always see the habit of growth specified. With maiden standards it is much best to use a stake of sufficient length to answer the double purpose of supporting the stem and young Rose growth at the same time. Roses, especially these open walls, are very early this year, and in southern localities our walls and fences are covered with bloom almost as much as is generally the case by the end of June. I have already cut *General Jacqueminot* from maiden plants; but the bulk of my H. Perpetuals in the open are much less forward in proportion to the Teas and Noisettes. It is well to keep the surface soil moved with a hoe. I find this conducive to healthy and clean foliage. Unless Roses carry clean foliage, they cannot possibly be in such a healthy state as is desirable. Clean and healthy foliage is a very pleasing sight in itself, independent of any bloom. If you have a few strong growing plants on a wall that are in full and rampant growth, it is not well to allow them to check from want of a few cans of water at this time. One, or at most two, thorough soakings will be of immense benefit now. Walls absorb a great deal of moisture. Besides this, I always plant the strongest and most succulent growers in such a position, and during a dry season like the present they often really need a little assistance. If we can secure good and strong growth now, we are almost certain to get it well matured early in the winter. This will mean greater immunity from frost, and a good crop of flowers next spring.

INSECTS.—Many queries are now falling in as to how is the best way to get rid of these. Green-fly is by far the most prevalent. This is very easily removed if one would but commence in time, and put sufficient vigour behind the eringers. I do not mean that the solution should be applied in one steady and strong jet. It is much better to make short and sharp strokes of the piston. This will cause correspondingly short and sharp jets of insecticide. By using it in this style, the solution goes much further and is more effectual. Use it freely, making certain that every portion of wood and foliage is brought into contact with the mixture. It is just the same here as in watering; the job once done thoroughly is more beneficial, less laborious, and cheaper than two or three half applications. It is not necessary to always use an insecticide. If soft water be used freely, and with a sufficient vigour, it will often answer the purpose remarkably well, and cannot possibly do any harm.

OWN-ROOT ROSES.—These may now be struck from short growths of Teas and Noisettes under glass. Three-parts ripened wood should be chosen, and firmly inserted in a light and sandy compost. They should be well watered at first,

and kept close until rooted. This will usually occupy from six weeks to two months.

BUDDING.—Stocks intended for working this summer must now be frequently looked over, especially the standard or hodge Briers. All side-growths and suckers, except the two or three needed for the buds, must be removed as soon as they form. It is best to cut them off close to the stem at once. Unless you do this, they are very apt to form and push out several more shoots from around the base of the first one. Owing to the remarkably dry spring, the majority of Brier-beds present a woeful appearance. My own do not contain more than 7 to 10 per cent. of survivals, and I knew of several equally as bad. Where one had a few Briers left over from last year, or where the buds failed to grow, they cannot do better than insert some desirable variety at once, obtaining their buds from plants under glass. These will now be carrying some growth in prime condition for working from. Teas especially produce very sound buds under glass. If the old Briers be left too long they get much too coarse for the successful working of any but the very strongest growing Teas; and, unfortunately, it is not these which fail to take, nearly as much as those of weak and medium growth. A few of our finest Teas are difficult to propagate, both as regards securing suitable buds, and also their living when they have been obtained. *Oleopatra*, *Senvenir d'Elise Yarden*, and *Comtesse de Nadailac* may be cited as examples. These and similar kinds produce good wood under glass. P. U.

A few good new Roses.—A very beautiful new Rose is *Turner's Crimson Rambler*, which has been shown on several occasions of late at the leading exhibitions. The plants are of strong growth, and the flowers produced freely, perfectly double, and intense crimson in colour. It is a Rose for small as well as large gardens, remarkably vigorous, and a most worthy addition to the *Polyanthes*. Two charming tea-scented varieties are *Medea* and *Corinna*, the former having very delicate lemon-yellow flowers, a clear and tender shade, whilst the plant is of strong growth as far as I have seen it. *Corinna* is another good Tea-scented Rose, the flowers variously coloured, yellow touched with rose, a number of tints melting one into the other, a charming gradation of tones. A hybrid Tea-scented Rose is a delightful button-hole Rose, the flowers very neatly shaped, yellow, with the petals tinged with a carmine shade, the fragrance very sweet. This will, I think, become a popular variety, especially for cutting, the flowers so neat and charming in colour. A good and useful Rose is *Pink Rover*, which is a half climbing kind, the flowers very delicate pink, deepening in the centre, full, and sweetly scented. It is free, and will cover quickly dwarf fences and pillars, whilst it blooms over a long season, spreading abroad a sweet fragrance. *Sappho* is likely to prove a useful variety, the growth being very vigorous, and the flowers are of pleasing colour, large, full, of globular shape, fawn, shaded with yellow, and sweetly scented. *Spenser* is a good Rose. It has very large flowers, full, broad, and of the *Merveille de Lyon* type. Unfortunately it is scentless, and I think, and others will doubtlessly agree with me, that a scentless Rose is not of great value. I think that fragrance is one of the most precious virtues of the flower. *Spenser* is a good exhibition Rose, large, and pink in the centre, the outer petals shading to white. The *Bourbon* variety, *Mrs. Paul*, is comparatively new, the flowers fragrant and very large, the fine petals white, touched with rose. It is very free, vigorous, and in all respects a thoroughly good garden Rose, whilst it is of interest as possibly the forerunner of a new type of *Bourbon* Rose. There are many other new varieties as *Clio*, *Zenobia*, a new *Moss* kind, and others which will be noted when I know more about them. —C. T.

3897.—Roses for a wall.—As you have a *Gloire de Dijon*, I would advise either *Cheshunt Hybrid* or *Reine Marie Henriettes* as a contrast; both of these are red, and equally as free as the old *Gloire*. In your warm locality, too, *Maréchal Niel* (yellow) should do well in each an aspect—in fact, any climber should thrive with you. Six more of the best are: *William Allen Richardson* (orange and yellow), *Climbing Niphetos* (white), *Climbing Perle des Jardins*

(deep-yellow), *Mme. Chanvry* (salmon and buff, with deep-orange), *Bouquet d'Or* (a deep-coloured *Oleire* de *Dijon*), and *L'Idéal* (orange, salmon, and metallic-red). On your greenhouse wall plant either of the above possessing the colour you most desire. The following are twelve good pot Roses for your purpose; all are very choice: *Comtesse de Nadailac* (coppery-yellow and peach), *Oleopatra* (rosy-flesh and cream), *Edith Gifford* (white, flash centre), *La Boule d'Or* (golden-yellow), *The Bride* (white, grand), *Mme. de Watteville* (cream, rosy edgings), *Souvenir d'Elise Yarden* (cream), *Luciole* (rose, coppery-yellow), *Sunset* (apricot and yellow), *Ernest Metz* (deep carmine-rose), *Angustine Grinoisean* (bluish-white), and *Franceses Krüger* (salmon and apricot). —P. U.

— *William Allan Richardson* (apricot colour), *Lamarque* (white), *L'Idéal* (light-yellow), and *Waltham Chamber No. 1* (red), are four good and distinct climbing Roses for your purpose. For training against the wall in the greenhouse *Maréchal Niel* will do admirably, if the light is not excluded from it. Six good Teas for pots may include *Comtesse de Felkestone*, *Catherine Mermet*, *The Bride*, *Etoile de Lyon*, *Luciole*, and *Mme. Falcott*. —J. C. C.

3894.—A leaky pond.—It is not many weeks since I gave some brief instructions in GARDENING how to puddle a pond in reply to a question, in which I distinctly stated that unless the work was thoroughly well done it would not be satisfactory. Year after year proves that I was right; you erred in not working the clay properly. My instructions were to get lumps of clay and kneed them on a firm platform as a baker does his dough, so that each lump will readily unite with that previously laid down. Seven inches of clay is none too thick, but it will be enough if you thoroughly prepare it, and take greater pains in working it together in its bed; a wooden mallet is a capital tool to use when preparing each lump. This and a thick flagstone, with sufficient water to well moisten the clay, will enable you to prepare the clay in a proper manner. As the work proceeds keep the surface damp, and if the weather is very hot and dry a little shade from old sacks or a mat is desirable until the water can be let in. —J. C. C.

— Of course, the puddling was not properly done. An account was recently published in GARDENING of the proper manner in which to puddle a pond; but the quickest plan to make sure of your work is to coat it with 2 inches or 3 inches of Portland cement, and puddle over that if you like. —A. G. BUTLER.

3886.—Substitute for rotten manure.—There could not be a better substitute for rotten manure than fresh horse-droppings; as it seems to be required for making manure-water, the fresh material is better than the decayed for that purpose. Indeed, for all purposes fresh manure is the best. Rotten manure that has been produced by being over-heated in a big heap is of but little value, as the best of its fertilizing properties have been destroyed by over-fermentation. The best manure for heavy soil is fresh stable-manure, with the greater portion of the straw shaken out of it. —J. D. E.

— For pot plants generally, and *Palms*, etc., in particular, decayed manure is by no means a necessary ingredient of the soil. Some good leaf-mould or half rotten spent Hops will answer the purpose quite as well, or better, and extra nutriment can be supplied as necessary, when the pots are full of roots, by means of liquid stimulants of various kinds. Some growers of *Fuchsias* and other quick-growing plants use nearly fresh horse-droppings, after drying them thoroughly in the sun, as part of the compost, and even when employed in liquid form it is better to dry the droppings partly at least before steeping them. —B. C. R.

— Fresh horse-droppings may be used to make liquid-manure. The best way to do this is to tie it up in an old bag and sink the bag of manure in a tub of water. Dilute the liquid considerably. For most things it will be strong enough if a quart or so from the liquid-manure tub is placed in a three-gallon can, and the can filled up with plain water. —E. H.

— Your statement is a singular one. Surely you can find a liquid yard or so in which to steep up your horse-droppings until rotten. Meanwhile, you must perform use fresh manure, which though not so good, certainly better than none at all. —A. G. BUTLER.

TREES AND SHRUBS.

CLIMBERS ON TREES.

SOME people say climbers on trees are injurious and should never be allowed. In the case of young trees this remark holds good, but in those trees that have seen their best days climbers are admissible. At Syon House, Brentford, I have often noticed that many of the old trees are so treated, and they are lovely objects in the spring and summer months when covered with *Almée Vibert* Roses and other old, yet valued, climbers. In the autumn the contrast of colour of the foliage of Ivy and Virginian Creeper is beautiful. *Aristolochia Siphocampylus* makes a charming plant for climbing over trees when a heavy covering is wanted, while the *Jasmine* is suitable for dwarf trees. One of the most effective is the old *Clematis vitalba*. At Syon in some cases it reaches a height of 40 feet or 50 feet, and during the autumn months the effect is charming. *Clematis montana* is also useful in sheltered places, and when others of a different colour are mixed with it they produce

material when planting, as often the soil around old trees is much impoverished and will not support the creepers. As little training should be done as possible, only small iron racks, not wall nails, or a little dark coloured copper wire placed round the trees to support the growths being used. The illustration we here give shows an old Elder tree, ever and among the branches of which have been allowed to ramble Ivy and Climbing Roses.

Two good Mock Oranges.—Two very charming shrubs for small gardens are *Philadelphus microphyllus* and *P. Lemoinei*, Philadelphia being the botanical name for the Mock Oranges. The former makes quite a bush, and is far less unruly than the more rampant kinds, which require much larger space to develop properly. It does not grow 3 feet in height, and the leaves are small, not unlike those of a Myrtle in character, whilst the flowers are also small, pure white, and borne with great freedom on the slender shoots, and they are very sweetly scented. This species is of comparatively recent introduction, having been brought

phyllys if only one kind is required, and it is well worth planting. I make a note of these fine kinds as they are in flower, and it is when the thing are in bloom that they should be noted for future planting. One knows then what to expect.—V. C.

Chinese Snowball tree.—This is a Guelder Rose, not the graceful tree or shrub, whichever one is pleased to call it, so much planted in gardens, but a Chinese species which is of a very different character. It is a thoroughly good garden shrub, and is not so well known as it deserves to be, the growth spreading out and dwarf. It blooms with remarkable freedom, and the flowers are like those of the Guelder Rose, and stand the branches so that in early June the deep green wrinkled leaves are almost hidden. This shrub likes a rather warm, moderately light soil, and is quite hardy—very suitable for gardens of moderate size. Its freedom of flowering is remarkable. One sees so many common things recommended that note should be made of good shrubs that will give pleasure in early summer with their rich profusion of flower. I have seen *V. pilicatium*

OUR READERS' ILLUSTRATIONS: A picturesque garden. Old Elder-tree covered with Ivy and Climbing Roses. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. John Brier, Junior, Oak Bank, Bollington, near Macclesfield.

a pretty effect. Many of the hardier Clematises, such as *viticella*, *Flammula*, and others may be used for the work. Honeysuckles will also be found suitable, but they require a heavy soil to grow in. Some of the varieties of *Ceanothus* are valuable, and for dwarf trees or poles they are charming. *Vitis hederacea* and *V. heterophylla variegata* are good for the purpose, while *Passiflora cerulea* and the *Hop* have a pretty effect in the autumn months. The most effective plants are Roses, of which there are many that can be used. The *Boursault* Roses and many of the *Noisetto* section are the best. The *Copper Austrian Brier* and *Persian Yellow* do well on trees that have not too much head or top covering. Many of the *Hybrid Perpetuals* do well and cover a large space quickly. The plants require moisture in dry seasons, and if this cannot be attended to, climbers should not be planted on trees, as unless they grow freely and do well they fall in the object they are planted for, and a bare stump is preferable to a miserable creeper. In dry seasons frequent supplies of liquid manure will be found beneficial. It is also important to give the roots some new

from New Mexico in the year 1883, and therefore it is not so well known as many things that have been introduced for a longer period. It is not, of course, a shrub for a crowded shrubbery, and if it is given a place by itself away from other things, the display of flowers in summer will be most pleasing. Few shrubs are prettier, and the growth not being too vigorous, this Mock Orange may be especially recommended for moderate-sized gardens. Ordinary soil will suffice, and it is a mistake to make it too rich, as this results in plenty of growth but few flowers. The only pruning necessary is to remove very weak shoots, not to hack about with a knife recklessly, as is the fashion in some gardens. The other Mock Orange that may be recommended is named *Lemoinei*, and this is a hybrid raised by a celebrated French nurseryman named Lemoine, between *P. microphyllus*, which has just been described, and *P. coronarius*. Like most hybrids, it preserves the general features of both parents. The flowers are very sweetly scented, but not so strong as those of the former. The odour characteristic of many of the Mock Oranges, and the flowers are small and of the palest white. I should choose *P. micro-*

in a few gardens, and it is getting better known, but it should become still more common.—T.

The Rose Acacia.—It is difficult to know why certain trees, beautiful in every way, and not troublesome to grow well, are neglected when many common things are present everywhere. There are few more beautiful trees than the *Rose Acacia*, botanically known as *Rohinia hispida*, and it is exactly the kind of tree for a small garden, as it is dwarf in growth, has graceful, *Acacia*-like leafage, and blooms profusely in early summer. I was noticing in late May several trees in a small villa garden a few miles from London, completely smothered with the rose-colored flowers, but it is not often one finds the tree in such places. It is very hardy, and the only thing to guard against is the wind, which, when the tree is much exposed, breaks the brittle branches. For every garden, even where the soil is only partly good, the *Rose Acacia* is adapted, and it should be noted as one of the things to plant next autumn.—C. T.

Ivy and Grass.—The fault of out-lying Ivy is that it takes longer to become green again, having to make a second growth,

ORIGINAL FROM THE LIBRARY OF THE UNIVERSITY OF URBANA-CHAMPAIGN

which is not so vigorous as the first. It is better, however, to cut it now than not at all. Should the weather remain dry, give the roots abundant supplies of water, which will hasten on the growth. Nothing can be done to make the Grass grow close to the stem of the Oak-tree where the outer branches hang low, excluding the light from its base. Why not lay a few fresh turves every year?—those would keep green for one year. Or plant the space with Ivy; this makes a neat and green carpet, and is always pleasing to look at under trees.—S. P.

—As you have every appliance ready you may clip the Ivy now, but March is the best month, and it will not be very eighty now; still, in your case you may proceed with the work, and the shears will soon effect the desired reformation. Grass will not grow round the base of an Oak-tree—at least, very little, and Grass is never satisfactory further away from the trunk. Why not try a small-leaved Ivy, pegging down the shoots on the soil, and through the summer months helping the Ivy to become established by occasional supplies of water? It will get established in time, and make a nice green surface. Very few things will live under the dense shade of trees, but Ivy is as good as anything that may be recommended for the purpose.—C. T.

3892.—**Creeper for a wall.**—By far the best creeper for your purpose is *Ampelopsis Veitchii*, a fast-growing and miniature form of the Virginian Creeper. It clings most tenaciously to any surface (even glass), and will soon cover any space. Plant now from pots, and afford them a little drainage, so that they have a good start this season. The *Ampelopsis* is not evergreen, but it comes into growth very early, and drops its leaves late. All through the early part of the year it is a beautiful light-green, changing to brown, bronze, rose, and even scarlet towards the autumn. At this time it is one of our most showy subjects. It is hardy, and will thrive in any position.—P. U.

—A good creeper for a wall is *Veitch's Virginian Creeper* (*Ampelopsis Veitchii*), which will, after it has once got established, quickly make headway and cling closely to the wall without the need of shreds or nails. You could also have a good quickly-growing Ivy, such as *Emerald Gem*, or *Clematis montana*; but that will need support, unless it can cling to some gable or ledge. I should choose the Virginian Creeper, which is a quick grower, and plants may be put in even now from pots. You get a fine surface of green in summer, and with the approach of autumn the leaves change to fine colours.—C. T.

—Only Ivy and *Ampelopsis Veitchii* will cling to a wall without support. Both are fast-growing subjects, the latter, however, is deciduous, which would be useless during the winter. If this is important I should advise that Irish Ivy be employed. Procure strong plants and treat them well in the matter of good soil and abundance of water at the roots during dry weather. Growth under such conditions will be made then at the rate of 4 feet yearly.—S. P.

—If you want a plant to cover the wall in the summer only you cannot do better than put in *Ampelopsis*; but if you wish your wall to look green also in the winter get a plant of the small Wood Ivy; the latter, if liberally treated when put in, will soon settle into rapid growth.—A. G. BURTON.

—Plant *Ampelopsis Veitchii*. If strong plants are obtained in pots and set out at once some progress will be made during the summer.—K. H.

3897.—**Oleanders, &c.**—I would advise "Steinten" to wait at least another month before placing those and *Oenistias* out-of-doors. For some seasons past we have had cold weather and actual frosts after this date. Do not turn them out of pots, but prepare a place, throw down a little soil to prevent worms from entering the pots, and then plunge them in ashes or any other handy material. Plants in pots, having the whole of their roots confined, must be carefully looked after as regards water when plunged out-of-doors.—P. U.

—Oleanders are better kept under glass altogether until they have flowered, and even after that if they are at all weakly. These plants like more heat than some people seem to think necessary. They also like a shady part of the greenhouse in hot weather. Still be early yet to put *Azaleas* out-of-doors. They should

be kept under glass until they have formed their flower-buds, which those that have flowered late cannot do for another two months longer. *Genietes* and *Myrtles* may be placed in the open air at once, if they are given a warm position. Such plants as you mention should not be taken out of their pots, and only one-third of the depth of the pots should be buried in a bed of coal-ashes.—J. C. C.

—Oleanders, *Genietes*, and *Myrtles* may soon with safety be put out-of-doors; but in the case of *Azaleas* it is yet a little early for them. The flower-buds ought to be formed before they go out. This is easily ascertained by feeling the extreme point of each shoot. If the bud is formed a hard substance will be found at the base of the uppermost leaves. All these subjects should not be removed from their pots, but be plunged in ashes. The object of burying the pots is to lessen the labour in watering the plants. The soil does not dry in them nearly so fast when they are plunged as it does when they are standing on the surface. Coal-ashes is the best possible material for plunging the pots in. It is porous, and does not harbour the presence of slugs or worms, which soil does. There is such a risk of worms entering the pots when plunged in soil that this plan should be avoided. Do not crowd the plants; allow each sufficient space to stand clear of its neighbour, so that air may freely pass amongst them, the object being to thoroughly mature the growth.—S. P.

—*Myrtles*, *Oenistias*, and *Oleanders* may be plunged out now. *Azaleas* had better remain under glass a little longer till the wood is getting a bit firm, though in the case of hard-wooded plants generally the sunshine has hastened the ripening considerably, and the plants go out sooner than would be desirable in an ordinary season.—E. H.

—Yes, any of those mentioned may now be safely exposed—that is, supposing them to have been growing in a cool and airy atmosphere previously. But it is only fair to add that unless sufficient growth has already been made this will not take place as rapidly and well in the open air—at least, if the weather is at all dry and warm—as would be the case if the plants were kept for a time under glass. As a rule, such things ought not to be turned outside until sufficient growth has been made indoors. As regards plunging the pots, it is, on the whole, decidedly advisable, particularly where the plants do not receive frequent and regular attention in watering. It saves a lot of watering, and prevents any risk of the roots becoming burnt by the pots getting unduly hot under a strong sun. Plunge them either in ashes, or if in the soil, make the holes tapering, like the pot, and a few inches deeper, leaving a hollow beneath, which will at once prevent worms entering through the drainage-hole, as well as the roots working through, and insure free drainage.—B. C. R.

—The *Azaleas*, *Genietes*, and *Myrtles* may go out in the month of June, but *Oleanders* are likely to get neglected; and if you require a good bloom it would be better to have them under the eye in the house. The other things benefit by being in the open during the summer months, and require chiefly close attention in regard to watering, as in the open in the summer the soil quickly gets dry. Do not take any notice of showers; they only make the surface of the soil damp, and do not really soak the ball. As to position, nothing is better than against a shady wall; they should not be exposed to the full force of the sun, and the *Camellias* will benefit by a few supplies of scot-water. Stand the plants upon a firm bottom of coal-ashes, as these prevent worms from getting into the pots and choking up the drainage. If this becomes out of order the plants will soon get unhealthy. It is not necessary to hurry the pots, nor must the plants be removed from them; simply stand them out as advised. Early in the autumn, before frosts occur, remove them inside. Give the pots a thorough cleaning, and see to those that have worms in them.—C. T.

3750.—**Horshound beer.**—A handful of dried Sage and Burnet, handful of dried Horshound, handful of dried Pennyroyal, handful of dried Marsh Mallows, handful of dried Agropy, two or three Dandelion-roots, two or three Nettle-roots, handful of Hops, 2 lb. of lump sugar, 2 oz. cream of tartar, and two

tablespoonfuls of Mason's Extract of Herbs. Mix all well together, then boil the Herbs in enough water to make 4½ gallons for about an hour, strain off, and when cool enough put a teaspoonful of herm in. Let it work all night. Put it in cask next morning, and when it has done working bang it down and draw off in two or three days. It is better to put a little isinglass in to fine it; and a little burnt sugar to colour it.—C. G. H.

HOUSE & WINDOW GARDENING.

BELL-FLOWERS AS WINDOW PLANTS.

THERE is much sameness in window plants, but there need not be if those who like their windows gay with flowers would grow such things as the Bell-flowers or Campanulas, which are of great beauty thus placed. They do not mind the dry atmosphere of rooms, and even in stuffy cottage windows will bloom freely. I have seen *C. carpatica*, the Carpathian Bell-flower, in splendid bloom in windows, the large pale-blue coloured flowers hiding almost every trace of leafage. There are many varieties of it, *palida*, *alba*, and so forth, but the best are the parent and the pure-white form. It is necessary to keep the plants well watered, but ordinary soil suffices. In windows they get very dry, and a gentle dousing with a syringe or placing them out in soft showers of rain is helpful to them. Perhaps the most useful kind for this purpose is *C. fragilis*. It is not thus named on account of its growth, as it is vigorous, but the flowers are delicate blue in colour, the shoots being covered with them, and they hang down gracefully. It blooms with the greatest freedom, the hanging flower-laden shoots being very pleasing in a window. Then one may choose also *C. gargarica*, which is not as well known as *C. fragilis*, but may be grown well in a window. It is called *C. fragilis* sometimes, but the white plant is bolder. One scarcely wants both kinds, and preference should be given to *C. fragilis*, as this succeeds remarkably well in a hanging basket in the greenhouse or the window. Very suitable for pots is *C. muralis*, called in some catalogues *C. Portenschlagiana*. It is very dwarf, quite a gem amongst Campanulas, the light-green leaves hidden by the delicate blue flowers, and grows very freely. *C. gargarica* blooms in June, and *C. muralis* later, thus maintaining a succession of flowers. The Ligurian Bell-flower (*C. isophylla*) and its variety *alba* are well worthy of note for pots, and may be readily grown in a window. The type has pale-blue flowers, but there is a pure-white form, which is very charming, free, and vigorous. I am surprised it is not more common in gardens; the shoots trailing, and the flowers are comparatively large and of the purest white. When in full beauty few things are more pleasing. This small selection gives considerable variety, and of a class of plants not too common in gardens.—T.

3901.—**An enemy to the Auricula.**—I have never seen this pest upon Auriculas, and hope it will not come near my collection; but by the description of it, there is not much chance of getting rid of it, except by picking the larvae off the plants, and as it rolls up the leaves there will be no difficulty in finding it. I have on several occasions had to deal with a small green caterpillar, and the same species has attacked other collections, and there is nothing for it but hand-picking.—J. D. E.

3898.—**Seeding Pelargoniums.**—The plants ought to have bloomed before this. As a rule, after growing to a certain height the flower-bud is produced with unfailing certainty. I make a sowing almost every year in February or the early part of March, and most of the plants flower by Christmas at the latest, the rest in the following spring. A batch of plants (*Zonais*) from seed sown last July are now in many cases showing the bud. All that is necessary is to keep the seedlings growing quietly on, with plenty of air and sun, avoiding much manure and extreme starvation also. The plants must not be stopped; keep them to one stem.—B. C. R.

—These are the Pelargoniums out to a shady spot where they will flower.—E. H.
—These are the best bloomers. Try cuttings from them, and I think they will do better.—A. G. BURTON.

FRUIT.

FLAVOUR IN PEACHES.

The question of flavour in Peaches and Nectarines is a very important one, and of all fruits grown under glass—Melons which are poorly grown excepted—there is no other kind which is so unpalatable as an insipid Peach. The want of flavour in market Peaches is often very pronounced, but this is principally on account of the baneful practice of gathering the fruits before they are ripe. This is carried to such an extent that they are often quite hard at the time of gathering, and this being so, how can the fruits be expected to be of good flavour? It does not matter how well the fruits may have been grown, if they are gathered before they are well advanced to the final ripening stage, that full, luscious, and vinous flavour so characteristic of a well-grown Peach will be sadly deficient. There certainly appears to be a mistaken notion that for market the fruits must be quite firm when gathered, so as to ensure their safe arrival when carried a distance by rail or road. Some people say if colour is present it matters little about flavour, but I invariably find that where the fruits are well advanced towards the ripening stage they command a higher price and the colour is also more pleasing. It is astonishing the colour Peaches take on during the last twenty-four hours previous to their final gathering, and this alone is well worth waiting for. There is also the additional danger of leaving the fruits too long on the trees before gathering, for when they are allowed to hang too long the flesh is woolly in texture and lacking in juice. The practice of allowing the fruits to drop into nets cannot be too strongly condemned, for when they are so far advanced as to fall the full flavour so desirable will have vanished. The injury alone that the fruits receive is also much against their keeping, for it will be noticed that these net-caught fruits keep but a very short time. I have known such fruits as these to be even sent a long railway journey to London only to arrive at their destination a mass of decay, brought on through their bruised and over-ripe condition.

MISTAKES of this kind generally result in going to the other extreme of gathering too early. I never consider a Peach or Nectarine, especially the latter, fit for gathering until it will part from the tree after being firmly grasped by the hand and given a slight backward pull. A pad of cotton-wool laid in the hand is sometimes used, and if the hand be hard and horny this aid may certainly be of use to prevent injury, but otherwise it is in the way. A practised eye can tell almost at a glance if a Peach is fit for gathering on account of the change of colour near the base of the fruit. Some people also recommend the use of a pair of sharp Grape-sissors for detaching the fruit, but these can only be used occasionally, for if extreme care is not taken far more injury will accrue to the fruit than without their aid. Indeed, the formation of some of the varieties is against their use, for it would be impossible to reach the foot-stalk without injuring the fruit. In gathering Peaches they should be laid in shallow trays over a base of soft paper shavings, with a layer of silver paper over the whole. The fruits when laid on this should be removed to a dry and cool room or cellar, when twelve hours afterwards they will be in condition for use. They will keep well for three days if the position is cool, and I have even kept them a week, but, as previously mentioned, the flavour is more fully developed from twelve to twenty-four hours after gathering. The early morning is also the best part of the day for gathering, as at that time the fruits are cool. The

warm and dry air, are most important. A damp and close atmosphere must be avoided, also overhead syringing when the fruits change for ripening, but inside moisture must not be wholly stopped, as the floors should be damped in the morning and evening during fine weather. A sudden withdrawal of inside moisture would affect the foliage considerably, especially under the strain of a bright sun. The practice of applying liquid-manure to the ripening fruit may also be easily overdone, as I have known the flavour sadly depreciated by this course alone. The application of liquid should be dispensed with at least a fortnight previous to gathering, or rather ripening, a soaking of clear water at this stage being the best. If the surface is littered down with long stable litter at this time, sufficient moisture will be retained in the border to carry the fruits through to their full stage. If a heavy watering is given a few days prior to gathering, it sometimes causes the fruits to part from the tree before their time. H.

OVERCROPPING FRUIT-TREES.

OVERCROPPING is a very great mistake, as it not only renders the fruit of poor quality, but also weakens the tree. I once called upon a gardener who had several vicueries under his care, and the crop hanging was about the heaviest I ever saw, but the quality of the fruit

certain large growers for market who allow their Vines to carry very heavy crops, but at the same time feed heavily. As a rule, these Vines are growing in soil the most suitable for Vines growing, and also in a condition mechanically for receiving abundant supplies of what are termed artificial manures. Again, the rods are not expected to last long, and in the majority of cases the crop is out as soon as fit; consequently the Vines are relieved of the load at once, and they also have a lengthened time in which to recoup their energies. This is quite unlike the majority of cases in private gardens, where the Vines are supposed to last a long time, comparatively speaking, and it behoves those who are in charge to crop the Vines judiciously, especially in the younger stages, the aim being to build up Vines which will be capable of supplying good regular crops for years to come. Occasionally we hear and read of

SENSATIONAL CROPS being taken from very young Vines, but this is no criterion that the practice can be indulged in generally. Neither is it wise to do so. The width apart the rods are growing makes a deal of difference as to what weight of Grapes each should carry. For instance, a Vine with the rods 4 feet apart is able to bring a greater weight of Grapes to maturity than another with the rods 2 feet apart. Taking varieties of Grapes as a whole, where the bunches range from 2 lb. to 3 lb. weight each, a bunch from every other lateral would be an ample crop. A greater weight of Alicante may be brought to maturity on a single rod than, for instance, in the case of one of Black Hamburgh. This latter, although a fair number of ordinary bunches may be produced, will not stand overcropping, that is if the highest finish is desired. As is well known, Muscat of Alexandria and Mrs. Pince's Black Muscat are very impatient of heavy cropping. I never allow a rod of the latter to carry above five or six bunches, but then these are of a very large size. The Vines would have to be in the best possible health to bring even the above number to full perfection, size of berry and colour being taken into account.

PEACHES and Nectarines are often decidedly overcropped. Small fruits either of Peaches or Nectarines are never looked upon with favour. Depth of flesh is lacking, and also lusciousness. As a rule, the larger kinds of Peaches should be thinned down to one to the square foot of surface, 9 inches for smaller kinds. Nectarines may range about 9 inches, and the trees being healthy the fruits will be brought to full perfection either for home use, exhibition, or market. For market it does not pay to produce small fruit even if there is quantity. Figs pay for thinning, especially where they appear too thickly or in clusters, or where there may be danger of the trees casting their fruit, especially the earliest crop. Melons, again, should not be too small. Fruits which will range from about 3 lb. each are of good useful size. I allow our plants to produce from two to four or five fruits each. Plums under glass I also thin. A.

A basket of Peaches.

was poor in the extreme. There were so many Grapes that the gardener did not know what to do with them, and as marketing the surplus was not looked for, there was a considerable quantity on hand. Now if these Vines had only been allowed to carry about a third the number of bunches, the quality would have been higher and more satisfaction would have been given. Very often what appears an ordinary crop grows into a much larger one than the grower anticipated. A grower should be able at thinning time to gauge the weight of the crop the Vines will carry, and at this time out off all superfluous bunches with the exception of one or two extra to a rod, these to be cut off as soon as the bunches have stretched well down and it is seen what the crop is likely to be. It is perfectly useless to overburden the Vines with superfluous bunches, and then at about the colouring stage to come to the conclusion that too many have been left on and commence to cut them off. Certainly lessening the crop at this stage makes the best of the evil, but the principal mischief will have been already done. What should constitute

A FAIR CROP will have to be gauged by the health and general condition of the Vines, length of rod, and so forth. The size of the bunches will also gauge the crop to a certain extent, and also the amount of feeding that they have given. As an argument for heavy cropping, it has been advanced that there are

3893.—Vines bleeding.—“J. S. L.” does not state whether the Vines that bleed are, or are not, under artificial heat; but be this as it may, I should attribute the bleeding to the last pruning being too late with reference to the rising of the sap. The bleeding this year will cease when the leaves are further developed, and next season it may be prevented by pruning at the fall of the leaf, thus giving an interval of some months before the succeeding spring, and time for the pruning-wounds to harden before the rise of the sap.—J. M., *Southants*.

3893.—Mildew on Vines.—I suspect the cause of the Vines being infested with mildew at this early stage is owing to the admission of front air to the house too freely during the time when cold winds have been blowing, or it may be caused by opening the front ventilators too early in the morning, or leaving them open too late in the afternoon. There is nothing so likely to produce mildew on Vines as draughts of cold air. If my surmise is a correct one, I should advise “Bankais” to be more careful in the future, and cease the opening of the front ventilators altogether until the Vines have passed their flowering stage, and the berries have been formed. Keep the atmosphere drier by warming the hot-water pipes, if the house is fitted

TIME of gathering is obviously only one way of securing fruits of well-developed flavour, and other cultural details, such as a circulation of

with any; at the same time admit air through the top ventilators to keep the inside atmosphere in a buoyant state. A temperature by day of 75 degs. with air on is a safe one; if it runs up to 80 degs. during the hottest part of the day no harm will be done, giving a little air at 70 degs., allowing the thermometer to rise with air on. Until the berries are thinned it would not be safe to dust them with sulphur, nor cover the hot-water pipes with it, but the main rods might be painted with it at once, mixing it with water until of the consistency of paint. Sulphur may be scattered about the floor of theinery, and on the border also. When the berries are as large as Peas the whole bunch might be dusted over with sulphur if the attack of mildew is a violent one. The sulphur can afterwards be washed off with water applied through a syringe, if it cannot be blown off.—S. P.

Sulphur is the best specific for mildew; but this parasite ought not to be on the leaves of the Vines before they come into flower, if the border is in good condition, and the Vines, when in a dormant state, were dressed with the usual mixture of soft-soap, sulphur, and Tobacco-liquor. This destroys all the germs of mildew. The sulphur may be dusted on the leaves and stems as soon as the blossoms are set, and it may also be necessary to dust the Grapes, for the mildew attacks the berries as readily as it does the flowers. When mildew makes its attack later it can be destroyed by painting the heated pipes with sulphur when the house is shut up; but this would rust the skin of the berries if done before stoning commenced. Dusting with flowers of sulphur does not cause rust.—J. D. E.

I suppose the mildew is on the foliage, and if not destroyed now it will attack the berries later on. The Vines may be dusted over with sulphur at once, or the sulphur may be mixed with water and syringed over the Vines two or three days in succession. If there is a heating apparatus, light the fire and make the pipes moderately warm, and mix sulphur and skim milk into a thick paint and brush it over the pipes. This and a little more attention to the ventilation, or avoiding cold draughts, will check the mildew; at any rate, this sulphur treatment must be persisted in till the mildew is destroyed. The black sulphur is the best.—E. H.

3383—Treatment of young Vines.—Remove all side shoots, thereby throwing the whole strength into the main stem, which should be encouraged to grow 8 feet long, when the point may be pinched out to induce the lower buds to plump up. Any side shoots afterwards should be pinched in at the first leaf. Presuming the plants are now in 8-inch pots, shift them at once if full of roots into those 10 inches in diameter, using a compost of three parts fibry loam to one part of horse-manure, with the addition of a handful or two of finely ground bones to each pot. Stand the plants in a light position in a temperature not less than 60 degs. by night and 75 degs. by day. Syringe the foliage twice daily with tepid water, and supply the roots freely with moisture as required. When the colour of the bark changes to yellow nearly the whole length, and the growth ceases, give the plants more air to ripen the canes, finally standing the pots out-of-doors at the foot of a south wall, where they may remain during the winter if the pots are covered with litter to prevent the soil and roots being frozen.—S. P.

All the side-shoots should be pinched back to one joint from the main stem, and as soon as another growth pushes out from that, pinch again at the first leaf. The main leading growth will push away more rapidly when the side-shoots are stopped, and the lower growths will soon cease to make any progress. Vines from eyes put in so early as January should grow into fruiting-canoe the same season.—J. D. E.

Stop the side shoots or laterals to one leaf and shift into larger pots as more room is required, using turfy loam and old manure.—E. H.

A note on Strawberries.—British Queen Strawberry is by far the best for flavour of any variety, and now that so many new Strawberries are being raised it is important to bear in mind the quality of the fruit. A big tasteless, wettery Strawberry is not what we want, but good, free-bearing, strong kinds of

the British Queen type, which have fine flavour to recommend them. It seems that there is a prospect of getting some good Strawberries for flavour, as Mr. Allan, head-gardener to Lord Suffield, has raised several kinds that are of the British Queen class. The plants are strong growing, and with handsome fruit of good colour. Empress of India has quite the flavour of British Queen, the fruit of moderate size, of good appearance, and bright-scarlet, the flavour rich and with a pleasant acidity, characteristic of the parent. Lord Suffield is a kind of very good flavour, the flesh deep-red in colour, juicy, and firm. Gunton Park is another promising new Strawberry, the fruits being larger than those of the other kinds, and of bright-scarlet colour, and rich flavour. This is free also, and a thoroughly good garden kind.—V. C.

THE PINK.

This homely flower is in most cottage gardens. An edging of White Pinks is very beautiful, and the simplest outline suffices to gain this interesting and quaint picture. The many charming Pinks of garden have sprung from *Dianthus plumarius*, that, like the Clove Pink, loves to send its roots into old walls. The writer remembers it on Conway Castle, but that is several years ago, and unthinking tourists may have deluged its little tofts in their eagerness to acquire "mementoes." The Pink of garden is hardier than the Carnation, and is subject to fewer diseases. It may be planted in clumps on the borders as an edging to walks, or in any spot to which it is likely to constitute appropriate effect. The soil should be well prepared, whilst in spring they may be top-dressed with well-decayed manure or good loam. For years the "florists' Pink has been frowned upon, and by this Pink I mean those fine-faced kinds that delighted the florists of old. A new love has sprung up for this long-neglected class, and as with the Lavender, a special society has been formed to promote its culture, spreading abroad knowledge of the varieties at command, and encouraging lovers of Pinks to add to their number. There are two classes of florists' Pinks, the purple-faced and the red-faced, and a typical flower should have petals of shell-like shape, smooth, the ground colour white, with bright, decided, and regular tinging. A few of the finest varieties, and the list is necessarily limited, comprise Asot, Lord Lyon, Derby Day, Borard, Jeannette, Modesty, Ethel, Henry Hooper, Empress of India, K. L. Hooper, The Rector, John Bell, and George White, the three first named in particular being very fine border flowers, sweet scented, and useful for cutting. If one is an ardent Pink fancier he will have some of these beautiful faced varieties. They should be grown on a raised bed so as to throw off heavy rains and dispel damp, planted late in September and in the spring top-dressed; it is not necessary to grow them in pots. When the buds appear thin them out judiciously, and scarcely tie the stem to short sticks. The Pink may be propagated by layers or cuttings, sometimes called "pipings," the term, in fact, usually used, but it simply means cuttings. The best time to take them is when the plants are going out of bloom. Use 4-inch pots, crack them well, and fill them with light sandy compost, reserving about half of an inch of space from the margin for sharp silver-sand. Select for cuttings the sturdiest shoots, cut them sharp under a joint, remove the leaves from the space to be inserted in the soil, and about a dozen may be put in each pot. If a little gentle heat can be given to ensure quick rooting so much the better, but they will strike even in a cold frame, taking care to keep the soil moderately moist, and shade them from hot sun. In the course of three weeks or a month they will have rooted, and when of sufficient strength may be planted out in the garden. Even the cold frame may be dispensed with, so that those who have not this luxury may yet grow good Pinks. The cuttings will strike well if a bed of light soil is made up in a sheltered, moderately shady corner in the garden, the cuttings dibbled in and covered with a hand-glass. Keep the glass wiped, so as to dispel damp. The sweet-scented Pink Mrs. Sinkins is very charming, but the celyx splits very much. Those who do not grow Pinks should not think of the faced varieties before the beautiful fragrant old White Pink, which is a precious garden flower.

THE CAUCASIAN SCABIOUS.

This plant is an almost incessant bloomer, its value in the mixed border or on the rockery will be at once apparent. In most gardens we invariably find it under the name of *S. caucasica* var. *amena*, which I believe to be altogether erroneous. *S. amena* is a true species, native, I believe, of Asia Minor, totally distinct, and, judging from dried specimens, in no way deserving of such notice as the subject of our note. In Regel's "Gartenflora," t. 1. 1084 and 1212, we find figures of two varieties or forms of *S. caucasica* called *heterophylla* and *olegus*, and it is to the latter name that the plants grown in English gardens belong. Our plant will be found to differ from typical *S. caucasica* by being more robust and having considerably larger flower-heads. The leaves, too, are not so much divided and the plant is altogether less straggling. Both the type and its varieties have great affinity to the better-known *S. graminifolia*, which is a really pretty plant, and one that could ill be dispensed with for rockwork or flower border. *S. caucasica* and its varieties will be found to differ from the latter by their more erect stems, much larger flowers, broader and less silvery leaves, and in the length of the inner calyx, which in *S. graminifolia* is hardly longer than the outer. *S. caucasica elegans* has the largest flower-heads of any species known to me, and is said to have been first raised by the Leddles from seed received from Mount Caucasus. It may indeed be placed in the front rank of showy and useful hardy perennials, and will be found invaluable for summer and autumn decoration. It will hardly be necessary to say that the Caucasian Scabious should be in every garden. The flowers are well adapted for cutting. They last a long time in water, and the clumps are rarely without flowers from early summer until late autumn; their peculiar soft lilac-blue tint and the ease with which the plant may be grown are all points in favour of its general utility. In a light sandy, not overrich soil this plant is all I have described it. I was, however, not a little surprised to read in the pages of the *Garden* of its almost total failure in localities with heavy damp soils, even in places specially prepared for it to grow in. There seems no way of getting over this difficulty unless by raising a variety with a constitution sufficiently hardy to withstand the damp soil of a heavy clayey soil. Its propagation either by cuttings, division, or seeds is comparatively easy; the two first in spring, the latter in autumn and spring. I suggest spring not because divisions may not be equally successful in autumn, but because of the greater risk of being caught, as we were, in a long spell of hard frost, which completely destroyed them. As a plant for grouping in the wild parts of the garden, *S. caucasica*, on account of its graceful habit, will be found especially suitable; it is easily raised from seed, and may be had in flower, and forms strong tufts the second year. Most of the other perennial Scabious are retained only in botanical collections, but the annuals, such as the well-known *S. atropurpurea* and its numerous varieties, *S. maritima*, *S. palestina*, *S. stellata*, well deserve special attention; of the two latter, although having showy flowers, the seed-heads in autumn are by far the most attractive, stellate in form, and very remarkable on account of their transparency. From a batch of seedlings many well-marked and distinct forms may be obtained. K.

EDGING PLANTS.

There is a wealth of beauty in an edging of a good hardy plant, such as the common Thrift or the London Pride, and by their use the removal of ugly brick-ends, tiles, and other hard, formal obstructions is ensured. The object of a garden is to fill every nook and corner with flowers, and this may be accomplished if forethought is exercised. Instead of hideous tiles or patent edgings, grow flowers, and there is a fairly long list to choose from, comprising Saxifrage, Thrift, Daisies, London Pride, Arabis alba, the rich Blue Gentianella, Cerastium, Stonecrops, Primroses, and Violets. Where good stone can be got, and in many country gardens this is the case, it will make a delightful edging over which Stonecrops and Saxifrage can creep, making a soft velvety-green

carpet, spangled with flowers in the proper reason. Where the rather fastidious *Gentianella* can be coaxed into respectable growth it must have a soft sandstone to grow upon—at least, it succeeds much better under these conditions. Moist, loamy soil suits it well, and when once established will quickly spread, bearing a profusion of its large, tubular, intense blue flowers. Double Daisies are delightful things to establish by a garden path. They form a perfect mat of growth and grow in ordinary soil. It is necessary to take them up occasionally, according to the progress made, and divide the clumps. Few plants are more easily propagated than the Daisy, and the clumps may be lifted in either spring or autumn, putting each little plant into good garden soil. When for edgings they should be fairly close together, so as to quickly form a dense mat. Quite as charming for an edging is the Common Thrift, making an even mat of bright-green, and when the plants are not permitted to go more than three years without division and replanting a gay display of flowers is assured each year. A line of Thrift in bloom is peculiarly beautiful—a perfect carpet of rose colour. There is more than one kind, the best being the deep-rose coloured form, which is more effective than either the white or the Common Thrift. Edgings of hardy plants are sometimes untidy and ragged through neglect. London Pride, unless given reasonable attention, is a poor plant, but when lifted and replanted when the growth has become too dense, the flowers are borne with the greatest freedom, a shimmering mass of pink and white, distinct and pretty. The Mossy Saxifrage is the most suitable, and of both these and the homely Stonecrop one can get several kinds in a comparatively small space. All these edgings present a green and cheerful aspect throughout the year, freshest, perhaps, in winter, when they are a relief to the prevailing bareness, whilst in the summer or the spring, whatever the season of flowering may be, a profusion of bloom adds to the beauty of the plants. C. T.

ORCHIDS.

CYPRIPEDIUM INSICNE.

I AM asked by "Laura Kendall" to say something about this plant and its varieties, and if there is any means of distinguishing the varieties by their foliage? To all of which I must say there is not, for all the forms have foliage alike, plain-green in colour and about a foot in length. There may be some slight difference in the breadth of the leaves of some of the forms as compared with others, but that is nothing, and the safest plan is to tell you that all their foliage is similar, and of a plain-green; but with their flowers it is quite different, because these vary very much, and some of the varieties are very beautiful. Of the old forms, punctatum violaceum, nr, as it is called by our French neighbours, Chantini, is the very best, the breadth of the dorsal sepal, its bold spotting, and the fine pure-white border rendering it very conspicuous. Another nice one is named Maulei, which has the base of the dorsal sepal narrower, the upper portion white, and beautifully spotted with purple; but amongst the newer varieties there are some splendid kinds. These have been mostly introduced by Mr. Sander, of St. Albans, and in the first rank stands the exquisite plant known as C. Sandere, the whole flower being of a soft lemon-yellow, with the dorsal sepal of a pure-white in the upper part. It is one of the most superb flowers in this now numerous members of this genus, but it is still as rare as it is chaste and beautiful, consequently need not be named here. But there are many fine and choice kinds which have bloomed from the same introduction. From amongst other introductions there is the form called Morianum. Eyermani is another beautiful form resembling Sanders very much in general outline. Going into descriptions of the many varieties now to be found of insigne would be of no use, but I will say a little of its cultivation. Now many growers spoil the plant through potting it in such a foolish manner, and through not draining it sufficiently, using for soil good turfy loam two parts, and one of good brown peat, mixed up well, and the plants should be potted below the pot's rim, so that they may

have room enough for a good soaking of water. Now, the treatment is the next thing to be considered. Some grow the plant in a greenhouse, others in the stove; whilst some again succeed well with growing the plant in a cool frame, and all may be practised with success; but if you wish to have these plants in bloom about the month of November or December, they must be grown in stove temperature, but if at a later season a cooler place will suit them well, and, therefore, I advise my readers to select good varieties when in flower, and to grow, say, a dozen or two for succession.

MATT. BRAMBLE.

BRITISH ORCHIS.

I AM in receipt of two kinds of these very beautiful flowers from "Fred. Philipps," asking for their names, and how he shall proceed to grow them? Now you see these beautiful Orchis are given to variations even in a state of nature,

A fine hardy Orchis (*O. foliosa*).

but as they all spring from seed in the first place, this is not to be wondered at. Your 1, 2, 3 are all forms of *O. maculata*, which is popularly known as the Spotted Orchis, the 3 being nearly a white form of the typical form, No. 1, while 2 is a very deep-coloured and beautifully spotted form, reminding one very much of some fine marked variety of the much neglected, but beautiful tropical *Saccolabium*; they, however, do not last so long in full beauty as their tropical relatives, probably through their being more easily fertilised, through insect agency. The other kind is the Purple Orchis (*Orchis masculina*), the leaves spotted with purple-black, and the somewhat lax spikes being furnished with flowers of a reddish-purple of various shades. Now, growing these plants is usually considered a most difficult operation, but I do not think this need be so. I am under the impression that if the tubers are lifted at the proper time, and planted in congenial soil, there is nothing

to render these Orchis difficult or hard to grow. The plants must not be taken up now, for this is more especially the very worst time; but so many never think of these plants, saving when they are to be seen in flower, that they are ruthlessly destroyed through being unearthened just at the very time that they should not be disturbed; but they are worth watching and waiting for to secure them at the proper time. They should be marked with a stout stump or stick, so that they may be dug up when they are at rest. Then, having already prepared a border in accordance with their requirements, they should at once be planted in it, having a care that they are planted at about the same depth as they have been taken from. The following kinds may be grown in a mixture of loam and limestone: *O. masculina*, *O. militaris*, *O. aculeata*, *O. morisii*, and *O. pyramidalis*, whilst the annexed thrive best in a mixture of loam, leaf-mould, and peat, made sandy: *O. latifolia*, *O. laxiflora*, and *O. maculata*. There are many others which require to have the soil made especially for them, and of these are the Bee Orchis (*Ophrys sphegodes*), the Fly Orchis (*O. muscifera*), and the Spider Orchis (*O. aranifera*), all of which require a mixture of chalk or limestone in the soil. Now, I think with these instructions all my friends ought to succeed with these plants. I might add that the borders in which these tubers are planted are better if sown down with Grass, and by advocating this system it may be inferred that I do not believe in them being disturbed with the fork at any time. A very fine hardy, though not native, Orchis is here figured. MATT. BRAMBLE.

ONCIDIUM AMPLIATUM MAJUS.

A FLOWER of a very fine form of this Orchid comes to me from a "London Grower," which he says he has cut from a branched spike, and the plant was sent to him from Trinidad. In reply, I may say that he has done the very thing that is wanted for this species—that is, to keep it moderately moist through the autumn and winter, and in a temperature of about 65 degs., and which does not fall at any time below 60 degs. You see I am not so sure that this plant is indigenous to the Island of Trinidad, but it is somewhat plentiful in Central America, and it is quite possible to have been imported from the last named country to the place whence my friend received it, more especially as in Trinidad they have a fine Botanic Garden, which it has been the special aim of its various directors to enrich. If the plant is now found growing in a wild state it may be as an escape from the gardens. Mind, I do not say this is the case, but it appears to me to be a reasonable inference to draw. The variety of this *Oncidium* named above is far superior to the typical plant, and it is a harder and stronger-growing Orchid, making fine, long, and branching spikes, which are laden with an abundance of rich ochraceous-yellow flowers in front, and at the back China-white, which are about an inch and a half across, thick and fleshy in texture, and which last a good time in full beauty. The tubers are much wrinkled, of a pale shade of green, suffused with purple, and bearing a pair of oblong lanceolate leaves, which are of a good substance, and rich shining green. I have seen many fine examples of this species blooming with Mr. Sander at about this period of the year, and I have observed that Mr. Sander keeps this plant exactly as I did some years ago, when I used to grow this plant so successfully, and, as I have stated at the commencement of this article, the plant I have found to succeed best when grown as a pot-plant, using a good int of crocks for drainage, and raising the plant upon a mound well above the pot's rim in order that the young growths may be secure from being inundated with water. Use for this purpose the fibre from good upland peat, mixing with it about an equal part of chopped Sphagnum Moss, so that it may mix better with the peat-fibre. Press the whole down firmly, and so make all solid and sound, and water well. If the plant cannot have a good exposure to the light, it would be well to run a wire round the pot and hang it up to the sun and light; but it must be borne in mind that the run should not be allowed to fall with its full force upon the leaves and tubers, for the plant likes partial shade. MATT. BRAMBLE.

INDOOR PLANTS.

3884.—**Double Petunias.**—These are easily grown, and very showy when in really good condition. The object should be to have as much bloom as possible and the plants dwarf, with good foliage. A well-grown Double Petunia, when in full blossom, should not be more than 18 inches high from the top of the pot. Some varieties do not reach that height. If the plants measure that much in diameter also they can be considered good specimens. When the plants are 4 inches high the point ought to be pinched out to induce side-shoots to form. These should be treated exactly in the same way when that length. Continue this practice until within two months of the date they are required to be in bloom. Commence early to train the shoots outwards by the aid of small stakes to induce all to grow strongly by providing a fair share of light and air to each. Pots 9 inches in diameter are large enough for the plants to flower in. From 4-inch pots they should be shifted in those 7 inches, and then into the 9 inch. A compost of three parts fibry loam, one part horse-manure, half a part of peat, and sufficient sharp silver sand to keep the whole porous. Abundance of water is required both at the root and overhead when in free growth. Copious supplies of liquid-manure is an advantage after the pots in which the plants are to flower are full of roots. A cold pit or frame provides the most suitable site for the growth either the first of June, shading the glass lightly during the hottest part of the day. When the flower-buds commence to unfold syringing should cease. The following half-a-dozen are good varieties. For convenience I append the colour of each: Lady of Lorne (blush-pink, large and fine), Mme. Sanzer (light-rose, shaded lilac, fringed and free), Med. Rath Dr. Koch (bright-carmine, lilac and white blotches), Bastian Lepage (deep-magenta, netted darker), Charlotte Boch (dark-purple), Kate Tidy (very fine white variety).—S. P.

—These are rapid growing plants, and small ones now in 4-inch flower-pots ought to grow into exhibition specimens by August. They should be potted out in good soil as soon as they need repotting. It is a grave error to let Petunias get what gardeners call "pot-bound"—that is, the roots matted round and round inside the flower-pot; this gives any plant a serious check, and such specimens would not be likely to win prizes at exhibitions. Any good florist could supply named Petunias, and it is generally best to leave the selection of such things to them. A few really good double ones are: Arlequin, Banquise, Feu Follet, Le Maza, Le Blason, Lutin, La Bourdonnais, Madame Witt, Olyesee, Panama, Pyrrha, and Saint Sasse. The plants are cheap enough, about 6s. to 9s. per dozen.—J. D. E.

—I would advise your potting your plants on into 6 inch pots before they grow any more. Petunias have a downy and very sticky surface to their foliage, and it is impossible to remove any dirt once it becomes attached to them. Great care should, therefore, be used when repotting. Use a compost of half loam, a fourth leaf-mould, and the remainder made up of well-decayed manure and sand. A little coal-soot placed in the bottom of the pot, just above the drainage, helps them very much and adds a healthy colour to their foliage. The foliage should not be allowed to get wet, but an occasional sprinkling overhead early in the morning of a bright day will be found beneficial.—P. U.

3881.—**Cape "Geraniums."**—These are very pretty, and quite unique. I find a mixture of leaf-soil and loam, with a dash of sand, forms a good compost. They are peculiar in being bulbous, having bulbs somewhat similar to the individual bulbs of a Dahlia. They also bear stout thorns, much after Rose-prickles. If your house is in a warm position, and you keep the plants in the warmest part, I do not see why they should not survive an ordinary winter, although your house is unheated.—P. U.

—To give a detailed article on the culture of Cape "Geraniums" would be a very large order. There are so many of them, and they vary so much in character. Some of the Cape Pelargoniums require a warm-house, and the remainder are greenhouse plants; but some will live where exposed to frost. Cuttings will root

and grow freely now; but before frost comes they must be moved where they will be safe from frost.—E. H.

—These, which are seedlings or hybrids from *P. echinatum*, are, like most old-fashioned plants, by no means difficult to grow, and they are comparatively hardy also. Though possessing good constitutions, they do not make such strong growth as many of the Zoules and other large-flowering kinds, so that they should be kept in proportionately small pots, with good drainage and sandy soil. A mixture of good light loam, with a third of leaf-mould, a little peat or Cocoa-nut-fibre, and plenty of sand will grow them well. When the pots are full of roots weak liquid-manure may be given once a week. Ventilate freely, and keep them in a light position in a cool house. Whether or not they will survive the winter in an unheated house depends upon several conditions—e.g., the locality, the aspect and construction of the house, the nature of the soil, and the severity or mildness of the season. As a rule, in fairly warm or sheltered places they will be all right if kept dry and covered up well in frosty weather. They may be propagated by means of either shoot-outtings or cuttings of the thick roots inserted in very sandy soil in the spring.—B. C. R.

—The outtings will strike very easily in pots of light soil, well drained, and placed near the glass. You must pot them off separately when rooted, and use a light soil, and water them very carefully; also look out for greenfly, which may be quickly got rid of by gentle fumigation. During the winter a greenhouse will suffice. The Cape "Geraniums" (they are really Pelargoniums) do not require much warmth, but a cool, not too moist temperature. It is very seldom one sees a good collection nowadays, but at one time they were more popular. Sometimes one sees them used in the summer bedding, but although useful, quaint, and pleasing, thus grown, the leaves flag when cut quickly, and this is not the case with pot plants. The reason is that the plants out-of-doors make rapid growth, less robust, and wiry. There is much beauty in a small selection of this type of Pelargonium, as the leaves of most of them are very pleasantly scented, and there is much diversity of form, some plain, others charmingly cut, crisped, and ornamental, useful for choice bouquets and posies. The flowers are as a rule bright in colour, particularly those of the variety Rollison's Unique, which is of loose habit, and is often seen affixed to a trellis, the shoots tied to it so as to cover the whole space. A great quantity of bloom will be produced, which will last over a long season, in the winter also, and will be valuable for decorations. If required in bloom in the winter, more warmth will be necessary than that of an ordinary greenhouse. A plant may be also grown in a pot in the ordinary way, and sticks put to the shoots as they progress. A considerable quantity of flowers will be secured, or it may be trained up a pillar, whilst for hanging-baskets it may be also used, and a few good examples in the conservatory are very effective. In a selection of these plants Unique should be certainly included, and others that may be recommended are the Oak-leaved kind (*P. querifolium*) the Nutmeg-scented or Lady Mary, as it is also called, the Lemon-scented, or crispum denticulatum, Fair Helen, Pretty Polly, Lady Plymouth, which has variegated leafage, Prince of Orange, Lady Scarborough, and tomentosum. All these are worth growing, and in time you will be able to add others, but these are the finer.—C. T.

—All the South African Pelargoniums require greenhouse treatment, but they can put up with a very low temperature occasionally, although continued frosts would kill them. Most of them would not suffer with the temperature falling to the freezing-point in the house. They might do in an unheated house, if they could be removed to a room in the dwelling-house when very severe frosts set in. Some of the species are evergreen and should not be dried up in the winter, others are tuberous rooted, and are kept without water all the winter; these could be wintered in any room from which frost is excluded. Anyone anxious to grow plants will scheme some method to preserve them through the winter, even if they have to grow them in an unheated house.—J. D. E.

3890.—**Scented Pelargoniums.**—There is a great variety of these. Which do you mean by the "common" one? *P. capitatum* has rose-scented foliage, but I have never seen or heard of *P. odoratifolium*.—B. C. R.

—There are so many fancy names given to the Cape Pelargoniums that it is difficult to answer your question; but the rose-scented kind may be *P. odoratifolium*, a very old species, having been introduced from the Cape of Good Hope in the year 1724. The common scented-leaved Pelargonium is the Oak-leaved, under which name it is known in gardens and nurseries, without using the botanical title. You may sow the seed of Pelargoniums in pots filled with light soil, and well drained. When the seedlings appear and are sufficiently large, pot them off, and keep them through the winter in a warm temperature, say between 50 degs. and 60 degs. In the case of your not being able to provide them with this temperature, the better way is to sow early in the year, giving a good heat, and when large enough pot them on; thumbs first, then sixty size, and so on. It is not difficult to raise plants from seed, but by outtings is the best way.—C. T.

3892.—**Treatment of Smilaxes.**—I imagine you allude to *Smilax myrsiphyllum*, as this is quite a popular plant, and fortunately of easy culture. You had better put your seedling plants into 3-inch pots; with regard to soil it is not very particular; my plants are growing in fairly light loam principally. You are no doubt aware that the sprays of growth of this plant are used for associating with cut-flowers as well as for personal adornment. When it is intended for use in this way the growth should be allowed to support itself in a vertical direction. It readily clings to small wire or twine when so fixed that the shoots can reach the supports as soon as they start from the crown; a temperature of about 50 degs. suits it admirably during the winter. It will endure more cold, but in a low temperature it loses that pleasing green colour that makes it so valuable. Too much sun will also take the green colour out of the small leaves in the summer. The cooler the plant can be grown from May to September the longer the sprays will last in good condition when they are out. The flowers are insignificant, being very small and white in colour: the seeds are enclosed in a round fleshy ball, the latter being bright-red when the seed is ripe.—J. C. C.

—You should pot on the plants as they grow, and they will succeed in the conservatory, as they are hardy, although they dislike keen winds and severe cold. Pot them on, therefore, in ordinary garden soil, and when of sufficient size plant them out. And such kinds as *S. aspera*, *S. tannoides*, *S. rotundifolia*, and others are useful for rearing over tree-stumps or rocks. They are evergreen, and are a change from the various climbers repeated so often in gardens. Keen, cutting winds they dislike. *S. maurandina* has green and white leafage—a pleasing form.—C. T.

3903.—**Building a conservatory.**—If there is to be any considerable length of piping in the conservatory, I fear the apparatus would not act particularly well, for this reason: In cold weather after the water had traversed, say, 100 feet of piping it would be getting comparatively cold. Now, the natural tendency of cold water is to fall, while this would have to rise, or rather be forced, up to the higher level of the bath-room, and the circulation would consequently be more or less sluggish. Probably a better plan, in my opinion, would be to place a T-piece in the main flow to bath-room, with two cocks or valves, the branch leading into pipes in the conservatory fixed in the usual way, with return into boiler. In this way the current of hot water could be turned into bath-room or conservatory as desired; but there must be an air-pipe at the highest point in the pipes, as high as the bath-room tank.—B. C. R.

—If you can command a sufficient force in the boiler that heats the water for the bath-room, I do not see any difficulty in heating the conservatory; but not from a single pipe passing through it, as you seem to suppose. You will require a regular service of pipes, according to the area to be heated, and a separate feed cistern, so as to be able to shut off the water from the bath-room in frosty weather. You do not say so much, but it seems to me that you intend to heat the water by the kitchen boiler.

If that is so, it would be a complicated matter to have more piping than is required for the bathroom.—J. C. C.

3899.—Arrangement of a green-house.—There can be no possible objection to doing as you propose—viz., utilizing the new bonco as a cold or unheated one. Such a structure is useful for many purposes, and at all seasons, and much better than a heated house for wintering choice Carnations, Anrioles, &c. For a structure of this width and description as good a plan as any is to have a solid raised bed, about 4 feet wide and 2½ feet in height, along the front; then a 2½-foot or 3 feet pathway, and another raised etaging or bed rather higher than the other—say, 3 feet at the back—to accommodate large plants. It is as well to have such a house fitted with a thick blind on a roller to run over the roof, for use in frosty weather, and also some pieces to be hung round the sides when necessary.—B. C. R.

— If it was my case I should make the three-quarter span the stove, as this form is much warmer in winter than a whole span, but of course a good deal depends on the position of the boiler, as the warmest house should always be nearest the heating apparatus. The width does not give you much choice in the internal arrangement; a front bench 2 feet wide, and the walk 2 feet 6 inches in width, only leaves 5 feet unoccupied. This latter space would be best filled with a stage, with three or four tiers on which to stand the plants.—J. C. C.

3896.—Young Myrtles.—If the plants make good growth during the summer, and this is well ripened in the autumn by exposing them to the open air and sun, they ought to flower profusely, and when so treated I have never known them fail to do so. This is, in fact, the great secret of securing an abundant bloom. The plants should be lightly pruned annually by cutting out some of the weaker shoots, and then if they get a moderate shift, using good loamy soil, they ought to be covered with blossoms next summer. Do you make the soil firm enough? Or possibly what you use is too rich. They should have plenty of air and a light position at all times when kept under glass.—B. C. R.

— This Myrtles will flower when they get larger and older.—E. H.

— These do not flower until nicely established, and not then freely if allowed too much roofing space. A pot 6 inches in diameter is large enough for a four-year-old plant. Stand the pot out-of-doors in a sunny position to thoroughly mature the growth; but do not neglect to supply the roots liberally with water.—S. P.

Phyllocactuses.—There seems quite a reaction in favour of Cactuses, and those who intend taking up their culture cannot do better than try a few of the Phyllocactuses, which bear splendid flowers of brilliant colours, although, unfortunately, they are not long lasting. But all Cactus flowers—at least, the larger number—are ephemeral, this being atoned for by a good succession, as just as one fades another is expanding. One gets amongst the Phyllocactuses a very beautiful series of coloring—crimson, white, astiny-purple, and allied shades, sometimes shot with a pelocid tint peculiarly beautiful. When the plants are of large size, they bloom profusely. Moreover, they are very easy to grow. The less they are interfered with the better. During the growing season, which commences in spring, and lasts until the end of the summer, the soil must be kept moderately moist, and syringes them occasionally, giving abundance of air, sunshine, and a temperature at night of 65 degs. In the winter an ordinary greenhouse will suffice for them, as when at rest more air is necessary, the soil being kept dry. The flowers appear through the summer. For soil use good loam, mixed with a fair proportion of well-decayed manure, and such material as brick-rubbish, which they like well. A very beautiful variety is called J. T. Pocock, named after a famous amateur grower of Cactuses; the flowers large, about 9 inches across, and of rich colour—crimson, shot with purplish-violet. Delicate (rose), splendens, C. M. Harvey, grandis, which produces its fragrant cream-coloured flowers in the evening, and arenotata are a few of the best. The Phyllocactuses are very cheap, and not long ago a good plant could have been got for a few pence. I do not suppose they are not expensive now.—C. T.

Begonia Gloire de Sceaux.—This is a new winter-flowering Begonia, and is one of the finest things of its class that has been acquired of recent years. It was raised by the well-known French nurserymen, Messrs. Thibaut & Keteleer, Sceaux, near Paris, and is very distinct. The habit of the plant is quite pyramidal, and the leaves effective in colour, green, with a tinge of bronzy hue, and in fine contrast to the flowers, which are large, and a very decided pink colour, in rich contrast to the foliage. If there is a warm house at command with a higher temperature than that of an ordinary greenhouse, this Begonia will thrive well, and in the winter months prove a feature of much interest. It is really a first-class plant, not difficult to grow, and very rich in colour. It is a pity that the winter-flowering Begonias are not more thought of, but they are neglected. There are many beautiful varieties, and a few very easily cultivated. A good plant is B. Corrieri, the flowers white; and nitida and nitida alba are free both in growth and bloom. President Bourneillo, which has bronze-crimson leaves and rich pink flowers, is a kind worthy of mention.—T.

THE KITCHEN GARDEN.

"Exonian" Pea.—This is, as far as I have seen, the best early Pea, and it is a very good cropper. It would suit those who have not too much space to spare for vegetable growing, being compact and about 3 feet in height, whilst it is of first-rate quality, a point of chief importance when considering the usefulness of vegetables. It belongs to the wrinkled Marrow class, and is in every way a fine garden Pea, coming in before other varieties.—T.

3888.—Asparagus culture.—Perhaps too much manure and salt are given annually to the beds, or the roots are too deep, or the subsoil may be in an ungenial state. From the meagre details given it is difficult to say what is the exact cause; the roots may be old and exhausted, or they may be too young. To grow good Asparagus the land should be deeply trenched in the autumn, adding a good dressing of partly decayed manure, placing it between the first and second spit of soil, if harrowed deeper it is useless for the roots, as they would not find it. Good Asparagus can be grown in four years from seed sown in April; it is usual, however, to plant two-year-old roots, which is quicker than waiting for the seedlings as a few heads may be cut the year after planting, it is a mistake to crowd the plants, it is also wrong to plant them deep; a couple of inches of soil is ample over the crowns, finishing off with 2 inches of decomposed hot-bed manure, rotted loam, or vegetable refuse to prevent the soil becoming too dry in the event of it being a hot and dry summer. For convenience in cutting, Asparagus is generally planted in beds of three rows in each, but it is not absolutely necessary that it should be thus grown. It will succeed as well in rows like any other crop, without the trouble of making up beds. Presuming, however, that one bed is only required, the soil having been trenched and manured in the autumn, if the soil is in a fairly dry state the second week in April, a bed 3 feet 6 inches wide should be marked out; with a spade open out a flat trench down the middle, 2 inches deep, placing the soil on both sides of the trench. Place the roots in the trench, 15 inches apart, spreading the roots carefully out to their full length, that their direct progress will not be interrupted. If the soil is light it may be retarded, covering the roots at once, but if heavy and retentive it is a good plan to cover the roots an inch or so thick with soil lighter in character—old potting-soil, wood-ashes, or road-grit will answer admirably—the object being to give the plants an early start. By no means allow the roots to become dry by exposure to the air. The outside rows should be planted in the same manner, 15 inches from the centre row. Many persons not only cover the beds in the autumn with manure, but they dig the soil out of the alleys between the beds, laying it over the manure. This is a mistake, as it not only renders the beds too wet during the winter when the soil is heavy, but the roots which run into the alleys are annually cut off. When the tops have decayed at the end of October they should be cut off close to the soil, all weeds cleared off, a coating of partly

decayed manure, 3 inches thick, spread over the surface. Early in April following the roughest parts of this manure should be raked off, so as not to interfere with the heads peaking through. A slight dressing of common salt is beneficial at the same time if the soil is light, but where it is heavy it is not wise to employ much salt. It has a tendency to make the soil wet. After cutting is finished in June give the beds a thorough soaking, if possible, of liquid manure, to stimulate growth for next year's supply.—S. P.

— There must be a cause for the Asparagus growing so thin and weak. Are the beds cut from too much where the plants are? Manuring is not always sufficient to regulate the cutting, so that the plants may begin growth earlier, or, in other words, discontinue cutting much earlier. It will be better to take only a dish or two from a weak bed for a year or two till the plants have got strong. Asparagus is not difficult to grow, but many of the old beds were planted much too thick in the first instance, and, in some cases, the seeds were permitted to ripen and drop about the bed and grow, and the plants permitted to remain. In overcrowded beds the grass must be poor and thin.—E. H.

3400.—Mushrooms.—Where all the details have been carried out with so much care it is difficult to understand the cause of your failure. On the other hand, Mushroom culture is such an uncertain undertaking, and a failure brought about by such trifling circumstances, that one does not feel surprise in such a disappointing case as yours, because, if the surface of the bed was allowed to get dry, or the heat suddenly decline, that would be sufficient to account for your failure, or it may be that the spawn was bad to start with; this, however, is not likely; want of sufficient heat and a dry surface I believe to be the cause.—J. C. C.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clear and concisely written on one side of the paper only, and addressed to the Editors of GARDENING, 37, Southampton-street, Covent garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING is sent to great numbers in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question will often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

3908.—Roses in hanging-baskets.—Are Roses ever grown in hanging-baskets? If so, what kind of Rose is best adapted to the purpose?—C. S. C.

3909.—Treatment of a Lilium Harrini.—What should be the future treatment of a Lilium Harrini which has just flowered well in a pot?—E. M.

3910.—Fruit-trees against a north wall, &c.—What fruit-trees may be planted against a north wall, and what Roses and other Climbers against an east wall?—S. D.

3911.—Rhubarb from seed.—I have some Rhubarb raised from seed last year. What is the best treatment for it, and how long will it be before it is large enough to pull?—E. K.

3912.—Plants for a shaded wall.—What would grow well on a brick wall 2 feet high, shaded by a large Horse Chestnut? Would any kind of Rose flourish there? Mine is an excellent soil for Roses.—CAROLINE A. OATES.

3913.—Growing Tobacco.—Where can I obtain information respecting the growing of Tobacco in England, and why it should not be grown with profit in this country, as I believe it once was?—B. M. STANLEY.

3914.—Tar paths.—Will someone kindly give the necessary instructions how to make tar paths for a garden? Those I have seen are either soft and give in warm weather, or they crumble and appear to be rotten.—W.

3915.—Plants for a small pond.—I shall be glad to know the names of some aquatic and water-plants for a small pond, and hints as to planting? Also, what plants should grow round the sides and on the bank of the pond?—B.

3916.—Treatment of Croumbers.—I have small Croumbers and I have obtained three Croumber-plants. Not knowing how to treat them in stopping and setting of flowers, I ask if anyone would kindly instruct me?—TELEGRAPH.

3917.—Lilies and Irises for market.—Will anyone kindly tell me whether the growing of Lilies and Irises in quantity for the London markets is likely to prove profitable in this climate (Thames Valley), given suitable soil?—AUSTRIAN.

3918.—Painting hot-water pipes.—Will someone kindly say which is the best mixture for painting hot-water pipes to be a nicelblack? I once saw a receipt in *GARDENING*, but cannot now find it. Pipes are all new in three varieties.—EQUILIBRIUM.

3919.—Classes of Roses.—Would someone kindly let me know how I can distinguish between the different classes of Roses—Rosa, Hybrid Perpetual, Tea, Noisette, Fairy Bourbon, Damask, Provence, &c.—and state their different treatment principally?—JAMES SAKON.

3920.—Treatment of Peaches.—Succession shoots on my Peach-trees are sending out other young shoots from axils of the leaves where flower-buds should form next year. What am I to do? Also, should I stop the leading shoots, which are growing strong?—ANNOTS.

3921.—A pale blue Clematis.—Which would be the best white or pale-blue double or semi-double Clematis to grow in a pot to flower in winter in a greenhouse, and produce flowers that would stand well when out? Would a double Broombe answer for this purpose also?—ZONIA.

3922.—Beetroot and Oslary.—I should be much obliged if anyone would give me some information on the sowing of Beetroot and Oslary seeds. Ought they to be sown now and in what soil; also which are the best sorts for sowing in the open air, as I have no means of forcing them?—H. M. P.

3923.—Bedding-plants.—I have a nice lot of Chrysanthemum *Chrysanthemum* in small pots, and should be very glad if someone would tell me if I can use them in any way for bedding with *Alternanthera* or *Mesembryanthemum* cordifolium var., or what is the best thing to do with them?—E. ROWLAND.

3924.—Fowl droppings.—I should be glad to know whether bird droppings can be used to make liquid-manure for such things as *Violets* in pots, *Anemones*, and the other ordinary plants in a herbaceous border? If so, what proportion of water should be put to the droppings, and how long it should stand before use?—F. G.

3925.—Gardening for profit.—I wish to start gardening with a view to profit in Flintshire. Would anyone give me advice as to the best way to begin, what crops to grow, and the probable outlay per acre? The soil is clayey. Apparatus does very well, and comes in early in the garden, about 6 miles from the sea.—PERRIN.

3926.—Management of a hedge.—I should be glad of advice as to how to strengthen and thicken a hedge some 300 yards in length? The hedge is principally Hawthorn, some 5 to 6 feet high, but has been badly made with side bushes here and there, and is straggly and very weak in places, worst near the ground.—ACTUS ALIENUS.

3927.—Pigson's manure for Chrysanthemums.—Would "E. M." or some other experienced man be kind enough to say whether the above in a dry state is good for mixing in the compost for the final potting of Chrysanthemums? If so, in what quantity might it be safely used? Any information will be thankfully received.—G. N.

3928.—Treatment of a Magnolia.—I have a *Magnolia* some 10 years old, which has always looked most vigorous, and has bloomed freely; it is getting thin in foliage, the buds are not lustrous as usual, and there is a good deal of dead wood about the end of the branches. Should I manure it, or what better treatment can be suggested?—GASTALINDA.

3929.—Pinks losing colour.—Will someone kindly tell me the reason of my hrow-edged *Pinks* losing their border this season? They were heavily flowered the last three years, and now they have only the dark centres. They have had manure, water, and the plants are healthy. Can it be that the white *Pinks* in the same row have got mixed with the dark sort, and so deteriorated them?—M. S.

3930.—Seedling Grape-Vines.—I have three seedling Grape-Vines. They came up in a garden in the spring of 1887. They were neglected for two years, and then came to me. I planted them in an inside border of an unheated greenhouse facing south. They are very luxuriant, but have never had a bloom. The wood was ripened last year well. They are not out-of-door Grapes, and two seem alike. The other comes into leaf later. Will someone tell the reason of their not fruiting?—G. L. HURLES.

3931.—Insect pest.—During last summer I was much troubled with multitudes of small dark-brown spots made by some insect on my window-curtains, cushions, and almost every article in my rooms. I was unable to discover whether they were made by moths or flies, as I did not see an unusually large quantity of either. The same thing has already commenced this season, and I shall be glad if someone will tell me the cause and the best remedy? My house is in the open country, and the windows are open a great deal.—L. M. N.

3932.—A small flower garden.—I should be glad to have suggestions for the arrangement of a small flower garden, the parties of which are 12 feet wide, and 12 feet long, runs in a parallelogram north and south, length 30 yards, width 14 yards, surrounded on east side by very high Portugal laurel fence, on west by a low Yew-hedge, on south by a small planting of trees and shrubs, on north by a few shrubs and trees, 500 feet above the sea, and within 5 miles of it. I wish to give interest and variety to the ground, and to have herbaceous things principally.—R. T. JOHNSON.

3933.—*Centaurea candidissima*.—Will someone kindly give me advice as to what I can do with *Centaurea candidissima* in the way of bedding them out? In what way can I use them? Would they do for an edging to a bed of *Scabellia "Geranium"*, or would they do to fill the centre of some small round beds, the outside of the bed to be filled with *Alternanthera* *alternans* and *magnifica*, or could they be used in any way with *Labellia* or *Golden Feather* or *Mesembryanthemum cordifolium variegatum*? I should be glad to know, as I have a lot of nice seedling plants in small pots and want to use them, and don't know the best way.—E. ROWLAND.

3934.—A small town garden.—Some time ago I engaged a gardener to renovate my small town garden. For the purpose of making two flower-beds he removed a quantity of turf and afterwards buried it beneath the soil there, and in the borders. I find now that the Grass is beginning to crop up alarmingly, and removing it with the hand brings up the obnoxious turf on its surface. What can I do to eradicate the pest short of removing the said turf altogether? Will anyone also kindly inform me how to prepare a bed of soil for Roses and what Roses, standard and climbing, will suit a south-easterly aspect in this northern climate?—EOMUSCUS.

3935.—Unhealthy Cucumbers.—I should be very glad if anyone will tell me what is wrong with my Cucumbers? About fourteen days ago I noticed young fruits drying up, so thinking they were damping off gave less water and more ventilation; then more seemed to go and plants looked worse, leaves drying up; I gave more water. Last week I noticed some very small light-brown insect on end and under leaves; I mingled with Tobacco-ashes, and in some were there still. For improvement next week shall clear all out, coals as well, try fresh lot. Would like to know what it is and what is the cause? It is my first time of growing Cucumbers. They are *Looke's Perfection* that I have in. They are grown in a span-roofed greenhouse facing south; district, Stockport, Cheshire.—R. G.

3936.—A lean-to Peach-house.—I have one of these unheated, aspect south-east, some 60 feet long by 12 feet wide at the base, contains Peach-trees trained to a wire trellis against the wall at the back, and a row of standards on the border near the glass. All these are in a most unhealthy condition, worse on one end than the other. Those against the wall have their branches twisted and distorted, and except towards the ends are bare of leaves, like stags' horns. The foliage, where it does occur, is crinkled and be-rotted, except here and there some long twig shows a more normal development; but then the leaves are light-coloured and sabby, and mottled with yellow. A few fruits have set in places on these trees. The standards near the glass are dead and dying, with distorted branches, as the others. Some young trees were purchased and planted last year. Of these four or five are all dead, never having made any growth at all. Others are just alive, and only one at the better end of the house shows any vigour; but here also the leaves are mottled with yellow patches. The trees are clean of mealy-bug or anything else, but that is the cause of their state, and what would be best to place the trees in a healthy condition?—FRANCIS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3937.—*Epidendrum vitellinum majus* (J. Kerriell).—This is a plant that luxuriates in a cool, moist temperature and in the shade, and, I imagine, it is because your neighbour's plants have been subjected to this, the right treatment, that they look so well, and are flowering now so well, and your own plants are looking so badly and showing no disposition to flower simply from the fact of not having been similarly treated. See previous allusion to this species, where you will always find it recommended as a cool plant.—M. B.

3938.—Plants for a stove-house (W. Ball).—This gentleman wants to know what plants he can use for such a structure 60 feet in length, 15 feet in width, and 10 feet in height? Well, there are many things you can have in such a structure. For the principal things I should have, say, a dozen *Tulips* of good distinct character, and the same number of good coloured *Orchids* of distinct character, some few *Anturiums* and *Aloes*, a few *Dracenas* for shady spots, and a few *Nepenthes* or *Piper*-plants. These would make you a good permanent backbone for the general ornamentation of the house. The intervening spaces you can fill up with other ornamental-leaved plants and flowering plants as fancy dictates; but take my advice, and go in for some of the more ornamental kinds of the *Bromeliad* plants.—J. J.

3939.—*Caladium leaves* (M. Kelly).—These came to hand in very good order, but I cannot name them. You should send them to some grower of these plants. I should say that J. Laing and Sons of Forest-hill are probably the largest and best growers of these plants you could find, but be sure you get the ones you want, which, by the way, was not the case with those sent me.—J. J.

3940.—*Olivia miniata* (John Holt).—I cannot undertake to name this variety, but if you have a plant with four good heads upon it, it is in very good order, and worthy of a place in a collection at any exhibition, staging as a greenhouse plant in a collection of mixed stove and greenhouse plants. Your flowers remind me of the form called *Marie Ramirez*, but I could not say for certain. You will be quite correct if you call it by its typical name, and that I would do.—J. J.

3941.—*Maxillaria lutea alba* (J. McDougall).—This is the name of the flower sent and a very fine form of the plant you have. The plant has been growing very robust, and the number of flowers your friend has upon the plant should convince you the treatment given to it is quite correct, and you cannot do wrong if you follow it implicitly.—M. B.

3942.—*Cypripedium spectabile* (Henry Bennett).—Yes, this is a very good coloured flower of the species named above. You may have many of these beautiful *Moccasin*-flowers and never have so good a one. I have grown this plant in considerable numbers, and have seldom got a better one, but many inferior to it in the rich bright colour of its pouch.—M. B.

Catalogues received.—*Strawberry plants*. Mr. T. Laxton, seed and novelty grower, Bedford.—*New and Rare Plants, Orchids, &c.* Mr. William Bull, 536, Kings-road, Chelsea, London, S. W.

Books, pamphlets, &c., received.—"Practical Fruit-growing," by Mr. J. J. Neel. Messrs. George Bell and Sons, York-street, Covent Garden, London.—"Johnson's Gardener's Dictionary" (Part IV). Messrs. George Bell and Sons, York-street, Covent Garden, London.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

J. H.—Mildew very bad. Dress over with sulphur or one of the compositions for destroying mildew as advertised in *GARDENING*.—Dot.—We do not know of any Encolpium that will stand the degree of cold named. Is it some other tree you mean?—G. Cummins.—You should advertise.—Mrs. Molloy.—Apply to Mr. A. G. Budler, The Lilies, 124, Beckenham-road, Beckenham, Kent.—S. H.—We think it would be best to try the *Prigolias*. What is it you wish to know especially about their treatment?—C. A. W. Cottrill, *Smilbury*.—The Grapes are "acidified" from want of early ventilation in the morning and a consequent damp atmosphere.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of *GARDENING ILLUSTRATED*, 37, Southampton-street, Strand, London, W. C.

Name of plants.—*Scot's-gap*.—Ribes aurum. Constant Reader.—We cannot name garden varieties of Plinks.—James F. Smith.—Yes, *Cottley's Mossin*.—Roma.—*Orangius Pyracontha*.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of *GARDENING ILLUSTRATED*, 37, Southampton-street, Strand, London, W. C.

Names of fruit.—C. E.—We cannot attempt to name Apples at this late season of the year.

BIRDS.

3943.—An ailing Canary.—I have a Canary which peels the skin from off its feet and then eats it. Would you kindly tell me the reason, also cure? It is a last year's bird, sings beautifully and seems in excellent health. Its cage is thoroughly cleaned two or three times weekly, and the bottom lined with bird sand. Its food consists chiefly of Canary-seed with an addition of Rape, Millet, Ings, and a very little Hemp.—READER OF *GARDENING*.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in *GARDENING ILLUSTRATED*.

"Gardening Illustrated" Monthly Parts.

"The Gardener" Monthly Parts.—This journal is published in nearly bound Monthly Parts. In this form the best prices are offered, and it is most suitable for reference previous to the issue of the half-yearly volume. Price, 1s. 6d.; post free, 1s. 7d. Complete sets of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Farm and Home" Monthly Parts.—This journal is published in nearly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volume. Price 6d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. *Fourth and Popular Edition*, 1s.; post free, 1s. 2d. London: 37, Southampton-street, Strand, W. C.

OUTDOOR KINO TOMATO.—The best kind growing in the open air, whilst it may also with advantage be grown under glass. *Shilling plants*, 1s. 6d. dozen, free. Post during June.—O. SHILLING, Nurseryman, Winchfield, Hants.

INCORPARABLE RIDGE CUCUMBER.—1 fruit 18 inches by 22 inches, best for outdoor growing, plant now, 6 for 1s. 6d. New Japanese Cucumbers, 3 for 1s. 6d., carefully packed, carriage paid.—O. SHILLING, Nurseryman, Winchfield, Hants.

TELEGRAPH CUCUMBER.—Best for 1 greenhouse or frame, strong plants, 3 for 1s. 3d., carriage paid. Vegetable Marrow plants, 3 for 1s. 3d., carefully packed.—O. SHILLING, Nurseryman, Winchfield, Hants.

TWOPENCE per packet.—Choice Seeds.—1 Sow now. *Prinella*, *Chiranthus*, *Calceolarias*, *Oxyclematis*, *Pansy*, *Cornish Primrose*, *Wallflower*, *Ukiahalla*, *Veronica*, *Cardinal*, *Crocus*, *Flax*, *Canna*, *Geum*, *Geranium*, *Heliotrop*, *Palms*, *Fias*, &c. 1s. worth post free. *Himrodia testiculalis*.—O. SHILLING, Seedsmen, Winchfield, Hants.

OS. 6d. COLLECTION OF OHIO GREEN.—4 HOUSE PLANTS is a marvel of cheapness, contains 24 good plants of sorts for potting up to make greenhouse gay all summer. Order at once, 3s. 6d., carriage paid.—O. SHILLING, Nurseryman, Winchfield, Hants.

QUOXINIA SEEDLINGS.—Bloom this year. *G* Best prize spotted and named strain, 12, 3s.; 1s. 9d.—THOMSON, Chesham-place, Wakefield.

FUNKIA (Plantain Lily), 2 grandiflora, 2 aurea variegata, large strong plants, 1s. 6d., free.—W.M. MUNRO, Ormskirk, Lancashire.

GERANIUMS.—Autumn struck *Scarlet Veil*—1s. 3d. dozen, 1s. 100, 6s. 1,000. *Lady She-Maid* and *Irish-lark*, 1s. 3d. dozen, 10s. 100. *Calceolarias*, dark 1s. dozen, 6s. 100, post free.—A. ROBE, Crowsborough, Sussex.

PRIMULA SINENSIS of the finest strain and various colours. Strong sturdy plants for potting at once. *Best*—1s. 6d. per dozen, 1s. 6d., post free.—E. W. DANON, Bookish End, Brentford, Essex.

Gloire de Dijon is another good kind, the plant making strong growth and bearing freely its well-known fragrant flowers, yet not so freely as in the country, when tumbling over a cottage porch. But within the metropolitan radius excellent results may be obtained. A very fine town Rose of the Hybrid Perpetual class is Captain Christy, the flowers of which are of a soft flesh-colour, deepening in the centre, full, large, and handsome. The foliage is good, and in every way this is a fine town Rose. Chestnut Hybrid I noticed recently blooming remarkably well in a town garden and the crimson flowers were produced very freely. This is a good town Rose, and one of the best climbers. I must confess that I do not care greatly for its colour, which quickly goes dead, but it is a free and in every way useful kind. A very fine Rose is Mrs. John Laing. It is vigorous, and succeeds well everywhere, certainly the best Hybrid Perpetual raised of recent years. The growth is strong, and the flowers of full, handsome shape, the colour rich-pink. Tea-scented varieties are very poor town kinds, but Mme. Lambard will give fairly good results. The plant is very free, and the flowers of distinct colour, salmon-pink, but it varies somewhat. These six kinds I have seen doing well near London, and as many who have gardens in the suburbs often ask for a few good kinds to grow, these were made note of.—V. C.

Japanese Roses and their Hybrids.—The Japanese Rose (*Rosa rugosa*) and its hybrids are beautiful in the garden, the growth spreading into a dense bush, conspicuous for handsome glossy-green foliage, and large single rose-purple flowers. These are produced until the autumn, when one gets the advantage of large crimson hips or fruits that are showy and handsome. Of the variously-coloured varieties none is more charming than alba, which, as the name suggests, has pure-white flowers, quite without colour, and like those of the parent, very sweet-scented. I think the White Japanese, or Kaimama Rose, is one of the most lovely flowers of the garden, and when cut a bunch of them is extremely pleasing in a bowl or glass. The *Rugosa* Roses are vigorous, hardy, free, and what is of great importance, rich in fragrance. A distinct and beautiful hybrid is called Mme. Georges Bruant, the flowers paper-white, and borne freely in clusters. It is a distinct and valuable garden Rose. Speaking of fragrance, reminds me that a variety named Comte d'Eprenil is one of the most fragrant Rose I know. Its flowers are semi-double, rose-purple in colour, and so fragrant that a few will scent a large room. It is as free and vigorous as the type. This question of fragrance is important, and there is a tendency to praise Roses that are absolutely scentless, a grave error, as scent is one of the most precious virtues of the Rose. No matter what its colour, form, or other qualities, if a variety lacks fragrance it is deprived of its chief charm. Roses such as General Jacqueminot, perhaps the most popular of all Roses, is richly fragrant, and no new kind should be praised unless it possesses this characteristic of the queen of flowers. The *Rugosa* Roses are very sweetly scented, which, together with their hardy, vigorous character, also continuing in bloom throughout the summer, should make them still more popular.—C. T.

3908.—Roses in hanging-baskets.—There is no reason why Roses should not be grown in these, providing a proper selection of varieties has been made. If only an upright growing variety is required, I would choose those of the *Polyantha* section, such as Red Pat, Little Dot, and others. If intended to droop, choose Jaanna Ferron, Max Singer, and other more vigorous varieties. You must, however, be certain that they have plenty of water while in such a drying position as hanging-baskets invariably occupy.—P. U.

3919.—Classes of Roses.—The distinctive features in the different classes of Roses cannot be clearly defined by describing them. If you wish to become acquainted with the different characters of each you will certainly have to educate yourself by observation, and that is not difficult. For instance, if you had a bed of, say, twelve varieties of Hybrid Perpetuals, and another bed of the same number of Teas, you would soon see the difference when they were in growth. The Bourbons are quite distinct from

the Hybrid Perpetuals in the autumn by the freedom with which they then flower.—J. C. C.

—“Irish Saxon” seeks a very difficult question indeed. Even professional growers are very doubtful to which class several Roses belong. As to stating how to distinguish between and treat each separate class, I am afraid it cannot be done on paper in a sufficiently clear enough manner to be of much service. There are many more classes than “Irish Saxon” names, and they can only be recognised from a long and close experience of their separate characteristics; even then, as before noted, there is much doubt in several instances.—P. U.

GARDEN WORK.

Conservatory.

There should be no difficulty in keeping this house gay now, but in the plenitude of flowering-material do not be tempted to overcrowd and spoil the effect by dead leaves and naked stems. Crowded plants must lose all their bottom leaves, and there is a difficulty in watering properly plants which are buddled together to form a bank of bloom, as it is termed. Climbers, to be gracefully effective, may be permitted freedom of growth, but a good deal of thinning must be given to the *Troscandine*, *Passiflora*, flowers, and other rampant growers, or mischief will be done by overcrowding. We want to steer a middle course to avoid the formality which growth tied closely in always presents, and yet not to shut out the air and sunshine. Ventilation is a simple matter now, and consists in giving all the air possible during the day when the weather is calm and fine, and leaving sufficient ventilation at night to keep the air sweet and pure by free circulation. By-and-by, when the nights are warmer, the top ventilator may be left open all night. Plants having pots well filled with healthy roots will use up a good deal of water, and liquid-manure should be given twice a week, or, in some cases, if used weak, it may be given more often. Houses which are not shaded by climbers must have canvas blinds provided for rolling down when the plants appear distressed in hot weather. Calceolarias of a good strain are very showy. Keep them in the coolest part of the house and shade, and they must have plenty of water. In many gardens Malmaison Carnations are special features, and very beautiful they are when well done. A large group enclosed with Maiden-hair Ferns, will have special attention. It is not every grower who succeeds with them. In the matter of soil they are very particular. The loam and peat must be of the very best quality, and when both are equally good they may be used in equal parts, with a fourth part of good leaf-mould added. I have seen them grown in peat and leaf-mould only, but to give the plants staying power, some good loam is required. One of the best growers I know turns his old stock plants out into a pit, where a bed of the right kind of compost has been provided for layering the shoots. Here they make very fine strong plants, and it is quite useless starting with weak layers, as they cannot make strong plants. There are several healthy in blossom now which are very attractive in a cool conservatory. *Exochorda* (yellow) and *E. ventricosa* and its varieties are among the best suitors to grow. *Spiraea* which have done flowering should be planted out in a cool spot, and be well supplied with water. The hardy shrubs which have been forced may now be plunged outside to save labour in watering. Pot off seedling *Primula obconica*. Old plants may be divided and grown on for autumn flowering.

Stove.

Glaxias may be moved out of the stove now, and placed in a small house by themselves, mixed with Maiden-hair and other Ferns, the effect will be charming. A light shade will be necessary during hot, bright days. The beautiful *Streptocarpus* hybrids will associate very well with the Glaxias, and may be raised from seeds very easily, requiring much the same treatment given to the Glaxias. The beautiful winter-flowering *Gesnerias* will now be on the move. A few of the neocoma (*yellow*) and *E. ventricosa* and its varieties are among the best suitors to grow. *Spiraea* which have done flowering should be planted out in a cool spot, and be well supplied with water. The hardy shrubs which have been forced may now be plunged outside to save labour in watering. Pot off seedling *Primula obconica*. Old plants may be divided and grown on for autumn flowering.

Ferns.

Hardy Ferns under glass are very beautiful just now, and are just the class of plants that an amateur might grow with advantage when his conservatory is in an aspect not suitable for flower culture. They will do very well planted out on rockery mounds if the work has been well put together, so that the roots of the plants will have a chance. Good loam and leaf-mould, with some sharp sand, will grow most of the varieties in perfection. If grown in pots, and the pots are plunged in Cocoa-nut fibre in winter, no artificial heat will be required. Tropical Ferns are now grown freely, and, where lightly shaded, are of a beautiful dark-green colour. When exposed to strong light the

In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

colour changes to a light-green, which is not so effective either in cut state or otherwise. Ferns must have abundance of moisture now. Shift on any plants which require more pot-room.

Chrysanthemum.

These should now be placed without delay in the flowering-pots, which should not be less than 9 inches in diameter. After potting stand in lines in an open situation, the stakes to be fastened to a wire soursed, stretched to the upright stakes of the plants. The weather will alter the time of the appearance of the buds; some, in fact, are showing buds now, which will have to be sacrificed. The soil for the last shift must be good and turfy, and be firmly rammed in, space being left at the top for top-dressing later on, as well as for watering. Stimulants will not be required yet, but a little soot and bone-meal may be mixed with soil for potting.

Frames.

will be found useful now for growing on young plants of many kinds, and are, in fact, indispensable for *Cinerarias*, *Cyclamens*, *Primulas*, &c. Frames are also very useful for Cucumbers and Melons at this season, where house accommodation is limited. In cold districts Capsicums are better planted under the shelter of glass.

Mushroom-house.

A good watering with liquid-manure will often resuscitate an old bed when the spore is not altogether exhausted, and a handful of salt to each large pail of water may be usefully given to Mushroom-beds at any time. In making up new beds indoors or outside get the manure fresh from the stable and mix good loam to the extent of one-third, and when the heap gets warm stir up the bed and spore as soon as the temperature is steady at 85 degs. or 90 degs.

Window Gardening.

Window-boxes and vases or tubs filled with plants for standing in corners anywhere about the house should be well supplied with water. This duty is often delegated to some of the boys no special interest in their work being attached to it. Foliage plants and Ferns, too, are well suited to liberal supplies of water when the pots are full of roots. A liquid or dry stimulant may be given if it is desired to keep the plants in small pots.

Outdoor Garden.

The Clematis family are flowering better than usual, showing that the bright sunshine and drought agrees with them. A few notes may be taken of the plants which are resisting drought the best in the herbaceous borders. Among the plants which are doing well without watering are *Delphinium*, *Chrysanthemum maximum*, *Gallardias*, *Persicaria Corniflora* (*Centurens*), *Lupinus*, *Anchusa Italica*, *Geums*, *Potentilla*, *Rocket*, *Day Lilies*, and *German Iris*. I have only named a few things which everybody may grow. *Phloxes* and *Hollyhocks* must have plenty of support or the stems will be poor; a good heavy mulch of manure will be beneficial. Roses are doing fairly well in good deep soil, but on poor hungry land there cannot be fine blossoms; this also is worth making a note of. We may not hear another season like this, but short bursts of dry, hot weather are very trying to any plants in a badly cultivated soil. A dry, hot season often leads to an increase of weeds in the lawn. Daisies and other weeds in hot weather soon rush up to flower and the seeds ripen quickly, and if the machine is taken off the seeds ripen, drop out, and grow in due course. I saw a curious instance of the spread of *Daisies* in a lawn a few days ago. There had been an edging of *Daisies* along the front of a border running along side a lawn; they had flowered freely, the seeds had ripened, and some were scattered along the edge of the lawn. These, in due course, flowered and seeded, and the seedlings deteriorated till they could be recognized as the product of double flowers. Where water is plentiful and can be distributed with a hose, I should certainly water terraces and lawns. Stake and tie hardy plants.

Fruit Garden.

Let me urge all who have the means to water their fruit-trees freely. Oh! for a good supply of water with a hose and plenty of pressure for distribution. This is the only economical way of watering an orchard. Water runners must be set close to the trees if the fruiting plants have to supply them. Unless the beds have been watered liberally the sooner the runners are layered for early forcing the better. Melons, both in frames and houses, must be well nourished; if the roots are permitted to get dry there will be red-spider. At the same time, if the centre of the lights are deluged with water, and there comes a change in the weather, canker may make its appearance. In watering Melons there is no necessity for watering close up to the main stem, as all the best roots are some distance away from the centre. The thinning of Grapes in late June will now be pretty well finished, except in houses where no fire at all is used, and the borders may receive a dressing of some kind of stimulant. I used the patent silicate last year, and shall try it again this. It may be used freely, a couple of pounds to the square yard, but will not be too much, but it should not all be given at once; give half now and the remainder in three weeks or a month's time. Scatter it on the border and water it in. Lateral growth must be kept down before much extension takes place. Go over Peaches on walls for last time, and complete the thinning of both fruit and young wood. There is a good deal of crowding of both fruit and wood in small gardens to the injury of the trees. Give support in the way of mulch and water to Raspberries.

Vegetable Garden.

The kitchen garden is often in a bad condition in dry times, and I am afraid many vegetable gardens are in a bad way through the drought. Hope springs eternal in the human breast, and the kitchen gardener, whose hands are tired for want of manure and the labour to apply it, hopes on that the rain may come and give succour to his Cabbages and Lettuces, and cause the seeds to germinate. The chief lesson to be learnt from the present state of things is to manure more liberally and dig deeper. It is not of much use to plant the large Marrow Pea after the middle of June. Second Earlies and the very early varieties follow on till the first week in July, after which we must trust to second crops of blossoms or older

plants which sometimes throw a good crop. I never remember to have seen early Peas so dwarf as this season. They are the best I ever raised, but the sides of the rows will be very valuable. Tomatoes will not bear much neglect in trimming and stopping young growth. If left long in a crowded condition disease steps in and attacks the foliage. It is doubtful if any useful remedy for the destruction of the Cladiporium has yet been discovered, therefore, it will be better to keep the plants healthy by maintaining a buoyant atmosphere; it need not necessarily be always dry if not stuffy. It is possible to keep Tomato houses fresh, especially in weather like the present, and then the blossoms will fall to rot for want of nourishment. Brussels Sprouts for first crop should be got out early and kept moving by watering and hoeing. Horn Carrots may be sown any time till middle of July to supply young roots. The same may be said of Parsley if there is likely to be any scarcity. I do not remember to have seen kitchen garden crops so unsatisfactory as they are in some gardens this year.

F. HORDAY.

Work in the Town Garden.

The welcome rain we have just had has freshened up every thing wonderfully, and sotted newly-planted bedding plants in the ground nicely. Watering by hand is all very well and often keeps things alive, but they never grow in the way that they do after rain. Bedding out should be finished off at once; even Dahlias, Begonias, Coleuses, and the more tender things may safely go out now. Asters, Phlox Drummondii, and other half-hardy biennials ought also to be planted without delay. Either seed or plants may be had and arranged in separate colours, but for my own part I always think the mixed beds look best. The best Dahlias for town gardens are the ordinary garden varieties; the very large-flowered "show" kinds are for the most part too shy, and so are many of the Gactus Dahlias, especially those which are light and fresh, and are not very hardy. Many of the Pompones are very fine, and so are the single varieties, but, though pretty, these last are very fugitive, and soon drop their petals when out. When out-flowers are in request, Firm King, a fine crimson-scarlet Cactus of decorative kind with rather small flowers, and Guiding Star, a large, pure-white Pomponé, should be grown in numbers, as they are both exceptionally free, pure and rich in colour, and of a nice useful size for decorative purposes. In a temperature a little above that of an ordinary greenhouse Gloxinias are very attractive now, where started moderately early. Seedlings sown early in the year will be getting crowded in the boxes into which they were picked off, and should be transferred singly to small pots with a rather close and moist atmosphere, and shade from sun, they will grow very fast now, and begin flowering in July or August, though it is as well to give them a small 4-inch pot first, if possible. Streptocarpus, too, are flowering freely. I believe there is a great future before these plants. They are as pretty as Gloxinias, though not so large, of a more wiry and hardy nature, and bloom continuously for months together. Those who have no heat may sow seed in the greenhouse now, keeping the pan moist and shaded, and the plants so obtained will flower abundantly next summer. Begonias must be shifted on into larger pots directly the first become fairly full of roots—that is, if large specimens are wanted, for if allowed to get pot-bound they rush into flower directly, and make but little more growth afterwards. Tomatoes must have liquid-manure as soon as they begin to carry a few pounds of fruit, especially if the root-run is limited. E. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from June 10th to June 17th.

Shifted on young seedling plants of Asparagus plumosus a mass from small pots to larger ones. This is one of the plants we are never likely to have too many of. If more plentiful it would become very popular, as it does well in the room. To obtain large sprays for cutting, plant this and A. tenuissimus out in a rather warm house, and train them up under the roof. M. de la Roche which are growing in one of the greenhouses, and which were cut down a month ago, have broken well, and some of the weakest shoots have been rubbed off. The plants are getting hardy generally. I always make it a rule to keep a few young Melon and Cucumber plants in stock in case a plant goes off. Pegged down Verbena, Heliotrope, Agrostis, &c. If this work is left too long the growth gets hard, and then the stems strip off. Progress in the kitchen garden is slow painfully slow, in consequence of the drought, but a good deal is being done with mulch and water, and I have never been so free from weeds. Finished thinning into Grapes—at least, all have been gone over once, but many branches will require looking over again to remove small berries, and take a berry out here and there where crowded. Dressed all the inside borders with the patent silicate manure, and afterwards mulched with horse-droppings which have laid in the sun and got partially dried. All our watering, so far as regards the borders, is done with the hose—it saves so much labour. When I look at the immense amount of work which can be done with a good water supply, and pressure enough for the hose, I cannot understand why in every garden the water supply is so limited and so difficult to apply. If there are no ponds, rivers, or water-courses near, water enough for every purpose may be found by sinking a well, and putting down a pump which might be so constructed as to be worked by the wind, or by a small steam-engine. Of course, this and the building of the elevated tank would cost money, but it would pay in the long run. But we are a conservative people, and stick to old notions, often at a great occasional sacrifice. Is it any wonder that agriculture languishes? Picked the flower-buds of Fuchsia which are required to flower late, out down early-flowering Palæodolium, and put in the cuttings. They will strike anywhere now if kept in the moist. Filled a small frame with cuttings of several varieties of Evergreens and variegated Euonia; will be kept close and shaded; the cuttings were taken from the young shoots. Watered a bed of standard Briars intended for bedding. The drought has checked their growth, and a soaking of water will set the tree. Planted out a lot of choice new King Carrots, sowed a bed of Parsley, and hybrid Cauliflowers. These are

beautiful border plants, and should be in every garden, especially where out-flowers are in demand. Finished gathering the Waterloo and Alexander Peaches; with me these two Peaches are very much alike; I have both growing in one house. There is not much forcing, and I commenced gathering Waterloo end of May, and Alexander came in a few days later. If they would only set as freely as Hale's Early or River's Early York their value would be much greater. Shifted on Zonal "Geraniums" for winter-flowering, sowed a bed of Brompton Stocks. Finished pinning out bedding plants. Sowed Tuniopsis, planted Brussels Sprouts, Vetch's Autumn Cauliflower, and Celery.

TREES AND SHRUBS.

SAND MYRTLE (LEDUM BUXIFOLIUM)

Oh, to be quite correct, *Leptophyllum buxifolium*, is a remarkably variable and very distinct little shrub, useful alike for the bed or the border. It is popularly known as the Sand Myrtle, being a native of the sandy Pine barrens of New Jersey. On account of its dwarf, evergreen, free-flowering habit, it is one of the best and most interesting shrubs for rockeries. There is always a difficulty in selecting suitable shrubs for this part of the garden, many of the most beautiful and free-flowering being, as a rule, too

The Sand Myrtle (*Ledum buxifolium*).

large and strong for the majority of these structures, and it is only such as the above *Ledum* that may be safely recommend to take a place on even the smallest of them. In addition to the *Ledum*, *Azalea amona*, a plant that takes up little room, and though not perhaps generally known, is quite as hardy in the neighbourhood of London as the popular *Rhododendron*. It flowers with the greatest freedom in early summer, and in even our hardest winters it has not suffered in the slightest. *Cytisus purpureus*, many of the dwarf Boxes, a choice selection of the very dwarf conifers, &c., give us a fair variety to begin with. Shrubs, especially those of a dwarf evergreen character, are quite as essential in the rock garden as hardy alpine and other plants. They furnish in the dull months of winter, and help in a measure to hide the bareness which always exists here when the plants are at rest. Much remains to be done in this direction on most rockeries; as a rule, too much attention is given to the development of spring and summer-flowering plants, to the entire exclusion of plants that would give an effect in our rockeries need not be blank throughout the dull season; but, on the other

hand, might be made as interesting, if not as beautiful, as when at their best in summer. All this and much more may be done at the expense of very little extra space, as most of the shrubs mentioned are slow growers, and it would be many years before they required renewing. The *Ledum*, in addition to being evergreen, is, as may be seen in the cut, a beautiful-flowering shrub. The flowers are white and borne in dense clusters in early summer. Like most other American shrubs, it thrives best in a peaty soil, and it will also be found useful as an edging to beds, &c. K.

3928.—Treatment of a Magnolia.—I should say the roots have penetrated into something they do not like; possibly they have got beyond the soil prepared for the tree when planted. If it were planted in the natural soil without any preparation, I should say it has suffered from frost during the last three years. In the former case, I should next October remove the soil up to within 3 feet or so of the stem for at least 2 feet wide, and replace it with fresh decayed turf, leaf-soil, and partly decayed manure. Give an abundant water supply at once, and next year also if dry.—S. P.

—As the tree has done well in previous years, its failing to do so now may be attributed to the soil where it is growing being exhausted, or it may have suffered by the effects of the dry season. If the latter, a good supply of water to the roots might set it right again. I would now put a dressing of manure round the base of the tree, and give it a thorough good watering through the manure. The water will carry some of the fertilising properties of the manure down to the roots. An addition of fresh, good soil may be made in the autumn by digging down at some distance from the tree and removing the useless soil up to the base of the tree, replacing it with a mixture of good loam and manure.—J. D. E.

I am afraid your plant has been injured by the severe frost of the past three winters. It is one of those plants that do not show the effects of cold so soon as some. The best thing you can do to restore its vigour is to take out some of the old soil away from its roots—two barrow-loads would not be too much—and put some good rich earth back in its place. You will require some patience, as in its present condition it will not readily respond to your treatment.—J. C. C.

3926.—Management of a hedge

—By far the best way is to cut the hedge down to within 9 in. of the ground next autumn, especially when it is in the worst condition near the base. Mismanagement at the first was the cause of its getting into a bad state there. So few persons know how to start really well with a Quick hedge. If the plants are not cut down to within 4 inches of the soil at first, seldom ever can such a hedge be considered satisfactory. When allowed to grow 2 feet or more without being topped, branches hardly ever grow from the base—hence it is what is termed "leggy." By all means grub out the Elder bushes, and plant more Quicks in their place—a single row, 4 inches apart. By cutting the hedge down as advised, new growth will be made direct from the base, and a perfect hedge will be had in time; but as it now stands it can never become a good fence. Quick hedges require cutting at least twice every year. This induces extra growths to be made, thus strengthening the hedge.—S. P.

I should say that the best way to strengthen and to thicken the bottom of the hedge would be to "pleach" it, as we used to call it in Wiltshire, or, in other words, to lay it down. Cut some of the upright stems half-way through a foot or two from the ground

with a hatobet or bill-hook, bending the tops down and interlacing them with others, which should be cut clean off at about a yard in height, or, instead, some stakes may be driven in. The whole will grow again, and in time they will make an almost impenetrable fence. Elder is poor stuff, and should be replaced by Quicks or Myrobellia.—B. C. R.

— Elder bushes should never be planted in a Thorn hedge, as they grow too vigorously and the large leaves weaken the Thorn by shading it from the sunshine. I would certainly cut the Elder out and cut the hedge down to within a foot or so of the ground; this will cause it to break out into numerous growths and will lay the foundation of a thick set hedge which will only require good trimming to form an impenetrable hedge. A good Thorn hedge is an admirable fence. It ought to be kept free from weeds.—J. D. E.

— Grab out the Elders and cut back the Thorns to a uniform height of 3 feet or 4 feet, and fill in the weak places at the bottom with Privet.—E. H.

FINE WILD GARDEN PLANTS.

AMONGST the thousands of hardy perennials in cultivation at the present day there are numbers of them which, though they are plants of noble port, are not suitable for a mixed border, but require either a place to themselves, or to be planted in semi-wild situations where they can attain full development, and then they produce a striking effect. The huge *Onopordons* which grow 8 feet to 10 feet high, and other large Composites, such as the various species of *Ligularia*, *Sesuoio*, *Lappa*, *Silphium*, *Veronica*, *Helianthus*, *Eupatorium*, *Mulgedium*, and *Telekia speciosa* (here figured), &c., have a very stately appearance. The large-growing species of the following genera will also flourish well in such a position as this. *Althaea* and *Malve* may be planted here, as also the handsome *Impatiens*, *Perula*, *Phlomis*, *Campanula*, *Verbascum* and *Symphytum*. Climbing plants, such as *Lathyrus*, *Calystegia*, *Tropaeolum*, &c., will clamber over the shrubs and supports in wild luxuriance, all of which tend to make this part of the garden attractive.

W.

3886.—**Substitute for rotten manure.**—I consider it is a point in your favor that you cannot obtain rotten manure. Quite an erroneous idea prevails amongst amateur cultivators respecting the use and value derived from manure quite rotten. What beneficial properties can there possibly be in manure when decomposition has entirely taken place? Simply the shell is left which held the goodness, the violent heat caused by the mass during fermentation necessary to render it in a rotted condition dissipated the ammonia, and it is the ammonia which should be preserved for the benefit of plants of any kind requiring stimulative food. Nothing is better as food for plants than horse-manure, as this contains the ingredients advantageous to successful cultivation. Instead of employing this in a fresh state throw, say, a couple of wheelbarrowfuls into a heap, encouraging the mass to ferment by wetting it if in too dry a state to become heated without. When the mass is warmed thoroughly through turn it over to sweeten it and get rid of a portion of the rank steam. After the second turning the manure is ready for use. In making liquid manure from horse droppings, I should advise that they be put into a sack in a fresh state, adding one peck of soot to every bushel of manure. The sack prevents the solid manure becoming mixed with the water, which would choke the passage-way on the surface-soil in the pots for future waterings. The water soaking through the sack becomes charged with the manurial properties.—S. P.

Wireworms.—A certain trap for these cotton-cake, baited about 2 inches deep, and examined about every three days. I have this year caught scores by this means.—N. Y. Z.

3878.—***Calceolaria rugosa*.**—This *Calceolaria* is a shrubby variety that was formerly much used for bedding, but a variety called Yellow Gem, much dwarfier in habit, has to a large extent taken its place. A few specimens are also much used in some places.—E. H.

THE KITCHEN GARDEN.

LATE PEAS.

It is customary for the compiler of calendar matter to advise the cessation of sowing late Marrow Peas after the middle of June, but instead of these some of the early sorts are recommended to be sown. Doubtless this is sound advice as far as the more northern or cold localities generally are concerned, though if those practising in more favoured districts adhered to it, the chances are not many late dishes of really good Peas would often be forthcoming. I hold that *Ne Plus Ultra* or any other well-tried late sort may be sown as late as the end of June in all southern or warm localities with every prospect of profitable crops being obtained, always provided they are not starved for want of moisture at the outset. In the neighbourhood of Bath Omega is a favourite late variety, and this may be briefly described as a medium height form of *Ne Plus Ultra*. Mr. Coolidge, who has long made a speciality of Peas, sows Omega extensively after the first good rain that may fall during the first fortnight in July, or if rain does not sufficiently moisten the ground, the watering-pot has to be employed. From these rows good late crops

Telekia speciosa.

are obtained, the supplies not unfrequently lasting till near midwinter. Certainly the climate in the neighbourhood of Bath is exceptionally mild, but, all the same, the plan of sowing Omega early in July is well worthy of being given a trial in various other parts of the country. With me the late June sowings of *Ne Plus Ultra* usually hold out till severe frosts are experienced in November, and in addition we also have good pickings from a number of rows of the dwarf *William Hurst*. Either this or the similarly good *Chelsea Gem* may be sown up to the middle of July on the ridges between Celery trenches or on borders newly cleared of early Potatoes with a good prospect of remunerative and greatly appreciated crops being obtained. One great advantage these dwarf varieties have over taller-growing sorts is the ease with which they can be protected from early frosts. If required late they must be protected too, especially if they are growing in other than the highest part of the garden. Branches of Fir or Evergreens or a strip of scrim canvas hung over strings or wires strained well above the Peas will usually prove ample protection. I must also point out that it is next to impossible to sow two or three short rows of dwarf varieties, as they would never attain good crops

ings at one time. From one quart to two quarts of seed may well be sown, the rows running through the centre only of the Celery ridges or else 18 inches or rather less apart on borders of any kind. The practice of

SOWING NEWLY-SAVED SEED of both the dwarf early varieties named and also *William I.* on similar sites is a good one. New seed invariably germinates the most strongly, and a vigorous start is a great gain in the case of late Peas. Too often the old seed produces very feeble plants, and these make but poor progress and fall a prey to mildew. August is usually a very trying month for Peas, and if they are subjected to the ordeal of dryness at the roots as well as excessive heat, it is not to be wondered at if they either crop prematurely or succumb to mildew. Late Peas generally ought, therefore, to have a deep and fairly rich root-run, and the soil so drawn up to the rows as to form a basin for holding the copious supplies of water that ought to be given during August and the early part of September. Very frequently cultivators are misled by appearance. Very rarely indeed do we get enough rainfall during the summer months to keep the roots of Peas sufficiently moist, and it is most unwise to stop watering during showery weather. That is really the best time for watering and also applying liquid-manure, and, in any case, mere dribbles are useless. A mulching of straw manure is never thrown away on Peas, and a thorough roaking should be given where possible. M.

3916.—**Treatment of Cucumbers.**—Procure three boxes each about 2 feet square, three parts fill them with any good soil; first boring several holes in the bottom to allow the water to drain through, and cover the holes with broken bricks 3 inches thick. Put one plant in each, just covering the top roots with soil; make this moderately firm. If ordinary garden soil is used, add one part of horse-droppings or partly decayed stable manure to every three parts of soil. Stand the boxes in the front of the greenhouse, and in the most sunny spot. Fix some wires to the rafters 1 foot from the glass to train the branches on. Do not pinch out the point of the plant until it is 4 feet up the roof of the greenhouse, and not then if side shoots are being freely made at the base of the plant. These should be pinched at the second leaf, repeating the process as growth is made. Syringe the leaves twice daily during fine weather, say, once at 8 a.m. and again at 4 p.m. When the roots show on the surface cover them an inch thick with soil and manure in the same proportion as the plants are growing in. Maintain the soil in a moist state. It is difficult to say how often it should be watered, so much depends upon its character—heavy or light—the position of the house, &c. Do not allow the roots to suffer for want of moisture. This will be the best guide: Probe down a few inches to ascertain its state, and give water accordingly—that which is tepid is the best, as being less likely to give a chill to the growth.—S. P.

— Let the plants grow some 3 feet or 4 feet unstoppped, then take out the points of each. Lateral growths will soon push from the axils of the leaves, and when these have advanced a short distance these will show the embryo fruit on each. Stop these laterals at one joint beyond the fruit, so as to enable this to swell, and when they push into growth again repeat the process as often as may be necessary throughout the season.—B. C. R.

— Let the main stem have a good start before stopping, say 4 feet or 5 feet, or even more if there is room, but stop side shoots as soon as they show fruit, and afterwards stop one leaf beyond the fruit and follow this up all summer, and there will be plenty of fruit if the other treatment is right. The chief requirements of Cucumbers under glass are moisture, shade in hot weather, and plenty of nourishment in the shape of rich top-dressing after they begin to bear.—E. H.

— It is not desirable to grow these in the same house with greenhouse plants. The best way will be to plant them in flower-pots from 10 inches to 12 inches in diameter. When the plants have grown about 18 inches in height, pinch the growing points out. Lateral growths will at once be produced, and upon these fruitful blossoms will soon appear. Stop the lateral

growths again, and the fruit will soon grow large enough to eat. It is not necessary to set the blossoms if the fruit is not wanted to produce seed. The plants require rich soil to grow in, and surface-dressings of richer material afterwards. The plants do better in a hot-bed.—J. D. E.

DWARF KIDNEY AND SCARLET RUNNER BEANS.

The Dwarf Kidney Bean is one of the most useful vegetable grown as an outdoor crop, and it is also most accommodating if cultivated under glass. It is very impatient of cold, and therefore a warm, sheltered situation should be

A good type of Kidney Bean.

chosen for it. Crops of it are often damaged by being sown too soon. The second week in May is a good time to sow the first crop, and a second sowing at the end of May will furnish a supply till Scarlet Runners come in, after which the Dwarf Beans are seldom asked for. The latter should have 2 feet between the rows and 10 inches in the row, and the tall growers 2 feet 6 inches row from row and 1 foot apart in the row. They like a good, rich soil that has been well manured for a previous crop, which is better than rank manure, in which the plants are apt to run too much to foliage instead of fruitfulness. In very hot weather they enjoy a good damping over the foliage about five o'clock in the evening through a fine-roset watering-pot or garden engine. Such treatment strengthens the plants and prolongs the gatherings; it also obviates attacks from red-spider, to which they are liable. For the first sowing Early Prolific is an excellent cropper, and comes in early, and Pale Dan is a good kind for a general crop, with Canadian Wonder for large pods. Runner Beans require similar treatment to the dwarf kinds, with the exception of the distance between the rows, which should be 4 feet apart and 1 foot in the row. They can be grown with sticks in the same way as Peas, pinching out the points when they reach the top, or they may be run up strings. They are a very valuable crop for both the amateur and the cottager. They do not take up much room, and they can be run on strings against beards or a building, on which the old Scarlet, which is one of the best for general cropping, has, when in flower, a fine appearance. Even in some of the most confined town gardens may often be seen Scarlet Runners flowering profusely and bearing pods in abundance. Good types of these Beans are here figured. J.

3935.—Unhealthy Cucumbers.—Dryness at the root, accompanied with an arid atmosphere, would account for the state of the Cucumber-plants. By far the best plan is to root them out and start afresh. Any ordinary garden soil will grow Cucumbers, providing it is fairly sweet and mixed with partly decayed stable-manure, one part of the latter to three of the former. As Cucumbers are moisture-loving subjects, ample drainage should be provided, as stagnation about the roots in any form is bad for the health of the plants. If the soil is 15 inches deep that is sufficient. Fortnightly top-dressings of manure and fresh soil, an inch or so thick, stimulates the plants very considerably. A proper system of pinching in the shoots above the second leaf should be practised, and when the plants are fruiting freely the main

fruit ought to be cut from the end joint, allowing those to develop from the lower ones. Too heavy a crop at one time is not conducive to success, neither is that allowing too much growth to remain on the plants so as to over-crowd them. All the main leaves should have space to develop to their fullest extent. If more shoots are made by the plants than there is roof space, cut some out. Water must be applied freely, yet discriminately; do not give it if the soil is wet, but on no account allow the plants to suffer for want, or the small brown insects—red-spider—which "R. G." complains of on the under side of the leaves, will speedily attack them. Syringe the foliage twice daily, early morning and about 3 p.m.; this tends to promote health.—S. P.

I am afraid your plants are attacked with what is known as the Cucumber disease, for which there is no known remedy. You had better clear out the plants and also the soil, and after well cleaning out the pit, or whatever they are growing in, start anew with fresh soil, and put in plants obtained from afresh source. When so affected the plants do not always give out altogether, as with careful treatment they can be kept alive, and will produce a few fruits. But I think yours are badly attacked with the disease.—J. C. C.

The Cucumbers appear to be infested with thrips, and are otherwise in a bad way. Your idea of clearing them out and starting afresh is probably the best. Before setting out the fresh plants make sure the thrips are cleared out by fumigating rather heavily on two successive evenings.—E. H.

3922.—Beetroot and Celery.—Sutton's "Blood Red" or Pragnell's "Exhibition" are both good kinds of Beet. No time should be lost in sowing the seed in drills 15 inches apart on moderately rich soil. If too much manure is used the Beet is stringy and fibrous. It is a good plan to grow this root on land previously occupied with Celery or Peas. It is useless to sow the seed now during this dry weather in the ordinary way. After drawing the drills well soak the soil in the drill, afterwards sowing the seed. Sulham Pink is the best red Celery for standing through the winter, white kinds are not nearly so good for that season. It is now too late to sow for any other purpose but a winter and spring supply. Sow the seed thinly in sandy soil, just covering it, in a shallow box or seed-pan, placing it in a gentle heat to hasten germination to make up for lost time. When the seedlings are an inch high remove them to a cold frame, and when large enough to handle transplant them out 3 inches apart in fairly rich soil 2 inches thick, laid on a thin layer of rotted manure or leaf-soil, over a hard bed of coal ashes. Into the manure the roots will enter, ensnaring the plants to be lifted with a good ball of soil attached to each, which will prevent a check to growth when finally planting out. If garden space is limited, double rows may be grown to economise space. Dig out a trench 15 inches deep, and 1 foot wide, laying the soil on either side of the trench. Break up the soil at the bottom 3 inches deep; over this spread manure partly decayed, 3 inches thick. Cover this with soil chopped down from the sides of the trench 3 inches thick. This will make the trench wider for the plants; when they are 4 inches high lift them with a trowel, preserving all the roots intact, first well soaking the soil to enable it to cling to the roots. Plant in the trench as near 10 inches apart as possible. If the soil is at all dry give it a good soaking of clear water. Celery is a moisture-loving subject and should not at any time suffer for want of it, or the leaves will be hollow and spoilt. The aim should be to have it firm and with a nutty flavour. Any stint in moisture at the roots will not produce Celery of this kind. Occasional soakings of liquid-manure during dry weather will much assist growth. It is scarcely possible to give too much water during dry weather, but not too much stimulating food or there is a danger of making the Celery rot during the winter, owing to its being too succulent. When the plants are 15 inches or 18 inches high it is ready for the first earthing of soil to blanch the leaves and make it tender. At the base of each plant several small leaves or crowns will push

through and should be pulled off at the time of earthing. Two persons are required to earth Celery properly. The great point is to keep the leaves close together and upright while the soil is filled in about it, if not the soil finds its way in among the leaves and renders the growth crooked and spoilt. Tie a piece of bast around each stalk before adding the soil, afterwards cutting it through with a knife to loosen the leaves. Add more soil as growth proceeds.—S. P.

It is now far too late to sow Celery seed. This should be sown out-of-doors in February or early in March. The plants are now ready to plant out in the trenches. It will be necessary to obtain plants ready to set out if good Celery is desired. The best time to sow Beet is about the middle of April; if it is sown too early much of it will run to seed, and if so late as this the plants will be too small. The Celery seed should be sown in a border of fine rather light soil. Prick the plants out when large enough, and let them be about 3 inches or 4 inches asunder. Plant them out in trenches in very rich soil about the end of May or early in June. Williams' Matchless Red is as good as any. Dell's Beet is very good.—J. D. E.

It is too late to sow Celery now. You will have to buy plants. Beetroot may produce usable-sized roots if the weather is suitable, but it is full late for sowing Beet now.—E. H.

3911.—Rhubarb from seed.—It is mainly a question of culture as to when Rhubarb can be gathered from seedling plants. Probably a few stalks may be picked from plants three years old. Plant the seedlings out next February in deep rich ground 3 feet apart.—E. H.

Mulching Turnip-rooted Celery.—Last year I tried a thick mulching of manure among my Celeric or Turnip-rooted Celery. I found it a great advantage. Besides keeping the ground moist and cool, condition specially favourable to the well-being of Celery, it is an easy matter, even where the soil is fine, to get a good soaking into the soil.—L. C. K.

3925.—Gardening for profit.—As Asparagus does well in the garden, you cannot do better than make a speciality of it. It is under such circumstances a paying crop, and can, if necessary, be sent to a distant market, as it is easily packed. Seakale is another crop which is deserving of more attention, especially where there are facilities for forcing, such as frames and manure. Try to find out what is most in demand in the market near. Fruit, such as Strawberries, might pay to send to Rhyd, and other of the rising watering-places near.—E. H.

I do not think anyone can tell you exactly what to grow that will return the most profit without knowing the locality and the

Bean "Canadian Wonder."

facilities there are at hand to get rid of the produce. In the first place, the clay soil is not an advantage, except for certain permanent crops. If I was starting in such a case I would first ascertain what crops the ground would be likely to grow best, and of these I would select ones of a permanent character that require the least attention. If Asparagus does well, that should be one of them. Seakale might be another. Among fruit I should say that Strawberries, Raspberries, Gooseberries, and Red and Black

URBANA-CHAMPAIGN

Currants may be tried. The cost of labour in moving about a clay soil for annual crops you will find will be a serious item in the expenditure. The subjects I have mentioned when once planted give but comparatively little trouble.—J. C. C.

OUTDOOR PLANTS.

LUPINES.

THESE, like *Aquilegia*, *Verbascum*, and similar plants, may be had in abundance by simply growing them together in masses. In a large bed, where most of the varieties in cultivation are grown, innumerable varieties, in the way of colour and form, may be had in the course of a few years. Even the old *L. arborea*, which ought to be yellow, seems to be influenced by the bright and varied colours of the others, and produces some tinged pink and others blue. The polyphyllus group in the same way varies to a great extent, even in the same plant. Some few, however, of the annual kinds, when received straight from their native localities, are really handsome plants, amongst which may be mentioned *anhransus*. It produces large spikes of the most beautiful ultramarine-blue flowers imaginable; *nanus*, which grows about a foot high, has purplish-blue and white flowers; also *coccineus* (1½ feet high), rose-bloss, deep red, and white; *digitatus*, deep blue and white, an extremely fine variety; *guatemalensis*, white and purplish-red (2 feet); *albo-violacea*, violet and white (2 feet); *canaliculatus*, pale purplish-white and blue (2½ feet); *venustus*, lighter coloured than the above, and with larger leaves; *mutabilis*, handsome large foliage, pink and white flowers, very fine (2 feet); *Dunnettii*, pink and white, dwarfed, and with smaller leaves than *mutabilis*. There are also, though rare in a true state, *Hartwegi*, *Crikshanski*, *Menziesii*, &c. All the *Lupines* are easy plants to cultivate. They grow well in ordinary garden loam, and succeed even in town gardens. They ripen seed plentifully, and, if sown in the open early in April, the young plants will commence to yield flowers from the beginning of June until August or September. They are natives chiefly of Mexico. One of the best of perennial *Lupines* is *L. polyphyllus* (horn figured). K.

The Mountain Cornflower.—The varieties of *Centaurea montana* are very vigorous and hardy plants. If rather coarse they are showy, and several colours are available, ranging from purple-rose to white, and the pink is pretty when out. In smaller gardens the varieties are not usually much seen, but they are more pleasing than the type, the colours are softer and more refined. The plants grow between 1 foot and 2 feet in height, and throughout the summer, the flowers appear, being in shape like those of the common Cornflower but much larger. One sees in the markets large bunches of the flowers, and they are grown especially in quantity for cutting, as they last well in water. The plants are easily raised from seed nor they may be divided for increase. I make mention of them as they are good things for amateur gardens, readily grown, bright, free, and hardy.—V. C.

Pyramidal Rockfoil.—When in a small plant-house, only just heated to keep out severe frost, I was charmed with the effect produced by about twenty-four species in full bloom of this Rockfoil, named *Saxifraga pyramidalis*, mixed with the *Blue Campanula persicifolia*. It was a lovely contrast of colour, and obtained by judiciously associating plants of easy culture, such as could be grown by amateurs with a small house. Amongst the many Rockfoils this is one of the most precious, its great pyramidal spikes of pure white flowers lasting in beauty for a considerable period, and by placing them with the Bell-flower the effect is charming. *S. pyramidalis* is not difficult to grow, and, as a rule, when the plant has flowered and ripened seed, it dies. It is a Pyrenean plant, and forms handsome glaucous rosettes, and the flowers appear in a pyramidal-shaped spike, the stem purplish in colour, and it will rise nearly 2 feet in height. A thin stick may be put to it to prevent accident. On the rockery this Rockfoil is quite at home if planted in a perpendicular stone, in some chink in which it can send its roots and the rosette reveal its true beauty. A colony may be thus established and

prove of extreme interest and beauty. Those who cannot thus grow it should be content with pot-plants, and raise seedlings, although these will vary; but that lends interest rather to thus propagating them. Watch for the seed to ripen, and, when gathered, sow them in pots or shallow pans, which must be well drained, and filled with light, loamy soil, mixed with fine brick-rubbish, an excellent material for Rock-

Lupinus polyphyllus.

foils. Do not fill the pan or pot quite full, and sow the seeds very thinly on the surface, lightly cover with fine soil, and water gently with a rose watering-pot. If too heavily watered the seed will be washed away. Then cover the pan with some dark glass to promote germination, and remove the pan to shady corner. After germination give a little air, remove the glass, and the after treatment assists in transference, when of sufficient size, to other pans, and then to the rock garden, or to larger pots, if required for the greenhouse. The soil in the summer must be kept moderately moist, and, remember, in growing them in pots that they are quite hardy.—T.

Day Lilies.—These are good plants to grow where choicer things fail. They are very hardy and robust, succeeding well in uncongenial spots, and always bloom well. A group of them is handsome, and they, like many other plants, dislike constant disturbance at the roots. When once established leave them alone, and use in the first place good soil, moderately rich, deep, and away from trees. The autumn is the season to put them in the ground, and it is money well spent to provide a mulch of manure in spring to assist them to produce plenty of flowers, although this is not essential. The results are finer, however, from this treatment than from any other. There are some excellent variegated kinds, the leafage of attractive colour, and the flowers are very brightly marked. The best kinds are *hemerocallis Dumortieri*, the flowers of an

orange-yellow colour, and they appear as early as any, bearing several on the erect stems. *H. disticha* is of note, and there is a double variety, of which the flowers are yellow, with a tinge of brown colour in it. *H. flava* blooms early in the summer. The stem rises between 2 feet and 3 feet in height, the flowers rich yellow, and very fragrant, whilst they are of use for cutting. Then one may choose the narrow-leaved *H. graminifolia*, the growth very dwarf, and the flowers yellow; *H. Thunbergia*, yellow, and rather late blooming; *H. fulva*, also late, the flowers orange-bronze, and without fragrance; and *H. Kwanso*, of which the variegated variety is useful. These are the finest of the family, and their easy culture renders them of much value for all gardens.—V.

A note on Herbaceous Spirææ.—Few classes of plants are more charming than the Spirææ, shrubby and herbaceous, and of the latter section about six kinds are worth growing in all gardens. These would comprise the following: The Goat's-Beard Spiræa (*S. Aruncus*) is a beautiful flower, and a group of it is effective. On the higher parts of the rockery, in the border, or grouped on the lawn, this Spiræa makes a fine show with its feathery spikes of creamy flowers. It grows about 3 feet in height, more in very favourable spots, and the foliage is pinnate and handsome. It may be steadily increased by division. When in full bloom *S. Aruncus* is of extreme beauty. Another charming Herbaceous Spiræa is *S. palmata*, of which there is a good variety. The flowers of the former are bright crimson, both of flattish heads, and the plant blooms freely by the side of water. It is also grown in pots, and succeeds well under such conditions. One gets quite a group in such kinds as *S. lobata*, which is a relative of *S. palmata*. The common name of it is Queen of the Prairie. The growth is dwarf, and the flowers are of a rosy colour, borne in large bands. Another name of it is *S. venusta*. The border will be enhanced in beauty by planting this fine kind. Then there is the common Drupwort (*S. Filipendula*), a native plant too familiar to describe; but there is a double variety also well known, which must be mentioned. The flowers are quite double, creamy-white, tipped with red. Everyone who cares for flowers knows the familiar Meadow Sweet, very common by the side of ditches. Its name is *S. Ulmaria*, and there is a double variety that is a feature, also a variegated kind worth growing, the foliage attractively coloured. These Spirææ are also easy to grow, hardy, and will succeed in border, or by the side of shrubs, as well as by the margin of water. *S. palmata*, by reason of the bright colour of its flowers, and *S. Aruncus* are perhaps the two most beautiful.—V. C.

3910.—Climbers against an east wall.—Get some of the stronger growing climbing Roses, such as *Gloire de Dijon*, *Waltham Climber No. 1* (the flowers of which are of a rich red colour, very sweet), *Chestnut Hybrid*, *William Allan Richardson*, or *Reine Marie Henriette*; but *Gloire de Dijon* is the best, and then the *Waltham Climber*, *Chestnut Hybrid*, or *Reine Marie Henriette*. There is a large selection of things for the wall, besides Roses. The Winter-flowering *Jasmine*, *Honey suckles*, *Clomatis*, especially *C. Jackmani*, *Yves* in variety, *Crataegus Pyracantha* (brilliant, with its bright berries in winter and its flowers in early summer), *Vines*, *Dutchman's Pipe* (*Aristolochia*), *Passion-flower*, *Wistaria*, &c.—C. T.

3912.—Plants for a shaded wall.—I am afraid Roses would not do much under the shade of a forest Chestnut-tree. Few things will, except *Iris* and *Honey suckles*, and if these were planted alternately, and each confined to its own portion, which might be limited to 3 feet, the effect would be good. Make a good border to plant in.—E. H.

Few, if any, Roses would do much good in such a situation. *Honey suckles*, *Ivy*, and *Jasmine* are almost the only things that will thrive to any extent.—E. C. B.

If the wall is not very shady, you might try such strong growing climbing Roses as *Gloire de Dijon* and *Chestnut Hybrid*, first well preparing the soil—they will succeed well—or some of the beautiful *Bourbon* and *Noisette* kinds, which bloom freely. The shoots may be trained to the *Horse Chestnut*, and they would then hang down and make a charming picture in the garden. Such a position as this would suit well also the many *Ivies*, which delight in partial shade, and make vigorous growth, especially if the situation is rather moist. A good strong growing, rich green-leaved

variety is Emerald Gem, which quickly makes headway, and you might also select some of the better variegated varieties, such as *H. aurea elegantissima*, *H. marginata elegantissima*, *H. angularis aurea*; but I have seen the popular *H. madeirensis* so crippled by winter frosts that I would not care to recommend it. Very beautiful, especially in the winter, is *atropurpurea*, the leafage of which is bronzy-chocolate in colour, and very handsome. Glymi, the leaves large and of a glossy character; Leesman, silver, a prettily variegated kind, and the strong-growing *H. Rægneriana* may be also recommended. You could, however, try the *Roses*, or a few *Ivies* as well. They are very pleasing in contrast, if the growth of the *Ivy* is not permitted to interfere with that of the *Rose*.—C. T.

You do not say what aspect the wall is. If it is not north I should not fear to plant some of the strong-growing Hybrid Perpetual *Roses* to cover it. Such good growers as *Mign Charta*, *Madame Noobry*, *General Jacqueminot*, *Gloire Lyonnaise*, and climbing *Victor Verdier* would do well in a good *Rose* soil. But are you sure that the roots of the *Chestnut-tree* would not reach the *Roses*? If so I would advise planting some more vigorous-growing *Roses*, such as *Gloire de Dijon*, the *Garland*, and *Félicité Perpétuelle*.—J. C. C.

3915.—Plants for a small pond.—A small pond would look very pretty planted with *White* and *Yellow Water Lilies*, or even the *White Lilies* alone. If it is decided to have more variety, plant *Alisma plantago* (*Water Plantain*), *Botomus umbellatus* (*Flowering Rush*), *Hottonia palustris* (*Water Violet*), *Sagittaria angustifolia* (*Arrow Head*), *Pontederia cordata* (*Picerele*), *Typha angustifolia* (*Cat's Tail*), *Stratiotes aloides* (*Water Soldier*). Round the banks may be planted *Iris Paend-Acorus*, *I. sibirica*, and several others. *Lythrum salicaria*, *L. purpureum* *compositum*, *Phormium tenax* (*New Zealand Flax*), *Osmunda regalis* (*Royal Fern*), *Primula sikkimensis*, *Carex pendula*. Most of these can be purchased in pots, and will only require planting in good soil near the water's edge. The aquatics should be planted in mounds of good soil put under the water. They soon get established.—E. H.

3913.—Growing Tobacco.—I believe Messrs. Carter, of High Holborn, have published a pamphlet on this subject. It is easy enough to grow the plants, but I understand that the leaves do not possess the same strength or virtue as those produced in a warm and sunnier climate. Then it appears that the "sweatieg," drying, and subsequent preparation of the leaf are most delicate matters, of more importance than the actual growth, while, lastly, the Government, instead of encouraging, did their best to check and stifle what might have proved a remunerative industry, and so it has had to be relinquished as a "bad job."—E. C. R.

The cultivation of this plant in England is very simple. Sow the seed in a hot-bed early in March. The plants should be pricked out in boxes, and treated just like half-hardy annuals. About the end of May the plants may be set out, 4 feet apart, in rich, deep soil. They each require a stout stick to support them, and with good treatment they will produce immense leaves by the end of the season. Remove all flowers and side growths. The reason it is not grown for profit is owing to the Act of Parliament which limits its culture to a small number of plants. It might, I think, be grown profitably but for this.—J. D. E.

It has been, I think, pretty conclusively proved that Tobacco cannot be profitably grown after paying duty in this country by Messrs. Carter and others. Even suppose it could be grown the quality would be so inferior that no one would buy it. That, I believe, was the result of the trials a few years ago.—E. H.

3934.—A small town garden.—Where the mistake was made was in not burying the turf deep enough, so as to kill the Grass. Rotten turf is splendid stuff in a flower or any other bed, but it must be buried at least 6 inches below the surface, or it will grow again to a certainty. *Roses* do not, as a rule, thrive to any extent in a town garden; but if any will succeed it is *Gloire de Dijon* and *Aimée Vibert*. Standards succeed best in small town plots, and the beds must be made very rich with old manure, leaf mould, decayed turf, &c.—B. C. R.

As in removing the turf you will probably disturb the flowers, you had better sprinkle

the surface with some salt where the Grass appears, but enough salt to make the surface white in colour will destroy the Grass. In doing this you may also injure some of the plants, for which there is no help. It is for you to decide which will do the most injury. It is very clear if it is left where it is without anything done to it the Grass will come through and spoil the growth of any plants growing near it. With regard to preparing soil for *Roses*, a good deal depends upon the character of the present staple. If this is an old garden you had better take away the earth from the bed 18 inches deep and put in its place the same thickness of good loam. If loam is not available, stir up the present soil to the depth above mentioned and mix with it half-a-barrow load of rotten-mannre to every square yard of surface. Twelve good *Roses* for standards would be *Earl Dufferin*, *Princes Camille de Rohae*, *Alfred Colomh*, *Margaret Dickson*, *Mrs. J. Laing*, *Mme. Gabriel Luizet*, *Merveille de Lyon*, *Captain Cbriety*, *Paul Neyron*, *General Jacqueminot*, *Francois Michelon*, and *Eclair*. Some good hardy Climbing *Roses* will be found in *Gloire de Dijon*, *Aimée Vibert*, *Sir J. Paxton*, and *The Garland*.—J. C. C.

3929.—Pinks losing colour.—The lacing, as it is termed, disappears, leaving the coloured centre only, unless the plants are well cultivated in good soil. Old plants will not always retain the lacing, nor will young plants put out in the spring and planted in poor soil. To get good laced *Pinks*, the cuttings, or, to use a technical term, "pipings," should be put in as soon as they can be obtained this month. When the young plants are large enough, which will be in September, plant them out in rich, deep soil, and badly-laced *Pinks* will be the exception, and good ones the rule. Planting them near white *Pinks* would make not the least difference.—J. D. E.

The laced *Pinks* should be renewed from cuttings annually, and planted in the beds not later than October to keep the lacing right. It is not likely that White *Pinks* growing near would affect them in any way, but the long continued drought would very likely have considerable influence.—E. H.

THE BEST STONECROPS.
SEDUM SPECTABILE.

This (here figured) is the finest of all the tall-growing sorts, and a handsome plant in every way. It is beautiful from the time that it

OUR READERS' ILLUSTRATIONS: A fine Stonecrop (*Sedum spectabile*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Galsford, Ollington, Worthing, Sussex.

crowns peer above the ground in spring and develop into rigid shoots, clothed with broad, glaucous leaves, till the last flowers fade late in autumn. The flowers, borne in a dense, broad, flat corymb, which terminates the shoot, are of a rosy colour and last quite two months. In a cutting they last nearly as long, and the shoots root in the water, whilst if before the leaves open the shoots are cut and dibbled several into

a pot, they root and flower and look very attractive. It withstands cold or heat, wet or drought, and is, therefore, a most accommodating plant. K.

Doronicums.—May I supplement the notes of your correspondents in *GARDENING*, June 3rd, page 190, as one or two of them give erroneous information? There are at least a dozen *Leopard's Banes* natives of Europe, and half-a-dozen more of Western Asia. Two are reputed to be British, but probably are not indigenous. The history of the fine variety known as *Harpur-Crewe* is this: It was given to me and others by the late Mr. Harpur-Crewe not long before his death under the mistaken name of *D. Clusi*. I sent a plant to Kew for identification, where it was pronounced to be a variety of the native *D. plantagineum*, and it was named *D. plantagineum* var. *exceles*. This name was cruelly long for gardeners, so I distributed it largely after Mr. H. Crewe's death, under his name, which it still bears. It is not, as stated on page 190, a form of *D. austriacum*, but is probably a hybrid, as I have never been able to find a fertile seed upon it. Mr. Harpur-Crewe thought it originated in his garden. The species *D. austriacum*, a name often erroneously given to *D. caucasicum*, is seldom seen in gardens, being very capricious in its tastes. It is grown in large quantities, and is very showy in Mr. Paul's hardy plant nursery, close to Broxbourne Station. I have had good plants from these three or four times, and they have always died within a year. I cannot find out the cause. *D. caucasicum*, often wrongly called *D. austriacum*, and the closely allied *D. Columnae*, with their dwarf habit and bright-golden flowers, would be excellent early spring plants if they were not so liable to be disfigured when in flower by spring frosts. Many other *Doronicums* are not in cultivation, simply because, being inferior to those we have, they are not wanted.—C. WOLLEY DOD, *Edge Hall, Malpas*.

3877.—American Bellbine or Bindweed.—I do not know of a plant by this name, although our common *Bellbind*, *Convolvulus sepium*, is a native of America, so perhaps the plant is *C. sepium*; but there is a plant called the *American Bell-flower*, *Quamoclit vulgaris*, so possibly this is the thing. The *Quamoclit* belong to the same order as the *Convolvulus*, and

are for the most part half-hardy annuals. Two good kinds of them are *Q. coccinea* and *Q. hederifolia*, rapid growing plants, that will quickly run up a moderately high trellis, the flowers scarlet in colour. They may be grown like half-hardy annuals, and the seeds may be sown later in the spring in the open.—C. T.

3878.—Centauria pinnatifida.—The *Centaurias* will make a suitable edging for

Scarlet "Geraniums." They will not fit in so well with Alternantheras, except as centres, and for that the growth is rather too rough and coarse, though they may be used in connection with *Ilue Lobelias*, either in mixture, or the *Lobelias* may form a broad band round the *Centaureas*.—E. H.

— You can use the smaller plants as an edging to a bed of scarlet, crimson, or pink "Geraniums," etc., or, as you say, as a centre (the larger plants) to a mass of Alternantheras, but they do not go well with Golden Feather or the *Mosebryanthomum*, as the contrast is not sufficiently marked. A pretty way to use them is to plant them alternately, both ways, with *Heliotrope*, *Blus Ageratum*, or with reay or salmon-pink "Geraniums" or *Begonias*. These silvery leaves go well with almost anything else of a rich colour, except yellow, which is not distinct enough; but some of the prettiest effects I have ever seen were produced as above.—B. C. R.

— This is a most useful bedding plant, and its silvery leaves tone down too brilliant effects, and when used to break the formality of a bed, which is perhaps too flat, few things are better to use. It is excellent for beds filled with very bright colours, and the hardy nature of the plant is in its favour for such work, whilst the foliage does not then lose its distinctive character. A very handsome bed I saw last year was filled with *Lobelia fulgens* as the central feature, the *Ageratum* the groundwork, and this *Centaurea* and Tufted Pansy Skylark formed the edging. It goes extremely well with the *Ageratum*. You must not get too many variegated things together, otherwise the effect will be spoilt.—C. T.

3928.—Bedding plants.—I have used the Fish-bone Thistle (*Chamaepeuce Cassabona*) as dot plants, or covered over with the other plants named in carpet bedding, and they make a nice change.—E. H.

A SMALL FLOWER GARDEN.

3932.—First, get the soil into thoroughly good order, and if the garden is new, although the matter may appear simple, thoughtful consideration is necessary. A glaring fault in most gardens, large and small, is the size of the walks. One walk is usually sufficient. It is impossible to get much pleasure from a garden when the chief thing in it is a hard, uninteresting gravel path, twice as large as necessary, and usually adorned with Moss or weeds. Always have the path at the side of the garden, and it need not be wide, just of sufficient width for one person to walk upon with comfort. The idea is to get as many flowers as possible, and every inch of space should be jealously preserved. A model garden I saw laid out recently. The space was small, but made the most use of. A narrow path ran down one side, so as not to intrude on the general view, and the centre of the space was laid down with good turf, on the outskirts of which were oval beds, arranged after no set order, to prevent formality. A broad border skirted the lawn, and the plants disposed in groups, a mass of *Michaelmas Daisies*, *Helianthus*, and so forth to create a good effect in colour. Rarer things were labelled, but labels are ugly, only necessary when the plant is unfamiliar. In very small gardens a walk running round the house suffices, and the remainder of the plot may be given up to flowers. Many very beautiful spots may be seen even near such large and smoky cities as London, full of colour in the summer and autumn months, through judicious use of suitable things and planting them in bold clumps. A colony of *Daffodils*, *Tulips*, or Tufted Pansies is far finer than a sparse sprinkling of a medley of subjects planted simply to gain variety. There is charm in variety, but not when it is procured at the expense of effort. One will soon discover what plants succeed best, one locality agreeing with certain things better than another. Half the battle is to know the most suitable things, not attempting to coax into respectable growth delicate little alpine that please the eye in the exhibition tent. Many select their plants at a show, and take a list of things that are often difficult to cultivate and entirely unsuited to the locality. The soil, if not good, must be made so by fresh material. It is absurd to expect beautiful flowers to spring from a mixture of brick ends and builder's refuse, and unless there is a thorough foundation on a good loam, it is vain for healthy growth. Bedding

then becomes a worry, money is thrown away, and nothing presented to view except marked by ill-health, but all these discomforts are in nice cases out of the soil the outcome of insufficient preparation of the soil. When not made up of refuse it has often been undisturbed for many years and become sour, unfit entirely to support beautiful flowers. Thorough trenching of the ground will be necessary, not, however, bringing to the surface any of the crude clayey material, which plants do not relish. When the digging is finished, if possible, let the soil remain rough

Flowers in simple bunches.

for a time, so that rains and the air may set upon it, and bring it into a sweet condition. If the work is done in the winter, one has the benefit of frosts, which is an excellent pulveriser, and it is for that reason the soil is left in ridges in all gardens during the winter. Follow out the same plan in the small plot, and one will be rewarded by plants of finer growth. Another wrinkle is, always as far as possible to get

Good plants to commence with, and much vexation is saved by procuring in the first place the best materials. Of some things, it matters little; a few plants of such things as the Perennial Sunflowers quickly making headway in the poorest soils. Always plant well, not when the ground is sticky, but moderately dry. A great error amongst amateurs is loose planting, and the cause of their plant's ill-health is not obvious until they are pulled slightly, when they easily lift out of the soil. Unless planted firmly, it is hopeless to expect respectable growth, but avoid ramming the ground too hard. The smallest gardens may be made gay with flowers from the time of Snowdrops until the Christmas Roses open their white blooms to the wintry sky, if a judicious selection is made, not necessarily of expensive things. Avoid little heaps of stones, called "rockeries," which are nothing of the kind, but simply heaps of burrs or stones, utterly without beauty and incapable of sustaining plant life through the small amount of soil that the "pockets" hold. As regards edging plants, those for the margin of the beds, read my note in GARDENING, of June 3, p. 196, from which you get the names of the best plants for the purpose. A few other good things are *Daffodils*, *Tulips*, *Hyacinths*, *Crocuses*, and other spring Bulbs, which should be planted in October—the *Daffodils*, if possible, in September. Carnations would succeed well near the sea, and you might plant now for the summer *Tuberous Begonias*, *Pelargoniums*, and other summer bedders, just to give a little colour until the autumn. Put in also some early-flowering *Chrysanthemums*, good bits of *Michaelmas Daisies*, and Perennial Sunflowers to bloom in the autumn. I can also recommend besides the above a variety of the *Sneezewort* named *Achillea mongolica*, with large, pure white flowers produced in summer; *Adonis vernalis*, spring flowering, yellow; *Peruvian Lily* (*Astrovermeria*), *Anemone japonica*, and the white variety, give free-blooming plants in early autumn, the flowers large and white in variety but rose-coloured in the type. *Aquilegia glandulosa*, *Campanulas* in variety; the yellow-flowered *Coleopsis laucolata*, *Perennial Lark-spurs* or *Delphiniums*, the *Lyre-flower* (*Dielytra spectabilis*), the *Fraxinellas*, white and purple rose, *Doronicums*, *Erigeron apocianum*, *Gypsophila paniculata*, *Day Lilies*, *Evening Primroses*, *Herbaceous Plovers*, and the beautiful trailing kinds, *Saxifragea* variety, *Rudbeckia speciosa*, *Sedum spectabile*, *Globe-flowers*, *Herbaceous Lobelias*, the varieties *fulgens* and *Queen Victoria* in particular, the leaves deep glossy chocolate and the flowers brilliant crimson; Tufted Pansies, Lilies, *Rosa* in variety

if the soil is deep and not too sandy, *Iris*es of many kinds, and such shrubby things as the beautiful *Fuchsias Riccartoni*, which I have often seen in superb flower near the sea; the *Rose Acacia*, selecting a not too exposed spot; *Eacilonia macrantha*, which succeeds well by the sea, the leaves deep-green and the flowers crimson. *Hydrangeas* would thrive, I should think, and many more things than those enumerated here. But you must read carefully GARDENING, as from time to time selections are given, and any good plant recommended may be added. See what kinds of things do well in other places. The finest lot of *Lilium chelodonicum*, the scarlet *Martagon*, I ever saw, was against the sea, near Soerborough, and it is surprising also how well annuals thrive if the position is not too exposed. This is a comparatively small list, but sufficient have been mentioned to give you a good start. C. T.

— Seeing that the whole of the space is surrounded with trees or hedges, near which nothing will grow, owing to the ground being full of roots and partially shaded as well, you cannot do better than have a walk all round, and fill the centre with flowers and a few choice low-growing flowering shrubs and Roses. The walk may be five feet wide, and then you will have space enough left to make the centre a very interesting feature. You will have room enough to grow a few good varieties of *Delphiniums*, *Michaelmas Daisies*, *Panicles*, *Campanulas*, *Lilies*, *Gladioli*, *Gorman Irides*, &c. Other interesting herbaceous plants will be found in *Spiraea Aruncus*, *Inula glandulosa*, *Fryngium amethystinum* (*Sea Holly*), *Everlasting Pea*, *Phlox* in variety, *Pyrethrums* (double and single), *Rudbeckia Newmansii*, and many others. Some pretty flowering shrubs will be found in *Hypericum patulum*, *Oleari Haasti*, *Althaea frutex*, *Daphne Mezereum*, and *Karria japonica*.—J. C. C.

HOUSE & WINDOW GARDENING.

SWEET FLOWERS IN SIMPLE BUNCHES.

ONE of the many good reasons for having one sort of flower in a bunch by itself is that it is so easily thrown out and renewed when its first freshness is gone. The White Pinks, as shown in the engraving, are just placed in the glasses as they were picked in the hand, giving the least possible trouble. An elaborate arrangement that takes some time is often put off till the flowers are beyond beauty both for sight and smell—a matter worth remembering in high summer-time, when flowers fade as quickly as they come.

WINDOW BOXES IN SUMMER.

IN arranging a window-box, it is well to consider the aspect in which it is to stand, and also whether the surrounding atmosphere be that of a city. *Tuberous Begonias*, which are now amongst the most favourite plants for a window, do not grow well in London smoke, although they will make a magnificent display if the air be pure. *Tropeolums* of various kinds are most suitable for town boxes, for they are not particular as to this, and their specially bright clean-looking foliage and brilliant blossoms make a bright hit of colour, very refreshing amidst the masonry. *Tom Thumb Tropeolums*, with carmine blossoms, look well with an edging of bright-blue *Lobelia*, and a line of *Marguerites* behind them, the clear red, white, and blue being very harmonious. This selection has also the merit of being extremely cheap. Taller *Nasturtiums* may be used to climb up the sides, meeting in an arch at the top, or *Tropeolum canariense* (*Canary Creeper*), with which few creepers can compare for quick growth and elegance. Ivy-leaved "Geraniums," of a clear pink tint, carefully avoiding those of a magenta hue, are very suitable for trailers in the front of a window-box, especially if they are placed alternately with plants of *Saxifraga sarmentosa* (*Mother o' Millions*), which form a most beautiful fringe of rich-bronze foliage, hanging 2 feet down, on which the bright blossoms of the *Pelargoniums* are well set off. The lovely plant (*Saxifraga sarmentosa*), with delicate lace-like, white blossoms, is not nearly so common as it should be; it is invaluable for many positions, such as baskets, rockwork, &c., as well as window boxes. Another good trailer is *Moneywort*, with long straight fringe, covered with

golden-yellow flowers. This, too, alternated with the Saxifrage, is singularly beautiful, and the back of the box can be filled in with handsome purple Petunias, contrasting charmingly with the golden-yellow frings, with Pink Pelargoniums, while Zonal Pelargoniums are suitable for the back row, or White Fuchsias. No other red flower should be used, if possible, if the effect is to be thoroughly harmonious. Where Tuberosus Begonias can be used, it is well to select those of a red tint, so they blossom at least a month earlier than the paler varieties. "Habit" also should be considered—i.e., the shape and size to which the plant grows, for some Begonias are of a tall, straggling habit, very unsuitable for a window box, while others, with neat shape, covered with rather drooping blossoms, are just as perfect. In the list of our best Begonia-growers may be found a selection of plants especially fitted for "basket" work. These are excellent too for a window-box, and few plants are so satisfactory, unless, indeed, the aspect be a very hot, dry one, when their foliage is apt to suffer. *Nisrembergia gracilis* makes a most suitable fringe for the front of a box full of Begonias, or the useful Mother o' Millions may be used. For creepers at the sides, which can be trained on string, strained between rather long nails, with good effect, for it is scarcely visible, *Lophospermum scouandens*, a handsome Vine-like plant, with large pale-pink flowers, or *Tropaeum "Fire-fly"*, an intense scarlet blossom with dark foliage, may also be selected. *Cacalia Creeping*, *Major Convolvulus*, or *Eccremocarpus scaber*, too, are all satisfactory in this position. In a north aspect Ivy should be permanently trained up the sides, and English Ferns should be grown in the front of the box, leaving room behind them for a row of brilliant scarlet Zonal Pelargoniums, which can be brought on in a south window until they are a mass of bloom, lasting for some weeks when plunged in a north window-box. When, however, these Pelargoniums go out of blossom, they can be taken out, given a rich top-dressing, and set again in a sunny window, while their places are taken by a second set of Pelargoniums or other plants. *Calceolarias*, *Fuchsias*, and many other flowers do well for a few weeks here in the height of summer, if well grown in pots, and plunged to the rim. All window-boxes must be well supplied with water and good compost, this being renewed each spring. Liquid-manure too, once or twice a week, will help the plants when the box becomes full, for they have little room for their roots, and the hungrier plants are apt to starve the rest. Window-boxes need to be thickly planted, gaps of 4 inches or 5 inches being usually sufficient between the plants, and they should receive a mulch of rich compost over the surface whenever the plants appear to need more soil. Vigorous growth will thus be secured, especially if the plants are thoroughly watered every day.

f. L. R.

FUCHSIAS FOR A WINDOW.

THESE beautiful plants, which have for some years been somewhat neglected, have lately become more sought after, and are now largely used for bedding purposes as well as for specimen plants. Few plants are more suitable for cultivation in a window, but they must have plenty of sunshine, as well as air, and a low window suits them best. They are almost continual bloomers, if well supported, only needing to be slightly cut back, and given a small shift, with light, rich soil, good drainage, and plenty of water, to throw out a fresh mass of blossoms many times during the summer. Their chief enemy is thrips, which is apt to attack their foliage if they are kept too dry, or need more nourishment than they can get. Directly the tiny black and white spots which indicate this insect pest appear on the under parts of the foliage, they should be sponged off with soapy water, and if this course is persisted in for a week or two the enemy will soon disappear. The plants should, at the same time, be repotted, or, if in full bloom, supplied with soot-water or other liquid-manure twice a week, when they will recover their strength and throw out fresh growth. Some of the best of the new varieties are as follows: *Countess of Aberdeen*, pure white, rather dwarf; *Shirley Hibberd* with handsome dark blossoms, double; *H. McStainley*, brilliant-carmine, with purple centre; *Dorothy Fry*, semi-double, white and crimson; *Miss*

Lizzie Vidlor, red and mauve, very fine. Many of the older varieties are also well worth growing, and these are very cheap either in small pots or as cuttings. *Fuchsia* cuttings will grow well in a window if given sandy soil, pure sand, or even in a bottle of water. They must never be allowed to want water (if in pots), and are best grown in a cutting-box, which insures damp air, unless grown in water only. A "cutting-box" is easily arranged by procuring a common deal box about a foot deep from the grocer's, and placing in it 3 inches or 4 inches of fine ashes. Having placed the pots containing cuttings in the box, water the ashes from a rosed watering-pot, and cover the whole with a piece of glass. If this should be broken or in two or three parts, all the better, as it is then more easy to supply the light ventilation the cuttings should have. The glass should be removed each morning, wiped, and replaced, all falling leaves or decay of any kind being carefully removed, or they may rot up mildew, and so destroy the young plants. As these become established and begin to grow the glass should be removed gradually, and the little plants placed in small pots as soon as rooted, with leaf-mould, loam, and sand. By means of turning the plants constantly and cutting the points back into shape, handsome plants may be secured, which will need frequent repotting, according to their growth and strength.

f. L. R.

FOXGLOVES AND FERNS FOR THE DECORATION OF ROOMS.

THERE are few more magnificent plants than well-grown Foxgloves, and when the white variety (*Digitalis alba*), or still better the handsome Spotted Foxglove (*Digitalis maculata*), are selected for cultivation, we can hardly have too many of them. Seed sown now will bring plenty of plants for next year, and these can be placed in flowering position out-of-doors, either in October or during the following March. But

but they should not be exposed to too much sun, rather preferring a shady place, and they need good rich soil. They should not be removed to the house until the first few blossoms are open, when they will do well in a window, especially if plenty of air be afforded them. For a balcony or verandah, few plants are so handsome, and they can be induced to throw up a quantity of shorter racemes of blossom later in the summer, by means of cutting the central spike directly it has done flowering, and removing all seed-pods as soon as the blossoms fade. To group with these plants, there is nothing so good as English Ferns, which can also be grown out-of-doors throughout the year. An area is an excellent place for these Ferns, for they enjoy the cool shade there without draughts or direct sunshine. English Ferns have of late years received the attention which is their due, for there are many handsome varieties amongst them, and a few such as *Hart's-tongue* (*Scolopendrium vulgare*) and the beautiful little *Devonshire Fern* (*Asplenium Adiantum-nigrum*) are evergreen, forming excellent decorative plants in winter also. The *Lady Fern* (*Athyrium Filix-femina*) and several of the *Laetrea* group, with the commoner *Male Fern* (*Laetrea Filix-mas*) are very suitable for grouping with Foxgloves in a room. They should be grown in separate pots or boxes if possible, or a few of the smaller varieties may be placed with the plants of Foxgloves in a good-sized box. Drapery of a rich tone, such as crimson or maroon, will look well to hide the box or pots, and the whole effect will be singularly elegant.

f. L. R.

FERNS

ASPENIUM FLACCIDUM.

THE plant here figured is one of the forms of *A. flaccidum*, which is one of the most variable Ferns with which I am acquainted. The figure here given is taken from a specimen sent home

Asplenium flaccidum odonites.

those who have no garden may still cultivate Foxgloves in large pots or boxes containing a group of three or more plants, for they are hardy, only requiring slight shelter (for the sake of their handsome foliage, which is sometimes injured) during the severest winter weather, when the plants can be lifted into an out-house, or covered with boards, or a piece of matting raised a little from the leaves by means of sticks or stones. Any place out-of-doors, even the leads of a town-house, where not too smoky, will grow Foxgloves,

from New Zealand, its native country, so that no modification has come about through cultivation. The common form of *A. flaccidum* in English gardens produces long pendulous fronds some 3 feet or more in length, the pinnae being distant, narrow, some 6 inches long, deep-green in colour, and viviparous. It is well suited for growing in baskets in the greenhouse. The form, however, now under consideration is quite unsuited for basket purposes, being erect in habit, and thick and leathery in texture, thus proving that, in spite of what may be said

to the contrary, such a variation deserves a distinct name for garden purposes. The form in question was a few years ago common in cultivation; it is an evergreen greenhouse plant, well adapted for a nook in the rockery, and being so different in habit to the pedunculate form, it may with perfect safety be planted in juxtaposition with it. As a pot plant this form is not one of the most attractive *Ferns*, its rigid habit being against its forming a graceful specimen, but when potted out it is a very charming subject, and well deserves the attention of all readers of *GARDENING*. W.

ORCHIDS.

CATTLEYA SCHROEDERIANA.

IN a brief note from my whilom acquaintance, "Humphrey Clinker," comes a flower of this rare plant, introduced about ten years back by Mr. Sæder, and thus named by Reichenbach, although since it has been reduced to a variety of *C. Walkeriana* by some authors, the last-named plant being found by Gardner in Mirias Gerais, in Brazil, some fifty years ago. This Orchid is said to be spread over a wide area, but I am of opinion that there has been far too much lumping of plants together, and far too little notice or thought taken of its habit and style of growth, &c., and various plants which resemble *C. Walkeriana* in wanting the side lobes to the lip are all classed with it. My friend "Humphrey" does not say whether his plant flowers upon the same growth with the leaves, but from the appearance of the flower I think it does, and, if so, it is the plant named above; but *C. Walkeriana* does not, but it makes a separate growth, which alone bears the flowers, and which dies soon after the flowers have faded. *C. dolosa*, which is classed as a variety of *C. Walkeriana*, produces its flowers upon the same growth as its leaves, whilst *C. nobilior* makes a separate growth, but its flowers are larger, and the side lobes of the lip are large enough to entirely cover the column, with the edges reflexed, and the same thing occurs with *C. dolosa*, whilst in *C. Walkeriana* the side lobes are reduced to half the ordinary size, and in the flower now before me they are merely small appendages, and these differences incline me to the belief that far too much lumping together has been done. However, "Humphrey" having got this plant will wish to keep it, and if it is what I take it to be, it is extremely rare and is worth taking every care of. If he has it in a pot it should be kept just damp through the winter months. It should be kept in a temperature which does not fall below 60 degs., and it must not be allowed to suffer from want of water, because it cannot withstand unheralded either an excess of cold or an over drying. I myself should prefer block culture for this Orchid, but more care is then necessary to keep the plant properly supplied with all it requires. I should like to know from friend "Humphrey" if my surmise is correct—that the plant sent out flowers from the top of the shoot-bearing leaves. MATT. BRAMBLE.

THE BLUE VANDA (V. CÆRULEA).

THIS species, whenever or wherever seen, is always a favourite, even although not of the best blue variety. Such was the case upon the present occasion, when "Snares Milles" writes, telling me that she saw a plant of this at the Temple Show, exhibited by the Messrs. Lewis, of Southgate, and she thought it charming, and she wants to know where she can get one, where it is from, and how she can manage it? It is now over fifty years since this species was first seen in the Khasia Hills by Griffith, and whenever seen it causes the heart to glow with a desire to possess it; but when obtained there is usually found some difficulty in its management. When Griffith found this plant first, he tells us in his "Itinerary Notes," it was in the month of November, and the climate was really delightful, reminding one much of England, which, however, I should imagine was not England in the month of November, for then it is not usually very delightful. It blooms in its native country soon after the rainy season, which is about the end of September or the beginning of October, and it is in the late autumn it usually flowers, with or under cultivation, so that "S. M." who does not care to visit flower shows at such a late

has not before had the opportunity of seeing it, for the plant referred to as shown by the Messrs. Lewis was quite out of season. I heard the other day from a celebrated Orchid grower that he had just imported a fine lot of these plants, so that there will be ample opportunities of getting the species, and now for the best means of growing it. Well, there are two sources for this plant, I am told, the first is already named, and from this source I have myself had many hundreds sent to me, but I cannot say that anyone of these turned out a very first class variety, but the Messrs. Low and Sons, of Clapton, and Mr. Sæder, of St. Albans, have been fortunate enough to import some very fine forms, having great breadth of sepals and petals, and of a fine rich blue colour, and these, I am told, come from the Burmese territory. Naturally it is an Orchid that is exposed to great deal of rain, sunshine, and wind, and even in the cool season to frost, so that it appears to be a difficult plant to accommodate in the Orchid-house at home, and to treat in anything like a natural manner, but I have seen it do best and flower most profusely when grown in a hanging-basket, in an ordinary stove-house, near the roof-glass, but near an open ventilator, so that there was a constant supply of moisture rising from the plants below, an abundance of air, and a full supply of sunlight to allow of its revelling in; but care must be taken and not let the leaves get herded with the sun. It must be remembered the plants have a glass covering, which they have not upon their native hills. In the winter season they should be reared in the Odontoglossum-house, and at no time during the growing season should the temperature exceed 85 degs., and at this time the night temperature should fall 20 degs. or 25 degs., so that it will be seen that at no season is an excessive heat necessary; and this often puts me in mind of my old master's saying when a boy. He had bought a lot of imported *V. cærulea*, placed them in the hottest part of the East Indian-house, keeping them constantly very wet; but as this was in the early days of its introduction, we then know nothing of its natural surroundings—knew absolutely nothing of cool Orchids, and even now that we do know we yet have a difficulty in keeping this plant very long in a good state of health. But my friend "S. M." should invest in a few plants. They are not now expensive, and if she succeeds only for a few years with them she will reap her reward. MATT. BRAMBLE.

DENDROBIUM AMENUM.

FROM "Gerald Walker" come flowers of this plant for a name, which I here give, and as it is a very pretty kind and a very free bloomer, I will call my readers' attention to it, more especially as it is a species that grows and does well in a low temperature. It is a plant which has been known for upwards of sixty years, but which never reached this country in a living state until about twenty years ago, when it appeared in Mr. Bull's nursery at Chelsea. Some plants of this kind were shown at the recent Temple exhibition, but they were in a poor state, and not well done, certainly not in such a condition as to induce an amateur to take up with it. The plant grows on the Himalayas at some 5,000 feet elevation, so that it may be placed in the warm end of the Odontoglossum-house for the greater part of year, but in the growing season it requires more sun than those plants, and therefore may be removed with advantage to the Cattleya-house or an ordinary stove; but after the growth is finished, it should be placed in a light spot in its usual abode, and less water given it; but I do approve of subjecting this plant to severe drying, for this would subject the slender stems to extermination, and instead of their producing their brightly-coloured and very fragrant flowers, produced usually upon short spikes two and three together, but sometimes singly. MATT. BRAMBLE.

The Moccasin-flower.—The North American Lady Slipper (*Cypripedium spectabile*) is one of the finest of hardy Orchids, and not difficult to grow either if the soil and position are suitable. It grows 18 inches in height, and has large, charming coloured flowers, much more attractive than half the tropical and island *Cypripediums* that need a stove for their

culture. The Moccasin-flower is white as regards the sepals and petals, and the lip or pouch, as it is called, is bright-rose, the colour varying in shade in individuals, sometimes almost crimson, and again white without a trace of any tint, whilst the leaves are bold, vigorous, and of a good green shade. It may be grown in pots, and is pretty in the greenhouse. The soil must be a mixture of peat and loam, not too heavy, and good drainage is necessary, also shade. A hot sun is hurtful. In the open the Moccasin-flower thrives perfectly well in a moist, almost boggy, corner, where the *Trillium* thrives. In such a spot, sheltered from keen winds, strong sunshine, and perfectly cool, the plants make good growth. It is a pleasure to see this beautiful Lady in full bloom in the open.—V. O.

British Orchids.—In reference to collecting these plants, our good old friend, "Matt. Bramble," on p. 197, says "The plants must not be taken up now;" in which statement he is both right and wrong—right as regards the careless collector, for whom no time is right, but wrong as regards the true plant-lover, who is always tender and careful in handling his pets. For the latter the best of all times to collect the British Orchids is when it is in flower; then a selection can be made of such varieties as please and the remainder left for someone else. The method that will ensure success is to get round the plant with a strong blade (a table-knife is an effective instrument) of your pocket-knife, about 2 inches from the stem, and 4 inches or 5 inches into the ground, then lift the plant without breaking the ball, and it will look exactly as though it had been turned out of a 4-inch pot, and will travel well without the plant flagging in the least. Last June I collected several specimens in flower in the manner indicated 200 miles away from home, which were not planted for a fortnight afterwards in the quarters they now occupy, and where they are in full flower.—T. L. C.

SOWING BIENNIALS.

THIS is the time to sow seeds of many beautiful flowers that require a longer season of growth than annuals. The following are especially deserving of culture: *Alyssum saxatile* compactum succeeds well treated as a biennial, although it stands good for several years. Sow at once and transplant as soon as large enough. Its rich-golden head of flowers is very striking. *Antirrhinum majus* (Snapdragon) is a fine old plant that makes a good display in mixed borders. Canterbury Bells are amongst the finest of tree biennials; sow in beds and transplant in autumn to their flowering spots. *Digitalis* or Foxglove, a stately plant, looks well in beds of shrubs or towering above hardy Ferns. Forget-me-not, one of the most lovely flowers in the garden; sow at once and transplant at any time in beds, borders, or edgings. Heartsease or Pansies, although increased in many ways, are best treated as a biennial; sow now in a cool, shaded place, and as soon as the seedlings are large enough transplant. Honesty (purple and white), is valued for its early display of flowers, and especially for its silvery seed-pods that are very valuable for decoration; should be sown at once. *Silene* compacta, with its rosy-pink mass of bloom, is very valuable for spring bedding; sow in August. Stocks (Brompton), that are the glory of cottage gardens, should be sown now and pricked out in a sheltered place before winter. Wallflowers (single and double) in distinct colours are each general favourites that no garden is complete without them. If not already sown do not delay, or the plants will not have time to get strong before winter. J. O., Gosport.

Spiraea aristolobea.—Although not so well or so widely known as its near relative, *Spiraea japonica*, this is in reality a most lovely flower, and when it becomes better known will, I feel sure, enjoy as wide a popularity. It requires similar treatment—viz., rich soil and abundance of root moisture, as drought in any stage of its growth is fatal to it. As a decorative plant it is of the highest value, as large plants can be grown in small pots, and the spikes of bloom are much longer than in *Spiraea japonica*, and the foliage larger and more spreading. Do not think it is so well adapted for early

forcing; in fact, I value it more for coming in after *S. japonica* is over. Potted up in winter and kept in a cool-house, it will be in full bloom about the middle of May, and anyone not having yet given it a trial should include it in their list for next year.—J. G., *Hants.*

FRUIT.

VICOMTESSE HERICART DE THURY STRAWBERRY.

It is to be deplored that so useful and generally excellent a Strawberry as this is should have such a very long name. I think if it were generally written of as "Vicomtesse" only, everybody would recognise it fully. It is not generally known that many years ago, when the late Mr. Thomsen was at Chiswick, he, on the instruction of the Royal Horticultural Society, paid a visit to the French Strawberry gardens and brought over to Chiswick plants of a number of the best varieties. Of all these, the one now mentioned is the sole survivor and affords another illustration, if such were needed, of the undoubted fact that of all the seedling

no breadth endures longer than two years. A short life and a merry one for Strawberries seem to be Mr. Norman's motto at Hatfield. Certainly, he states that the soil there will not produce a good crop the third year, and it is rare anywhere that it pays to allow plants to stand longer when really fine fruits are needed. That in some deep holding soils breadths kept clean and heavily mulched with manure will endure for several years and produce fine crops is certain. Elton Pine will do so, as I have found even in soil that was far from being rich, and give a wonderful lot of fruit for ordinary use and preserving. The plan adopted at Hatfield with Vicomtesse naturally necessitates the putting out of large quantities of runners to cover a given area annually, but then there is the undoubted advantage that every part of the ground is at once fully occupied. After all, the chief consideration is how can the finest fruits be secured? That is an element in Strawberry culture which requires especial prominence.

3930.—Seedling Grape Vines.—With- out the berries from which the seed was obtained

young wood made the previous year, and whether it has had a chance to ripen well. Some Grapes, such as the Muscate, Alicante, and Gros Colmar require quite a hot-house tempera- ture to ripen the young wood and the fruit well, and seedlings from them would do no good in a greenhouse. Black Hamburg and the Musca- dine Grapes ripen well in a greenhouse, and seedlings from such would have the same charac- ter. The only chance to obtain fruit upon the seedlings will be to encourage good strong growth, and expose it well to the sunlight.— J. D. K.

— The probable cause of the seedling Grapes not fruiting was unripe wood. Seedlings would require more ripening than old-established Vines. A little fire-heat would have made a great difference. Keep the young growth stopped back this season, and do not prune too hard when the leaves fall, and they will fruit next year.— E. H.

CULTURE OF MONSTERA DELICIOSA.
THE house described by "S. R." should suit the *Monstera* very well. The main elements of success in the culture of this tropical fruit are heat, light, and moisture, and, provided these necessary condi- tions be one and all supplied, success will be ensured. Any form of training may be adopted which will bring the plant well up towards the glass. It may be made to cover a portion or the whole of the back wall trellis, or, what is preferable, it may be trained round forked tree stumps, a system which suits it admirably. It may also be grown in a tub, but I should prefer planting it out in a good body of fibrous peat and loam in equal proportions, which should rest upon a good drainage of brick rubble. Thus placed, unlimited supplies of water may be given in hot weather, and the fruit will be fine in quality and abundant. Although the *Monstera* will thrive in a low temperature, it will not develop its true character as a fruit-bearing plant, unless a brisk growing heat be maintained during the spring and early summer months. Other plants should not be permitted to crowd it, or in any way obstruct the light from it, and only just enough shade should be given to prevent scorching.

Monstera deliciosa.

Strawberries put into commerce during the past twenty-five years, very few have been found qualified to out older sorts from popular favour. The Vicomtesse still remains one of the most popular for pot culture; perhaps of early kinds it is the one most widely grown for forcing. It sets freely, is fairly easily managed, produces when the trusses are duly thinned very good-sized fruits of fine form and rich colour, and though not first-class, is perhaps one of the best-favoured of all early forced varieties. With respect to outdoor culture of this variety, Mr. Norman, of Hatfield Gardens, strongly admires the variety, preferring that and Sir Charles Napier to any other two sorts. He treats the Vicomtesse largely as a biennial, for he selects all the best runners not required for forcing and plants them in good, deep, well-manured soil so thickly as 12 inches apart all over. The breadths are kept well hoed, and in the late spring are well mulched with long manure litter. Then the fruits after there has been a good set are hard thinned down to a mere few to each plant, and thus a very fine crop is ensured. So soon as fruiting is over, three-fourths of the plants are cut clean out, and the rest have ample room to develop that season into fine clumps. The following year they crop heavily, then are cut out and re-planted

were fertilised with some good kind, most likely the seedlings named will be useless. Raising Grapes from seed is a risky business, and one seldom practised. If "G. L. Butler" persists in growing those now in hand I should advise that they be placed in large pots with a view to cramp the roots somewhat to induce them to give a hunch or two to prove their worthiness of further trial. Vines growing in pots require abundance of moisture at the roots.—S. P.

— Seedling Vines are generally several years before they bear fruit; but, of course, a good deal depends upon the treatment they receive. If skilfully managed they would bear fruit earlier. When I was interested in this subject I used to graft the seedlings on the spurs of established Vines, and they invariably bore fruit the next year. Amateurs, of course, cannot do this. I am afraid there is nothing else for you to do but wait. Meanwhile, do not encourage the seedlings to grow too vigorously, and keep the lateral growth pinched back close.—J. C. C.

— Seedling Orpington Vines fruit as freely as the ordinary named varieties when they have grown strong enough to produce thick well-ripened growths. The fruiting or non-fruiting of Vines depends upon the character of the

3910.—Fruit-trees against a north wall, &c.—Morello Cherries succeed the best of any fruit against a north wall, and almost any kind of Plum will flourish there too, if I except Washington, which is rather a shy cropper against any wall but that with an eastern exposure. Red and White Currants succeed capitally, and will hang much longer there than on the open bushes. In many gardens a few trees are usually planted in this particular spot with a view to lengthening the season of these fruits. Gooseberries may also be satisfactorily managed for the same purpose as the Currants. One of the best kinds for late use is Warrington, more commonly called Rough Red. The skin being tough, the fruit will hang long after any other sort, and really improves in flavour with keeping. Gloire de Dijon is far and away the best Rose for an east wall. Aimée Vibert, the Yellow Bankian, and the China Rose, of which Cramoie, Supérieur is the best, succeed really well. As regards climbers, many kinds will flourish against an east wall. For quick growth and a dense covering, there is nothing like Irish or Ragneriana Ivy. Ampelopsis Veitchi gives an abundant leaf crop, but is deciduous during the winter. If in the south, Escallonia macrantha, Ceanothus divaricatus, and Garrya elliptica will stand almost any winter. Sweet Jessamines, Honeyuckles, and Clematis Jackmani will flourish anywhere. Good soil and abundance of moisture at the roots during hot and dry weather are the essentials to success.—S. P.

— Morello Cherries and hardy cooking Plums are the most profitable trees to plant against a north wall. The spaces between the fruit-trees may be filled temperarily with Red and White Currants. Plant in autumn. Such hardy Roses as Gloire de Dijon, William Allen Richardson, Cheshunt Hybrid, and Jaune Desprez, will do very well against the east wall. Other climbers suitable are Ampelopsis Veitchi, Cotoneaster microphylla, Jasminum nudiflorum, Honeyuckles in variety, Pyreantha (Evergreen Thorn), Pyrus japonica, and variegated Ivies.—E. H.

— Morello Cherries and Black Currants are almost the only kinds that do really well on a

north aspect. Some Plums will fruit fairly well, but as a rule the fruit is both late and extremely acid. On an east wall you may plant Gloire de Dijon, the Boursault, and many other Roses, Psefifora aculeata, and P. Constance Elliot (white), Clematises in variety, the Fiery Thorn, and, in fact, almost anything will do well, especially if protected a little on the north by trees, shrubs, or buildings.—B. C. R.

—The Morella Cherry and Victoria and Golden Drop Plums do well on a wall with a north aspect, and so does that well-known Apple, Lord Suffield. East walls are not the best aspect for Roses, as they are very liable to be attacked with mildew in such a position. Gloire de Flijon will do as well as any. Sir Joseph Paxton, rose, and Almés Vibert, white, are also hardy and free-flowering. Amongst other suitable climbers I may mention Clematis Jack-mani, White Jasmine, and Honeysuckles.—J. C. C.

3920.—**Treatment of Peaches.**—The young shoots which break away from the current year's wood are termed laterals or sublaterals, and they should be pinched back to one leaf when quite young. But if the trees are young, and there is wall or trellis space to cover, train some of the best of them. There will be time enough to get the wood ripe, and it will tend to equalise the flow of sap, and reduce the strength of the leaders.—E. H.

—What "Anxious" terms accession shoots are usually known as laterals; they should be pinched back to one joint. If the shoots are numerous, and these with laterals as thick as the small finger, I should advise their removal to make room for those of the size of an ordinary Cedar pencil. This latter is a fair size for Peach-shoots to give a full crop of fruit the next year. Extra strong growths do not give much fruit, often none at all. The main point in Peach culture is maturity of the wood; this cannot be secured if the shoots are overcrowded. A space of 4 inches should at least be allowed between the current season's growths. Do not stop the leading shoots if the growth all over the tree is pretty well balanced, but if it is not these strong shoots should not only be stopped, but if depressed they would be all the better, as the flow of sap would be all the more equalised over the tree. The strong shoots may be the result of giving too much manure to the roots or these latter may need checking. The month of October is the best season for that detail to be carried out. Root pruning means covering any strong fibreless roots that have rambled away some distance from the tree. Pruning them within 3 feet of the stem will force them to make fibre, which are really the feeders. Do not supply any kind of stimulative food; clear water is sufficient. Keep the foliage free from insect pests of any kind by timely syringing with soapy water.—S. P.

—The production of lateral growths so freely show that the trees are in good condition. There will be time enough yet for such growths to form blossom-buds. The leading point in their culture is to thin the shoots out well, so that they are not overcrowded, and do not stop the small or slender growths, for they are usually so studded with flower-buds that the only leaf-bud is that produced at the point of the young wood, and if this is cut off the growths will die back. The very strong shoots ought to be stopped, and they will at once produce laterals, which must be treated as advised above.—J. D. E.

3936.—**A lean-to Peach house.**—The description points to a bad attack of aphid, for which the best remedy is Tobacco, either in decoction or powder; but if this were the case you could scarcely help seeing the insects, and no mention is made of any. I can scarcely imagine it possible for trees to get into such a condition without the agency of insects, though, as even the normal leaves are yellow and mottled, the roots are evidently unhealthy as well. Do the trees get enough water? These are moisture loving subjects, and the weather of the last three months has been most trying to such. Peaches are often planted in a far too light soil, and overdrained, whereas they thrive best in a damp and moderately stiff material. Here the soil is a strong loam on a clay subsoil, yet Peaches planted without any drainage whatever thrive wonderfully, and unless attacked by

insects make a very vigorous and healthy growth.—B. C. R.

—The trees appear to be in a most deplorable state. Removing them in the autumn and replacing with others that are healthy seems to be the most satisfactory method of bringing about better results. In the meantime they might possibly be improved by attention. Dig down to the roots and see if the soil is too wet or too dry. If the former, withhold water until a change is effected in the soil. If it is dry give several thorough soakings of clear tepid water. Do not syringe the trees for a few days until signs of improvement take place if the border should be found in a wet state, providing, of course, the leaves are not covered with red-spider. To that case give the trees a thorough drenching with water overhead, applied with force through a hand syringe. Place a handful of sulphur in a 3-gallon can of water, thoroughly wetting every leaf. Repeat this four times a week in the evening, on other nights use clear water. Should the young leaves be infested with black-fly dip the points of the shoots in a strong solution of Tobacco-water, well washing them with clear water next morning. Ventilate freely when the weather is favourable, avoiding draughts of cold air. If "Percius" decides to replace the trees with new ones I would advise him to that point later on in the year, say September.—S. P.

—There is something very wrong in the treatment of the trees referred to in this inquiry, and it is very probable that that something is dryness at the roots; at any rate, the information supplied points in that direction as one of the causes of failure, and the description of twisted and distorted branches further proves that the mismanagement has been going on for some time past. Nor are the trees so free from insects as the querist seems to suppose, or the foliage would not be crinkled and bunched, as it is green-fly that is the cause of these distortions. I advise "Percius" to make up his mind to destroy all the trees in the autumn, and after taking away the old soil and putting fresh in its place to furnish the house with other trees. Meantime, give the present trees sufficient attention to ripen what few fruits they are carrying. I must, however, remind you that ordinary young trees would not have died so quickly if they had been well managed, and, therefore, if you do not improve the management you had better not make any further attempt at Peach-growing.—J. C. C.

Strawberry "Noble."—How well this fine variety (barring the flavour) has withstood the intense drought and heat! Some plants at one end of a long bed planted with various kinds present a marked contrast to the rest, being laden with fruit, while on the others there is scarcely any. This is on a strong clayey loam, and even on light dry land on the opposite I have seen this variety heavily laden with fine fruit, so that it seems to thrive on any soil. In pots under glass it has also fruited better than any other variety.—B. C. R.

CHRYSANTHEMUMS.

BOUQUETS AT CHRYSANTHEMUM SHOWS.

How seldom do we meet with a really good bouquet of Chrysanthemums at the autumn exhibitions. It is surprising how content some exhibitors are to go on year after year in the manner of arrangement of the flowers. Nine out of every ten of the bouquets exhibited outside of the regular trader are simply a mass of Chrysanthemums and Ferns huddled together without any regard to selection of colours or taste in arrangement. The main aim appears to be to see how many blooms can be crammed into a 15-inch space, that generally being the limit allowed for the diameter of each bouquet. Another aim appears to be that of so placing the flowers that not a single flower shall stand outside of the line of its neighbour. Some exhibitors arrange very carefully one large yellow incurved bloom in the centre, making the next row quite even all round with perhaps a rose or lilac colour. How often do we see blooms of the large flat-bone section employed for bouquet-making. Instead of the lumpy incurved blooms and the

stiff Anemone flowers, why cannot exhibitors use more freely such elegant varieties as Source d'Or, M. Garnier, Mme. Lemoine, Avalanche, M. W. Holmes, Mrs. J. Wright, and Bouquet Fait? All the varieties named give flowers of a semi-drooping character, are not heavy in build, but light and graceful when arranged as they ought to be. A few blooms of such bright coloured sorts as Cullingfordi, for instance, when effectively placed do much towards brightening up a bouquet. No variety appears so suitable as Source d'Or for either bouquets, vases, or parasols. The fault appears to lie mainly in two things—wrong selection of blooms and the want of method in preparing the flowers before making up the bouquets. It is surprising what a difference is made by fixing a small piece of wire to the peduncle of the flower. When the flowers are treated in this way they can be placed exactly where wished. There should be no pretence to formality of arrangement; the lighter and looser the flowers are arranged the better they look. The spaces between the flowers can easily be filled up thinly with suitable greenery. Maiden-hair Fern and Asparagus plumosus are both suitable. Every bouquet should have a base of greenery of some sort, nothing being better than the Asparagus named. B.

3927.—**Pigeons' manure for Chrysanthemums.**—I should prefer to use this manure in a liquid form, after the pots in which the plants are to flower are full of roots, rather than to mix it with the soil in a dry state. Manure from fowls or pigeons is very strong, and when it becomes wet it swells into a much larger bulk, and is liable to burn the roots of the plants when they come in contact with it. To make liquid-manure will be a simple affair. Place the manure in a sack, to prevent its mixing with the water, as in that state it would seal up the pores on the surface for future waterings. When put into a sack, and soaked in a tub, holding, say, 40 gallons of water to every peck of manure, useful liquid can be made. This is a safe and economical manner of making liquid-manure. Given to the plants three or four times weekly, pigeons' manure will prove a good stimulant. If the manure could have been mixed with the loam two months before being used for the final potting, the rank strength would have passed away, and the manurial properties have permeated the soil, but as no time should be lost in potting the plants I advise using it in liquid form later on.—E. M.

The Variegated Hop.—Humulus variegatus, or the White and Green-leaved Hop, is a very pretty addition to the list of climbers or creepers that are now so much in use for covering arbours, arches, trellises, or walls that are so unsightly in villa suburban gardens, but which, by the aid of creepers, may be made to play a very considerable part in the attraction of small gardens. Everyone is familiar with the Common Green Hop, and this one has the additional merit of variegated leaves, thereby giving more variety to the collection, and as it comes true from seed there is little difficulty in getting a stock of it. Climbers of this kind can hardly be overdone, as their graceful, twining habit of growth renders anything like stiff formalism impossible.—J. G. Jants.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 8d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, 60s., 65s. 12s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 6d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Editions, 1s.; post free, 1s. 6d.

INDOOR PLANTS.

LESCHENAUTIA BILOBA MAJOR.

ESQUIRIES come from a "Young Gardener" as to how he shall grow this plant? I am not surprised that its lovely deep flowers caught the eye and caused him to purchase it, for there are not many gardeners now living that remember seeing the grand specimens being brought to the exhibitions at Chiswick by Mrs. Lawrooce, of Ealing; Mr. Green, of Chesham; and many others. These plants were gems of the first water, far exceeding anything that can be grown in a 48-pot. Leschenautias are generally considered hard to cultivate, and I do not think in and about London it would be found possible to grow them, as in my young days, but you, away down in Hampshire, should be able to secure a good atmosphere suitable for them. One of the worst enemies is damp in winter, to avoid which I need to always keep the plants well up to the glass, and to have them placed in well-ventilated houses, so that a constant removal and renewal of the atmosphere was maintained, and unless this is well attended to the shoots will become mouldy and unhealthy. These are soft Heath-like plants, and they do not like to be exposed to the open air during the summer time, or rather, I might say, without mass of protection; but if fixed in the summertime they do like all the fresh air that blows; but their tops cannot withstand any rough treatment, so that I used to have these plants moved into the open air every genial day, and placed under cover again each night. This, when the plants become large, was attended with some risk, so that I had a framework made, which I could run over them at night, and wherein I had some other choice plants, such as Erica Massoni, and some others, and in this way I used to keep them well ventilated, and without ever exposing them to cold currents of air or to wet. They should be potted in well-drained pots, and as much care bestowed upon this as is done with any Orchids, being for soil good fibrous peat, made sandy, potting firmly, soil watering carefully and regularly, never letting the roots suffer for want at any time, nor upon any account to become "sogged" by overwatering. This is particularly to be noticed in the winter, and in dreary, wet, or dull, heavy weather a fire should be lighted, and extra air be put upon the house, having everything in good condition by night. Three of the best kinds are given below, and, when well grown, these plants are lovely in the extreme, and fit for any place or any situation where they may be used without accident: *L. biloba major* (lovely rich bright blue), *L. Baxteri* (of a rich bright salmon-red), *L. formosa* (rich vivid scarlet). J. J.

3909.—Treatment of *Lilium Harrisii*.—When the plants are out of bloom the leaves remain green for some time afterwards, and they must have a fair supply of water at the roots until the leaves become yellow, when dryness at the roots is necessary, else the plants will again start into growth. When they have passed through the season of rest repeat them. I do this in September. The treatment afterwards is to plunge the flower-pots in which the bulbs have been potted over the rim in Cocoa-nut fibre refuse. I protect them from heavy rains and as soon as the plant has pushed out of the ground an inch or two it should be placed in a glass-house.—J. D. K.

— Give plenty of water to keep the growth green till it ripens naturally. This means that the plant should be gradually dried off. It will do very well plunged outside in Cocoa-nut fibre, or even on the border.—H. H.

3918.—Painting hot-water pipes.—Mix lamp-black with linseed-oil to the consistency of paint, and coat the pipes over with it, using an ordinary paint-brush, except the evaporating-troughs; these should have two coats of paint; lead or stone colour is best. The continual filling them with water is apt to rust the iron if they are covered with the first-named mixture. If the pipes themselves are coated with any lead paint the pipes do not give off the heat as freely as through the lamp-black and oil.—S. P.

— A mixture of boiled linseed-oil and lamp black is much the best thing for this work. Tar or black varnish is injurious and destructive to plant life.—D. C. H.

— There is nothing better for covering than lamp-black and oil. Anyone can apply it, and it is perfectly harmless to vegetable life.—R. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by affixing, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

3911.—Ferns and out flowers.—Will someone kindly tell me which are the best-keeping Ferns (other than *Adiantums*) for mixing with cut blooms?—L. K. W.

3915.—Anemones at Mentone.—Will someone kindly tell me the names of those lovely pale-pink and scarlet Anemones which grow so beautifully at Mentone, Cannes, &c.?—E. H. N.

3916.—White Campanulas.—I am anxious to grow single White Campanulas for greenhouse work. Can seed now be sown? What is the right kind to buy? Do they flower the first year?—S. P.

3917.—Chrysanthemum seedlings.—I shall be much obliged if someone would give me a little advice as to the culture of Chrysanthemum seedlings, which are now about 1 inch high?—J. W. P.

3918.—Good lawns.—What is the best method to produce good lawns? To destroy weeds without damage to the Grass? Is it to use acid or any similar "destroyer" for the weeds?—G. W. J.

3919.—Unhealthy Tomatoes.—I am trying to raise Tomatoes under glass with heat. Very many are going blotchy and black. Will someone kindly inform me in what way I fail?—J. J. SMITH.

3920.—An unproductive border.—Will someone kindly tell me what I can do with a hard, stony border, facing south, under Fir-trees and Laurels? Will any sort of flowers do well in such a place?—R. W. H. AINS.

3921.—Cardoons.—Will someone kindly tell me how to treat Cardoons? I got some seed from France. The plants are about 4 inches high now. Are they to be treated like Celery? Full instructions will greatly oblige.—AMATEUR.

3922.—Evergreens under Limes.—I should be much obliged if someone would name the best evergreen shrub for a background to grow underneath Lime-trees? They are wanted to grow to the height of 10 feet. Clayey soil.—A READER.

3923.—Sulphur for mildew.—I find putting sulphur on the hot-water pipes is recommended as the cure for mildew on Grapes. Will anyone kindly tell me how to use sulphur for the same purpose in an unheated greenhouse?—LEOPOLD DROWN.

3924.—*Philadelphus microphyllus*.—Can I propagate this with cuttings, or must it be layered? I quite agree with "V. C.'s" opinion of it, as being a most charming small deciduous shrub; the sprays of bloom are naturally formed shoulder sprays.—W. B.

3925.—Powdery mildew.—I shall be glad if anyone will tell me what proportion of lime-manure I can put in a 35-gallon tub of water to make liquid manure for Cucumbers and Tomatoes, and is it better than that made from the cow-dung and stable?—DEMI-PIQUEUR.

3926.—Moss litter for Mushroom-beds.—I should be much obliged to any one who will kindly inform me if the much talked-of moss is well adapted to prepare a Mushroom-bed with? And, if so, a few hints how to set about it would be most acceptable.—P. SANDERSON.

3927.—Fruit-trees and insects.—My wall fruit-trees are infested with insects, which destroy the fruit before it is ripe. The Peschee, Nectarines, and Apricots suffer most. Will anyone kindly give me a recipe for solution to destroy them to destroy these pests?—W. B.

3928.—A rusty plug in a boiler.—I shall be glad if anyone will tell me how I may remove the draw-off plug in my Horse-shoe boiler, which I have inadvertently allowed to rust in? I have tried a wrench, but cannot move it. Will it be necessary to have it bored out?—DREYFUSIER.

3929.—Carnations, &c.—Which plants of the Carnation *Souvenir de Malmaison*—old or young—are the best for winter and early spring blooming? My gardener tells me that the reason the flowers are so small (not much larger than the common Carnations) is that they are young plants.—E. H. N.

3930.—Malmesion "Carnations".—Will anyone kindly tell me what to do my "Malmesion" Carnations? The flowers are green and hard in the middle, and the plants are always covered with green-fly. I have a vinery where I keep them in the winter. Is that too hot for them?—M. H. A.

3931.—Blood as manure.—As I have the option of having the blood from a slaughter-house I should be glad to know if I could use it with advantage on such plants as Chrysanthemum, Cucumbers, Tomatoes, Vegetables, &c., and what would be the percentage of water to be used with it?—W. SPARD.

3932.—Allotment garden.—I have an allotment garden of ten rods in the neighbourhood of Kilburn, which I have just started turling. Will someone kindly tell me whether it would be best for me to burn the turf or let it lay in a heap and rot? Also, what vegetables I could grow this year? The earth is good maiden mould. I have plenty of stable-manure.—BONUS.

3933.—Flowering plants for a conservatory.—Will someone kindly let me know what are the best kinds of flowering plants for a lofty conservatory, where the Palms are grown, also Ferns and Moss on the walls? These are syringed every day to keep them growing. By doing this the plants are always damp. What kind of plants would flower best in this kind of house?—S. F. C.

3934.—Treatment of Indian *Asiatic*.—I should be much obliged if anyone would give me some information as to the treatment of *Asiatic*? I have had two—in the house during winter—and spotted them, and they have grown, and are continuing to grow fine healthy plants, but not a single flower is on either. They are, and have been, in a warm room with plenty of light, air, and sun.—R. A.

3935.—Shrubs near a drive.—I have a quantity of *Rhododendrons*, *Laurels*, and *Box* bordering a drive which have been allowed to grow wildly and projecting ten feet. When should I cut them back, and will it prevent the *Rhododendrons* flowering next year if cut hard back this? Can *Syringa* be cut back without harming it? This is for the south-west coast of Scotland.—O. H. W.

3936.—*Marshall Niel Rose* in a greenhouse.—Will "J. C. C." or someone else kindly say what should be the treatment of a *Marshall Niel Rose* in a span-roofed greenhouse? The root is outside, and was planted in the early spring. Since then it has made a number of new shoots, and has now six *Roses* on it. It is syringed night and morning, and liquid manure given once a week.—S. P.

3937.—Treatment of a *Myrtle*.—I bought a *Myrtle* about 2 feet high, but fleggy and thin at the base, so I cut it down this spring and have re-potted it since, and it is doing well. I have put it outside now. Is this the right treatment? I should like to get it to flower next year. Of course, I intend keeping it inside a cool-house during winter. What is the best soil for it?—L. H. B. SCHMIDT.

3938.—Treatment of *Tigridia*.—Do *Tigridia* require any special treatment or soil? I have planted the bulbs both in autumn and spring in the open ground, and have seen them planted in a pot in spring and placed in a cold frame. None of them have succeeded, and I should like to know the reason? No special instructions for treating them are given in the seedman's catalogue.—A. S. M.

3939.—Unhealthy *Cucumber*, &c.—What is the cause of many of my *Cucumbers* going off yellow at the end when about 4 inches to 6 inches long? Are some kinds more disposed to this than others? What is the best sort to grow for market in hot-houses? How can the plants be raised from seed? What kinds of manure are best for the plants? Is it advisable to thin out the fruits besides cutting them when fit? How many fruits may be exposed on each plant?—D. J.

3940.—"Geraniums" for winter flowering.—I believe that "Geraniums" (rooted cuttings) can get to flower in the winter and early spring by taking the cuttings at the right time of year. I have a greenhouse which keeps out the frost, but never is much above 50 degs. temperature in the winter. I shall be very much obliged if anyone will tell me at what times I ought to take cuttings, so as to have small plants in bloom in January, February, March, and April.—CHAMBER.

3941.—Caterpillars in a shrubbery.—I have some trees in my shrubbery that are a mass of caterpillars and web. Will anyone kindly let me know how to destroy the caterpillars, so they look so ugly? They are in little lumps rolled up in the web, and don't seem to care about any other tree but this special sort—some people call it *Pegwood*. Is this the right name? It grows about 10 feet or 12 feet high, bears a few red little berries (four together in little lumps) in winter.—ENGLAND.

3942.—Treatment of a *Cherry tree*.—Will someone kindly tell me what will be best to do with a *Cherry tree* that has been planted six years on a house wall facing due east? It is in very good health, and makes due shoots every year, but never brings any fruits to perfection. Trees, as soon as turned, all drop off. Soil rather light. I should mention that the garden is enclosed by three low walls, independent of house wall about 5 feet from house, and a great many young plants spring up each year. I shall be very glad of advice.—M. A.

3943.—*Marshall Niel Rose* in a vinery.—Lut Neville on twelfth night I planted a *Marshall Niel Rose* on the back wall of my vinery. I keep just enough fire-heat during winter to exclude frost. In the spring following it made three long shoots, which ran to the top of the house. I cut at the top of these in the autumn. This spring these three shoots made other growth, which I expected would have flowered, but they did not show signs of a bloom at all. Should I cut back these young shoots, or should I train them in?—YOUNG GARDENER.

3944.—Grubs and green crops.—Will someone kindly reply to the following?—All my Cauliflowers, Savoys, Brussels Sprouts, Cabbages, Onions, Turnips, &c. are attacked with grubs. They are most destructive, killing all the plants. I find them thirty to fifty grubs at a plant. I try and, the garden has been well limed this winter, and is of fair quality. I have also watered the plants at the roots with soot and lime-water, but it seems to have had no effect on this destructive pest. Which is the best way to get rid of them?—H. C. CHISHIRE.

3945.—*Roses*, &c. in a greenhouse.—I have a greenhouse (about 7 feet square), in which I have a few miscellaneous plants and the following *Rose*—viz., *Star of Waltham*, *La France*, and *Grace Darling* in pots. 1. I want to grow a few more, which would be the best sort in the space given? 2. Would a *Gloire de Dijon*, *William III.*, *Chieftain*, or some other climbing *Rose* do better? I want a *Rose* or *Roses* to give a succession of blooms for half a year only. 3. If grown in pots, when would be the best time to pot them, in what size of pot, and how often should they be re-potted? 4. In re-potting should the soil be chosen from the pot, or only put in the next size larger pot? 5. Is yellow loam essential to grow

Roses well? 6, Would it injure Roses to winter them in a cold frame and then bring them on in succession, and which would be the best to bring in first, and when? Also would it be best to prune in autumn or spring? Locality: A manufacturing town a few miles north of Manchester, exposed to north and east winds.—L.A.S. to KNOW.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

3074.—**Sycamore-leaf (Quercus).**—The red excrecence are caused by a little insect which has punctured the leaf, and all the leaves which appear to have been so unaccounted should be collected and burned.—J. J.

3077.—**Selaginella lepidophylla (Arabis)** is the correct name of the specimen sent, but its more popular name is "The Rose of Jericho," and again it is also known by the name of "The Resurrection-plant." This species of Selaginella may be bought living from any nurseryman.—J. J.

3078.—**Cattleya Mosses (J. Alder).**—The flowers sent are of very inferior quality, and my opinion of them is simply that they are not worth the space they occupy. I can not how large the plants are, nor the number of flowers they carry; it only serves to aggravate their worthlessness.—M. B.

3079.—**Aeride Lindleyanum (A. Galt).**—The specimen you send I recognize at once as this plant, and I have received a quantity from the Madras Presidency from time to time, where it appears to grow in abundance. It is more robust in growth, and the spikes are always branched, as you say yours are.—M. B.

3080.—**Madeoivallia (F. W. Vere).**—I am unable to express any opinion as to your flowers, as when I got them they were past recognition, but as you say you have M. Harryana with thirty-four flowers open, I should suppose you have quite a grand lot of these plants; they cannot be equalled for brilliancy of colouring.—M. B.

3081.—**Acanthophippium bicolor (Eumophry Clunker).**—This is the name of the second Orchid you send. These plants cannot be called showy Orchids; the flowers, however, are of good size, and to me they are most interesting. I used to grow this and several other kinds some few years ago, and they were of as much value to me as any other kinds.—M. B.

3082.—**Aplidystum Findlaysonianum (G. Taylor).**—This is the name of your No. 2. From the Malay Peninsula. It has the veins netted towards the margin, and it would appear to come in with *Hemidystium*; but in the present plant the veins are very obscure, and I quite agree with the late J. Smith in establishing this genus for it, which he did in 1854.—J. J.

3083.—**Neotipteris Grevillea (G. Taylor).**—The frond you sent for name appears to me to be of this species. I recognize it particularly in winged alder. You said you got it from Burnham. There are many fine Ferns in that country which would well repay the cost of introduction. It has been returned, as requested, but upon another occasion please enclose stamp for postage.—J. J.

3084.—**Grubs and Carnations (Miss Forster).**—The so-called grubs are one of the Snake Millipedes, the spotted Snake Millipede (*Julus guttatus*). They are very annoying pests, and are very difficult to get rid of. When beneath the soil it is almost impossible to make most insecticides reach them in sufficient strength to injure them, but strong salt and water is said to be effective. Trapping them by burying small slices of Mangolds, Turnips, or Potatoes near the plants so inch or so below the surface is very useful. Pieces of cotton-wool also form good traps. A small wooden skewer should be stuck into each trap to show where it is. Laylog small pieces of slate or tile about is also useful, as the Millipedes creep under each thing for shelter.—G. S. B.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of Gardening Illustrated, 37, Southampton-street, Strand, London, W.C.

Names of plants.—D. K. F.—Send better specimen.—F. W. Dwyer.—Specimen too much dried up to name. Pines send a better one.—Mrs. M. Banks.—Insufficient specimen.—Hay.—Wo do not, as a rule, name them, but the one sent is no doubt W. A. Richardson.—Denby Court, Harrogate.—Clytus Adami.—Mrs. Burne.—*Justicia carnea*.—J. A. Espinasson.—Probably *Calceolaria violacea*, but much dried up.—*Misc. Utricularia*.—*Elaeagnus variegata*.—J. J. C.—The Rose had all been to pieces.—E. C. G.—The numbers of specimens all detached, and you do not give your name and address.—J. J. Hant.—Specimens quite rotten from being soaked wet, so cannot name.—C. F. Sharp.—We should say that it is *Schmrock*, certainly.—Iera.—So-called Lily *Fritillaria Kamehobata*. Other specimens too much dried up to name.—A. H.—Your Orchid flowers came to hand in a very bad state, some with numbers and some with none.—Amongst them I recognize *Epistedium vitellium*, *Odontoglossum alabastrum*, *Demodromium amoumum*, an *Oncidium* which looks like *supplantum*, *Brassia caudata*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Winford.—Punneta Apply to Messrs. Draper, gardeners, Centre Avenue, Covent-garden market, London, W.C.—**Arin.**—"Dictionary of Gardening," by W. Nicholson, published by L. Upcott Gill & Co., Strand, London.—**Aderson.**—Wo do not remember having received any flowers from you.—J. N. S.—"Vills Gardening," E. Hobday, Macmillan & Co., London.—**Mildred.**—The best plan will be to write to the people from whom you bought the material.—F. S.—We do not know the plant you name, but if you will send a portion of it (in flower, if possible) we will tell you its name and how to treat it.

F. Fane.—It is not unusual for Foxgloves to sport as the specimen sent has done.—*Louisa Dennis.*—Apply to Mr. W. Paul, Waltham Cross, Herts.—*Mrs. Jackson.*—Apply to Messrs. G. Bonyard & Co., Maidstone, Kent.—*Charley Davice.*—Most likely the Vines were weakened with the petroleum dressing. It is a very dangerous thing to use on Vines. Send more particulars, please.—*M. J. Mactaggart.*—We do not think that *Fritumia ohonocia* is an objectionable plant to have in a window garden.—*A. W. E. Weston.*—Please say what plants you wish to use the soil for, and then we will endeavour to advise you.—*Zonic.*—The Kals is correctly named as "Euda."

BEEES.

SEASONABLE NOTES.

COMB being very valuable to the Bee-keeper on account of the quantity of honey consumed by the Bees in the elaboration of the wax, it should not be taken from the hive, except in the case of section honey. The honey extractor leaves the combs uninjured, so that they can be returned to the hive to be refilled by the Bees, and not only are the combs preserved and more honey obtained by extracting, but more room is thereby given the Bees for brood rearing. By extracting the Bee-keeper is also able to secure honey even in a poor season, when little or no section honey is to be obtained, and, if it be wished to work for honey instead of increase of colonies, swarming can be avoided by the use of the extractor; but honey should be extracted from store combs only, not from any combs that may contain brood.

EXTRACTED HONEY.—In working for extracted honey, the method called doubling is sometimes practised. Two strong colonies are selected, and from one of them all the brood combs are taken, and the Bees brushed back into the hive. The combs are placed in an empty hive, which is put on the top of the other stock so as to form a second story. By this means a double set of combs is given, and the hives are soon full of Bees, the hatching taking place above and below. As the brood hatches out in the upper story, the cells become filled with honey, and as fast as filled the combs are placed in the extractor, emptied of their contents, and returned to the hive to be refilled, the brood being then reared in the lower hive only. The hive from which the brood combs are taken is filled up with bars of comb foundation. As the Bees collect honey they put a little in each cell, so as to expose a large surface to the influence of the heat of the hive, and during the night, if warm, the moisture has evaporated sufficiently, to enable the Bees to carry the honey to the upper cells, where it is permanently stored, but if more honey has been collected through the day than can be evaporated during the night, and all the cells are in use, the Bees returning the next day with stores have nowhere to put it; they, therefore, convert it into wax, which they add to the cells, and make preparation for swarming; removing surplus honey from the hive by means of the extractor will, therefore, frequently be the means of preventing swarms leaving, while the Bees will be stimulated to greater activity to refill the empty combs. In the ordinary way, the heat of the hive assists in evaporating the superfluous moisture, and when the process of evaporation is completed the cells are sealed over.

INTRODUCTION OF QUEENS.—A frame of comb containing brood and eggs introduced into a queenless hive is one way by which a colony can be saved, as the Bees will immediately begin to fashion royal cells round some of the worker grubs or eggs, and rear queens from them; but the best way of setting up a queenless colony is by giving it a fertile queen. In order to introduce a queen successfully it is necessary to use a queen cage in which to confine the queen when first placed in the hive, otherwise the Bees are liable to destroy her. The cage containing the queen is pressed into a central comb as far as the base of the cells, if what is called a pipe-cover cage be used, great care being exercised not to injure the queen. The comb selected should be one containing honey, that she may be supplied with food; the Bees are now sprinkled with syrup, and the hive closed till the next day, when the Bees are again sprinkled with syrup and the queen released from the cage, and watched to ascertain if the Bees take to her. Should they seize her by the wings and treat her somewhat roughly, she is released from the cage and the experiment tried the next

day. If it is wished to exchange an old queen for a young one, the old queen is searched for and removed, placed in a cage and introduced between two of the combs for about six hours, then removed and the young queen placed in the cage, and in two days released, when she is, as a rule, favourably received by the Bees. In the case of a hive having been queenless for some time the introduced queen may be caged for three days. There are several kinds of queen cages; a very good one is made of wire net and formed to fit between two combs, having a flange on the top to prevent its entering the hive too far, and can be inserted through a hole in the quilt. It has an entrance on the top in which to insert the queen, and by pressing down a wire, a door is opened at the bottom which allows the queen to escape into the hive. Difficulty is sometimes experienced in introducing queens into hives which contain no young Bees, the old Bees being liable to encase and destroy the new queen; it is, therefore, advisable to insert, if possible, some frames of hatching brood on which to rear the new queen.

S. S. G., Parkstone.

POULTRY & RABBITS.

3875.—**Fowls losing their feathers.**—There can, I think, be no doubt that the quierist's fowls are troubled with the vice of feather eating. It is, of course, possible that insect pests are at work, and they may both destroy the plumage themselves, and also by the irritation caused by their movements over the skin of the fowls cause the latter to pluck the feathers in their search for their enemies. I do not, however, think that insect vermin are often so plentiful as to cause the feathers to fall off, particularly round the thighs, as in the case mentioned by "Belle Cherie," and so we must fall back upon the first solution of the mystery. It may be asked why feather-eating should develop itself to such an extent in the quierist's run, where the birds are seemingly well cared for, and yet no trace of the habit should have been apparent when the birds were purchased. The explanation, I feel sure, is not a difficult one. I have no doubt the fowls were formerly provided with a free range. Here they could be constantly on the move, and be moving to fresh sights and sounds all the time. They would thus get no opportunity for standing still moping. In a confined run the case is altogether different. The fowls have not the opportunity for much running about or something to divert themselves, and so it comes to pass that feather-eating is resorted to, and if not checked at once is soon carried on to such an extent as to become a very bad nuisance. As to a cure, I am afraid it is impossible to name one when the fowls have become thoroughly addicted to the habit; but it is possible to check the vice a little. This is done by paring the edges of the upper portion of the beak of the fowl, which prevents it taking a firm hold of the feather. The trimming does not make the bird unsightly, nor is the operation attended with any pain, and it undoubtedly puts a stop for a time to the plucking; but, like our nails, the horn of the beak soon grows again, and the operation must be repeated. Some good may be done by giving the birds occupation of some kind. Corn may be thrown down in the runs and covered with soil for them to scratch over; Cabbages may be suspended from the sides of the run, and an occasional ramble may be permitted. I believe the habit is found more frequently in some breeds than in others, and I also am of opinion that a single bird will soon contaminate a whole flock. Not only is feather-eating objectionable because it disfigures the fowls, but it makes them more susceptible to cold.—**DOULTING.**

How to hold a fowl.—Few persons know how to secure a fowl properly. Never seize a fowl by the tail, if a fine bird, nor touch the back, but grasp both legs at once with a firm, tight, quick hold, and then raise free from the ground or perch and hang the body down clear of any obstacle. This method does not ruffle the plumage or turn a feather, which in a fine bird cannot be avoided. When the web of the feet is once broken it can never be united again, and where much handled this often occurs, giving the bird a ragged appearance.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

WATERING THE PLANTS.—I fear this is a detail of culture not well understood by the ordinary amateur cultivator. They either give too much or too little or at the wrong time. Although Chrysanthemums are moisture-loving subjects, it is a mistake to suppose they cannot have too much. Never ought the plants to be watered without the attendant is positive of their condition. Every plant ought to be tested for supplying it with water. There is no better method of doing this than by rapping the pot with the knuckles. If the soil is dry the pot has a peculiar light ring, if wet a dull, heavy one. If found in the former state water should be given in sufficient quantity to thoroughly wet every particle. If in the latter state wait until the soil approaches dryness. To give a small quantity because the soil is moist, or not dry enough to receive a full watering, is a practice that should be condemned, because it is misleading for future test. While the soil on the surfacing is moist enough, that in the middle and near the bottom is quite dry. The dripping system is bad in every respect and should be rigorously avoided. Although water may be applied in a methodical manner, another source of injury to the plants may exist. I allude to the employment of water in an unfit state. That coming direct from wells, tanks, or water-companies' pipes is not in a fit state to be given to plants without first having been made warm by exposure to the sun and air for at least twenty-four hours. If doubt that quantity of time could be allowed so much the better. Water used in such a cold state must cause a check to the roots, and thus to the even progress of the plants, which cannot fail to be injurious. Cultivators who have not the command of rain-water are also heavily handicapped as compared to those who have an unlimited supply. Water that is impregnated with lime, as that coming direct from chalk wells, is injurious. Even though Chrysanthemums may be calcareous-loving subjects they can have too much of it. Plants supplied with water of this character generally have pale-coloured foliage; at least, where no amelioration of its natural tendency to lime is practicable. It comes within the possibility of everyone to soften the water, where thus hard, by artificial means, so readily can this be done now by the aid of Anti-calcaire, commonly called milk of lime, or even common washing soda will effect the purpose, rendering the water quite soft by precipitating the chalk which is held in suspension to the bottom of the tank or tub. A quarter of a pound of ordinary washing soda is sufficient to soften 40 gallons of water. Dissolve the soda in boiling water, and add it to the bulk named, say, an ordinary petroleum cask full, for instance. In twenty-four hours' time the water will be quite fit for use. Do not disturb that at the bottom, which is so heavily mixed with lime through the precipitation of the chalk, as this would be injurious

to plant life if it came in contact with the roots. If tubs were kept constantly in use according to the quantity required, soft water could always be had for the plants. Where a larger quantity of water is required Anti-calcaire gives the least trouble in preparation; 1 lb. will be sufficient for 250 gallons of water. All that is required is to dissolve the powder in the bulk of water by stirring it well, when the chalk will be precipitated to the bottom of the tank, and the water rendered soft. If the tank were fitted with a tap 4 inches from the bottom the softened water could be run off into other vessels without fear of disturbing the objectionable sediment at the bottom of the tank. Another tenkful of water could be prepared also while the former one was being used, thus keeping up a constant supply of softened water. Even if lime in excess be added to chalk-water, the water becomes turbid, and the carbonate of lime, formerly held in solution, is precipitated, rendering the whole soft. In this way ordinary quicklime is valuable as a softening agent. E. M.

3047.—Chrysanthemum seedlings.—If the plants are still in the seed-pan lose no time in placing them in 3½-inch pots in a compost of two parts loam and one part horse-manure, with sufficient coarse sand to keep the whole porous. A cold frame stood in a sunny position affords the best site for the plants for a time, until they are firmly established. A bed of coal-ashes will keep the pots cool and prevent the ingress of worms. Water carefully with tepid water, and give no more than is required to keep the soil moist. Admit air freely to induce a stocky growth. Place alongside of each plant a stake, to this secure the single stem to prevent its being broken. When the plant reaches 1 foot high most likely other shoots will push from the main stem. With a view of thoroughly testing each plant, retain five of the side growths of each as well as the leading shoot, allowing one bloom to develop on each. By encouraging these side shoots as well as the leader, a better opportunity is provided of testing not only the form but the colour of the flower; seldom does the leader and the side shoots produce exactly similar blooms. From the pots named the plants should be shifted into those 7 inches in diameter; in these they will flower. A position in the open where they will obtain abundance of sun and air, but be sheltered from north and south-westerly winds, will be the most suitable after they receive their final shift. After a hot day syringe the foliage thoroughly well over in the evening, and keep the leaves free from insect pests. When the pots in which the plants are to flower are full of roots, weak liquid-manure given twice a week will prove advantageous.—E. M.

The seed has not been sown early enough to obtain strong flowering plants for this year; it should have been sown in heat in January or February, and the plants would have been now half-a-yard in height, and would flower with the named varieties in November. The plants now about an inch high should be potted on in larger flower-pots, and some of them may yet chance to flower. At this time of the

year all the flowering plants are out-of-doors, where they make a cleaner, healthier growth than they do under glass; but small plants an inch high should be grown in frames until they are 6 inches or 9 inches high.—J. D. E.

FERNS.

3044.—Ferns and out-flowers.—Except the Adiantum, few Ferns are of much use for cutting. Pteris serrulata and P. cretica are useful to some extent, and I used to grow Nephrolepis exaltata for this purpose also. The most useful by far of all Ferns (perhaps excepting Adiantum cuneatum) for cutting and decorative purposes is the Black Maiden-hair Spleenwort (Asplenium Adiantum-nigrum), a hardy British species. This is precisely the same thing as the so-called French Fern, of which such immense quantities are annually sold in the flower-markets and shops. It grows freely in any light sandy soil (peat or loam), and I should think would be worth cultivating on a large scale in this country. There are parts of Surrey where one could almost cut this Fern with a scythe; at least, such was the case a few years ago. A third invaluable plant is the elegant and lasting Asparagus plumosus, which thrives in any warm greenhouse.—B. C. R.

There are few Ferns better adapted to mix with cut flowers than the old and well-known Adiantum cuneatum, but the fronds do not last long in a cut state. An excellent substitute now much used is the Asparagus "Fern," as it is termed. Of course, it is not a Fern at all, but an exotic species of Asparagus—botanically, A. plumosus nana. Adiantum formosum is an excellent species for cutting; the fronds last longer out than any other Adiantum I know. I also use a quantity of Davallia Mooreana, a handsome species, the fronds of which last a long time in a cut state.—J. D. E.

When you except the Maiden-hair (Adiantum) you dispose of some of the best kinds for cutting, as their elegant character fits them well for association with flowers. The Asparagus plumosus lasts well when cut and is very charming, its feathery character being most marked. You must get good specimens of the plants if you wish to cut much from them, and nothing is better than Adiantum cuneatum, which is sold largely. I know one unscrupulous man who has two large houses filled with nothing else, all for cutting, and the plants are grown cool, not in too much heat, which makes the fronds more tender. Pteris serrulata is a good Fern for cutting, and the fronds stand well, but they are not so graceful as those of the Adiantum, whilst mention may be also made of such pretty things as Pteris Mayi, the fronds quite silvery, but you must place chief reliance upon the old Adiantum cuneatum, which is quite the best Fern to supply fronds for cutting.—C. T.

Several of the Pterides are very useful for cutting, notably cretica and serrulata. Oxychilus japonicum and Phlebodium aureum also keep well, though the fronds of the last named are too large for small vases. What are called the Asparagus Ferns are very useful for cutting, and will be more useful than the plants are more common,

GARDEN WORK.

Conservatory.

Specimen Heaths now in flower should occupy a light, open position. With careful management, Erica, Davallia, and the varieties of variegated may be kept in the conservatory as long as their flowers keep in condition without injury. After flowering, pick off all seed-pods, or leaving them on only a short time has a very exhausting effect. The same course should be pursued with Acaules and all hard-wooded plants. Epacris will now be growing freely, and as soon as growth is completed, move to a cool, airy house or pit, and to July place outside in some sheltered position to complete the ripening. I must hardly say that all plants placed in the open air must stand either on coal-ash bed, or some impervious material where worms cannot work into the pots. The early-flowering Azaleas may soon be placed outside, and if the plants have not been reported, clear, weak liquid-manure will assist greatly in plumping up the buds. Abutilons in pots, which have been flowering some time, may be pruned hard back, and the cuttings put in to make young shoots. The shoots which break away from the pruned plants will produce flowers in autumn. Set the plants outside; they will come early enough. I have planted them out and lifted them again in autumn. They do very well so treated, but the lifting must be carefully done not later than the first week in September, and the plants must stand outside in the shade for some time to get established in the pots before housing them. Keep Kalanchoes in a light position. The tops which are removed from young-growing plants will make good cuttings, that will soon strike. Continue the shifting of Chrysanthemums into their blooming pots, which should not be less than 9 inches in diameter, using rich, rough, tarty soil, leaving room in the pots for a top-dressing later on. Do not be tempted to use stimulants of any kind till the pots are well filled with roots. The soil, if of the right quality, will furnish sufficient food for growth till the buds are forming. Late Chrysanthemums are so much thought of now as early autumn ones. And young plants are out down now and lifted into 5-inch pots when the growth starts, they will be time enough for winter blooming for cutting, or to furnish plants for the rooms with suitable sized plants. Salvia of several kinds are useful for winter flowering. These may either be grown on in pots or be potted out. Larger plants are obtained by the planting-out system, and Salvia will soon get established after lifting, if the latter process is not delayed till too late. Give them room enough for full development. Many of these of the hardier winter-flowering plants may be planted out with advantage. This is by far the best way of treating Eupatoriums, and if this is followed for a few years, the plants being pruned back after flowering, immense bushes may be obtained that will continue in flower a long time. Saw another frame of Cinerarias for blooming in spring, and those plants which have been set in a cool, shady place may be divided, and the suckers potted off as soon as the latter can be safely taken off. Pot off Primulas, both the Chinese and also the obsolete varieties. Pot out Arum lilies as soon as there are any signs of growth. These are sometimes planted in trenches, but where many plants are grown the trench system involves more labour, and takes up more space.

Stove.

Winter-flowering stuf will require shifting on now, and if a small, low house or pit can be secured, move in there after repotting, and keep close for a time, applying no thin shade when the sun is bright. I am not in favour of permanent shading, though I am obliged to use it more or less. We never have too much light for plant growing in this country when the sun is not actually shining. Perhaps a few of the largest plants in this house may be moved to the conservatory, and this will give a welcome relief. See that all the plants under glass are free from insects. If there should be any, the best way is to use weather any falling off in atmospheric humidity, red-spider and thrips will soon make their appearance. The latter choky attacks had-leaved plants, such as Crotons, India rubbers, Marantas, and things of that type. Fungating with Tobacco an successive evenings will destroy them; but it would be necessary to follow it up till the insects are all destroyed. Sponging with soft-soap and water will do very well, but it takes up more time than fumigating. Use the shade only when it cannot be dispensed with. Such plants as Crotons, Dracenas, &c. will not lay in colour if too much shaded. Pot off cuttings of Bourardias. These will do best in a warm, loose frame till established. Older plants of Bourardias will now be under cool treatment. Many people are bethered to get good loam for plant growing. I never could do much with loam from a limestone soil; it is generally too poor and hungry. Many things will grow in Wimbledon loam that would be miserable things in inferior loam. If such loam as afore-said must be used, mix with it a larger proportion of peat and leaf-mould or mid manure than the customary in using the better class loams. There is a great deal in getting the right kind of soil for plant growing. Succose hinges upon it. Stove Palms may be repotted, if necessary, though, in a general way, the difficulty is to keep the plant small enough.

Ferns.

These should now be in good condition; but Ferns can never be seen at their best if crowded together. Each plant requires room for the full development of its fronds, and one really well-grown plant is worth half-a-dozen stunted and stunted things. But though we may talk and write about the desirableness of plenty of room, how few of us can give it where anything is doing. Ferns are now in new species and varieties are fair, Jacod, and old ferns are retained until at least it blooms—a question of building new houses to hold the stock. Well, glass is cheap enough, and Ferns are exceedingly attractive at all seasons, and where one has plenty of room it is easy to brighten up with a few foliage plants, such as Crotons, Dracenas, Marantas, &c. The fine-leaved Begonias too, associate well with Ferns. Continue to pot on young

plants for specimens, and if more room cannot be afforded, throw out the old plants. There comes a time when even old Ferns are on the decline, and will not pay for keeping, and I never recommend an old plant, except of a very scarce kind, to be broken up for propagating purposes.

Melons in Frames.

This is splendid weather for Melons on manure-beds. One can feed advancing crops without any fear of canker, and bottom-heat can be maintained without a continual renewal of the linings. Ventilate freely during these hot days. I generally draw the lights up before inserting the props, so that a chink of air can be given at the bottom of the light. Where there is a gentle circulation the leaves will not scorch so long as the roots are in a moist condition. Keep the growth thin, but never out of an old leaf after the crop is set and swelling. Melons do not make much growth, and if they should it make its appearance, should be cut away. Give a chink of air early in the morning to purify the atmosphere in the frame from the accumulation of the night.

Window Gardening.

Where well-filled, window-boxes will now be in good condition, and will utilize profitably weak stimulants once a week or so. Remove dead flowers and leaves frequently. Plants on balconies must have regular attention in watering. Climbing growth round window-boxes and on trellis-work should be regularly trained. Room plants now are composed chiefly of foliage plants. When there are plenty of flowers outside, a graceful Palm or a delicate-tinted Fern finds more favour as a room plant. Cooco Weddelliana is a graceful Palm for a small vase on the drawing-room table, and though considered so a stove plant, I have known it wintered in good condition in a sitting-room. Careful management will do much in plant culture.

Outdoor Garden.

This has been the most trying season I remember for newly-planted evergreen trees and shrubs, and many deaths have occurred, especially where the watering has been intermittent, and not of a thorough character. The value of mulching is great, and more than one valuable specimen has been saved by the use of the garden-engine or syringe over the foliage in the evening. When the rain comes in a shower, it is a relief, but all things will save life, although I do not look upon the use of the syringe over the foliage after a hot, drying day as a small matter. It is like the bath to the weary traveller after a day's journey through a hot, dusty country. It will be a difficult matter to grow good Peaches in the south during a season like the present. The beds must be mulched with old cow-manure, and if the precaution was taken to bury some old cow-dung in the soil things might be so bad as to be a failure. It is a curious thing, that through different gardens and notes the flowering of hardy plants. In poor ground, where the plants are crowded, and have had no manure, and the borders but little preparation before planting, there is not much success to chronicle; but in good land, well manured and deeply worked, things are doing well, though the development may be rather less than usual. Recently-planted Ferns and alpine plants will require water, and in some cases a little Coccolite will be useful. The same kind of mulch will save watering of flower-beds in a dry spot. Straggling plants must be pegged down soon after planting, before the growth gets firm. Tenulewms may be sown now, where there is a good supply of water. The turf, if kept moist, can get established at this season.

Fruit Garden.

Condense layering Strawberry runners for forcing. Let the main reliance be placed on the best old sorts with a reputation for size and quality. Nowadays there must be size. Vicomtesse Hericard de Thury is too small for some. This variety is otherwise a splendid forer (none better), and good sized fruits may be had by severe thinning, which is a necessity in fruit growing. It was fully recognized in the past by leading men, and nothing has required to prove that even by the use of artificial stimulants can a tree be enabled to carry more than a reasonable amount of fruit. The application of stimulants requires judgment. This has often been carried too far in the case of Grapes, and the large, gouty berries, the outcome of a too stimulating diet, have worn a foxy appearance in consequence. What is termed fish in Grapes (colour and bloom) cannot be obtained by excessive feeding at the same time. More can and will be done in the use of stimulants in the future than has been attempted in the past. Many men are experimenting, and something definite will grow out of it. Stone fruits on walls may be gone over, and the breast-wood shortened to three or four leaves, and the young shoots retained for extension laid in. The young wood of Peaches is easily damaged by the wind if not secured in good time to the wall. Some effort should be made to clear Plum-trees from insects. When there are to be done on a large scale expense has to be considered. It is a question if anything is obtained, it is cheap, a self-soap, with a dash of Tobacco powder or paraffin in it, and the trees sprayed with the mixture. Quassia is a very good insecticide, and moderate in price. Peaches under glass, from which fruit has been gathered, must be syringed freely, and water given when required.

Vegetable Garden.

Tomatoes outside, where mulched, and the roots kept moist and cool, are growing freely. Surplus growth must be removed when the finger and thumb can do all the work. Under glass the fruits are colouring up well. It is a common practice to cut the fruits as soon as they begin to colour, and ripen them in the sun; but it is better to let them ripen on the plants—at least, so far as regards the flavour and condition, though gathering the fruit before it is ripe saves the plants. This is just the weather for Cucumbers, where well cared for, either in houses or frames. Plenty of moisture, and to do all the spheres and at the foot a little stimulant to be added to the water for the beds, frequent top-dressings of rich soil, constant stepping of the young shoots, and no fruit left to get old, with a thin shade in bright weather, and just a little artificial heat at night till the nights get warm enough to maintain a temperature inside the Cucumber-house to something over 60 degs. It is a very trying time for vegetables, especially in the eastern counties where the rainfall has been so light. Yet where the land has been

done well the crops are looking well. Potatoes are growing freely, dry though it is, and are all now, except those planted very late, earthed up. This earthing up keeps the roots cool, and if we should get a wet autumn it will facilitate the escape of the water. The question is, is it a good idea to give the ridges a pronounced slope. The green-crops are suffering. A Cabbage or a Cauliflower spreads out a large surface of leafage, which on a dry, hot day will evaporate a great deal of water, and when scarcely any rain falls for months, Cabbages and Cauliflowers must be poor in size and quality if left to themselves; but if mulched and occasionally soaked with water they will enjoy the sunshine. The question arises—Can we flood the Cabbage-bed? It can be done, of course, if we do not mind the expense. E. HORDAY.

Work in the Town Garden.

Watering is a terrible business now, and in many places the difficulty is to get enough of the precious fluid. Day after day passes and no rain comes, although it threatens frequently, but we only get a few drops, and then it all passes away and the hot sun and wind together drink up the moisture faster than it can be supplied. In any case, watering by dribsles is worse than useless. Give a thorough soaking or none at all; mere surface sprinklings only excite the plants and their roots, only to disappoint the latter. Newly set out bedding plants, especially if small, must be kept close to the roots, at least until they are thoroughly established in the ground. The Tuberosa-rooted Begonias especially are very exacting in this respect, and in a dry time like this small plants from boxes will not move or make a leaf unless abundantly supplied with water. Verbenas are apt to suffer from extreme drought also, especially a B. Biet, and if kept short of water the foliage often becomes infested with aphids, and Dahlias also must be liberally watered during the early stages. Chrysanthemums ought now to be placed in the beds of pot in which they are to flower, those 84 inches to 9 inches or 10 inches across (inside the rim) being the best size for plants grown in the ordinary way with three or four stems apiece. When growing for exhibition, or to obtain flowers of the largest size for any purpose, the last shift ought to be given not later than the middle of June, but for ordinary decorative purposes, or supplying out-flowers, any time up to the end of the month will do. Of course, after potting less water than usual must be given for a time, but do not let the plants dry or wilt badly. Plants that have been out down to reduce the ultimate height must not be repotted until the young growths are 2 inches long; if these are numerous, thin them down to three, five, or seven per plant, according to the size of pot and number of flowers desired. Tomatoes under glass are setting and ripening their fruit well, but require plenty of water and nourishment, particularly when carrying a far too heavy crop; if started in any way the upper branches will drop their flowers instead of setting them. In such weather as this it is advisable to syringe the plants lightly overhead once a day—certainly when they are growing in a light, sunny, and well-ventilated house. Window-boxes must be liberally supplied with water, though where small plants have only recently been put out in a box full of sand soil it will not do to make this very wet until the roots are running freely in it. But the daily overhead is quite indispensable. B. C. K.

THE GOMING WEEK'S WORK.

Extracts from a garden diary from June 17th to June 24th.

Busy thinning late Grapes; shall bring it to a close this week. This is a very tedious work, and one always feels relieved when the scissor can be laid aside for a time. It is always necessary to look over Grapes a second time; there may not be much to do, but a small berry here and there may be taken out and the light places in the bunches opened out a little. But Grapes should never be thinned more than a foot or two from the bunch in a dish. Give a sprinkling of artificial manure and watered it in with the hose. Finished gathering the last of the earliest Peaches, but late's Early, a free-bearing kind, will be ready in a week. It takes a good deal of Peach to exceed 8 oz., but it pays to have them not less than that size, and the thinning must be pretty severe to average that. Planted Melons for late summer crop, shall plant a few for autumn, or possibly take a second crop from some of those plants now starting. This can be done if I get over it topped; though I seldom rely upon this crop, I often get a second crop from the same. It is merely a question of keeping out red-spider. If that little pest gets a footing in the Melon-house or frame there will be no second crop of fruit. Tomatoes, where largely grown, furnish a lot of work now and it must be done promptly; growth running to waste takes a good deal out. I have mulched all the beds in the Tomato-house with stable manure; this has many advantages and saves a deal of labour, and it is economical. Tomatoes will take a good deal of support where the fruits are growing rapidly. Tomatoes will not set very well if dry at the root in hot weather. In dull weather do not water if it can be put off, but during a hot day if the roots are dry the blossoms drop unset. Picked off Chinese Primulas. Shifted Solanums into fruiting pots. A little pinching by-and-by will keep the plants in shape. I want to get the plants a good size as before thinning them out to set their fruit. Cut down the early-flowering Peargonium and put in the cuttings; the old plants will be kept quite dry till they break. Potted Chrysanthemum I am getting through. Planted out more Leeks in shallow, well-manured trenches. Sowed Vetch's Perfection and No Plus Ultra Peas. The bottoms of the trenches were soaked into puddle before the Peas were sown. The Peas under such conditions will germinate immediately. Shifted the earliest struck Potatoes into 5-inch pots; they are growing in a close, warm pit for the present just to stimulate root action, but as soon as that object has been accomplished free ventilation will be given to build up sturdy growth with substantial healthy foliage down to the bottom. Made a last sowing of Cinerarias for spring blooming. The early sown plants will now be ready for 3-inch pots. Sowed Parsley and Early Horn Carrots in south border. Put in cuttings of Pinker under benchlight. Prepared beds of light, sandy

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

soil. Layering Strawberries for forcing is being continued as fast as the time devoted to other work will permit. Sowed Endive; probably a few of the plants may bolt, but shall sow again in ten days, and I want Endive as early as it can be obtained. Planted out a lot of young Pinks which were struck early in heat; they are intended for potting off in autumn for forcing. Planted out Autumn Lilies. Only a few of the stock is planted; a few dozen plants will be grown in pots for early bloom. Made a sowing of Rosette Colewort; these plants will come in useful to fill up vacant plots for winter use. Watered wall and other fruit-trees which are carrying good crops. Turned the hoes on the Raspberry plantation. The ground had previously been mulched with manure. Shifted Cockscombs into flowering pots and returned to hot-bed.

INDOOR PLANTS.

FINE STOVE PLANTS.

ANTHURIUM.

Of these there are several that will bear a favourable comparison in their flowers with the best plants brought into the country in either recent or bygone times. There are some that especially deserve a place in even the most select collection of blooming stove plants; but as they require somewhat different usage as to soil, it

the spring, when they have made a few roots from the base. That these exist before the crowns are separated from the parent plant is essential, as, if taken off before they have formed roots independent of the plant that has produced them, they will be long in growing away freely. When taken off, place them in pots just large enough to permit of the roots being inserted without injury. They are surface-rooters, requiring an abundance of water, consequently they do not need a great depth of soil, but must have plenty of drainage material. Half-fill the pots with crocks. The soil should consist of fibrous peat three parts, to one of flaky rotten dung that has been well dried. Such as has lain exposed on the surface for moulching a Vine-border or an Asparagus-bed is in the best possible condition for the roots of these Anthuriums. Add to these a fifth part of leaf-mould, a good sprinkling of crocks, broken the size of Horse Beans, and a fair quantity of silver sand, mixing the whole well together. Do not, even whilst the plants are small, sift the soil, but pull it to pieces with the hand; press moderately firm, and pot the crowns an inch or so down, just covering the roots a little; put a small stick to each for support, give water, and place them in a brick heat of 65 degs. in the night, with an increase during the day. Keep them a little close until they begin to grow, but not so much confined as would be requisite in the case of ordinary cuttings. Raise the temperature both day and night as the season advances, giving air in the daytime when the weather is such as to require it, and shading slightly when the sun is upon them. When a fair amount of roots have been formed the plants should be moved into pots 2 inches larger, using similar soil to that in which they were before placed. Continue to treat through the summer as already advised, syringing them freely every afternoon, and also giving plenty of water to the roots. Reduce the temperature, and discontinue shading as the weather gets cooler, keeping them through the winter in a temperature of 55 degs. in the night; but do not let the soil get dry. Repot in April, giving 2 inches or 3 inches of a shift, still half-filling the pots with drainage, and using the soil in a more lumpy state as the plants get larger. This season they will push up flowers from all the strongest leaves, but it will not be advisable, even whilst in bloom, to move them out of the stove, as a lower and drier atmosphere would interfere with their growth. Continue the summer and winter treatment in this and subsequent years as already recommended, giving more pot-room when it is wanted. They will go on for years increasing in size as long as required, and, when they get larger than desirable, they may be reduced by division of the crowns. These Anthuriums can be increased from pieces of their rhizome-like stems cut in bits an inch or 2 inches in length, inserted in soil such as that advised for potting the crowns in, and treated similarly afterwards. They can also be grown from seeds managed as hereafter detailed for the propagation of *A. Scherzerianum* and its white variety by this method.

A. SCHERZERIANUM (here figured) is now well known, and is undoubtedly one of the very finest and most distinct flowering plants ever introduced to this country. By judicious treatment in recent years it has been grown to a size, of both leaf and flower, such as was never anticipated from the small examples produced when first bloomed after its introduction. It is from Costa Rica, and can be readily increased from seeds. For a considerable time after it was brought to this country few persons succeeded in sowing it, simply because they did not allow time for the seeds to get matured; they are borne on the outside of the spadix, in compressed globular, pulpy masses about the size, and when ripe of the colour, of pale Red Currants. To produce good seed flowers should be selected that open towards the close of summer; about August, when the spathe decays, they must be cut off, leaving the twisted spadix growing upon the peduncles: These will remain through the winter in much the same condition as they appear in the autumn, quite brown, with little apparent vitality in them, but in the spring the spadix will entirely or partially untwist, and the seed-vessels will begin to swell, being at first of a green colour, afterwards becoming orange-red as they ripen. When fit to gather they are sown in shallow trays, and will part

Part of a fine plant of *Anthurium Scherzerianum*.

3917.—Lilies and Irises for market.—The common White Lily is much grown for market round London, and I believe pays fairly well where the soils suits it, but it is liable to go off wholesale, being attacked with a kind of fungus. The Tiger, the Orange, and some varieties of umbellatum, are also grown to a certain extent. I should not advise the culture of these in heavy soils that retain much moisture in the winter. Iris Germanica and the English and Spanish Irises are grown for market, but the prices for outdoor flowers is low, and only growing them in quantity will pay. By C. B. G.

will be necessary to treat of them separately. Amongst the more recent introductions of Anthurium is the white-spathed *A. candidum*, from the United States of Columbia, a plant of somewhat slender habit, with rather small, erect, ovate, lanceolate leaves, on proportionate foot stalks; the spathe is about 3 1/2 inches in length. It associates well with *A. floribundum*, a new Grenada species, which has much broader, slightly lanceolate leaves, dark-green, and of compact habit: the spathe of this plant are also white, and it lasts long in flower. Both may be increased by division of the crowns taken off in

readily from the spadix. They should then be removed, washed out of the pulp in the way usual with Melon or Cucumber seeds, and set once sown. **Pearse**

LARGE-SIZED SEED-PANS, in which place an inch of drainage; then get some clean Sphagnum Moss, free from Grass or weeds. Chop this quite fine with a pair of scissors or hedge shears, and add to it one-fifth of clean sand and some crocks or charcoal, broken about the size of smelt Pass. Fill up the pans with this mixture, pressing it firmly down, and water the surface, sprinkling a little more sand if that which has been already mixed with the Moss is washed down. Damp the surface again and sow the seeds thickly and evenly over it, pressing them gently down with the hand, but not covering them in the least. Put a prepaeting-glass over the whole to keep in the moisture, as this will prevent the necessity for giving much water; if this is given in considerable quantities it has a tendency to wash the seeds overhand into the material, which must not occur, as they vegetate much the best when on the surface. Keep the whole quite moist; it must never be allowed to become dry, but, when water is given, let it be applied with a fine rose, so as not to disturb the seeds at all. Place in a night temperature of 65 degs., and 10 degs. more in the day; in a few weeks they will begin to grow. Let the

YOUNG PLANTS, from the time they first vegetate, have plenty of light, but do not allow the sun, when at all powerful, to come upon them without shading; give air in the middle of the day, and syringe overhead in the afternoons. By the beginning of September they will be large enough to prick out, several together, into 3-inch pots, half-filled with drainage. Material similar to that in which the seeds were sown should be used. Keep the soil well moistened, for this Anthurium is a swamp plant, and cannot endure to be dry at the roots. Keep through the winter in a temperature of 55 degs. or 60 degs., and a few degrees warmer in the day. This is considerably hotter than is requisite for them when they get larger; but the object now is to push them on without loss of time. About the beginning of March move singly to small pots, in material such as used before, with a little fibrous peat added; through the spring and summer keep at about 60 degs. or 65 degs. by night, with a proportionate rise in the day. Treat as to moisture, light, air, and shade as advised for last summer. By the end of June give 4-inch or 5-inch pots, according to the size they have attained; the soil they now require is one-half the best fibrous peat to about an equal quantity of chopped Sphagnum, with a liberal addition of sand and broken crocks or charcoal, half-filling the pots with drainage. Treat as hitherto recommended up to the end of September, wintering as before. Again pot them in the spring, giving pots 2 inches or 3 inches larger. This summer they may be allowed to open a few flowers. Most of the plants will differ more or less in the size, shape, and depth of colour in the blooms. Remove them before they form seeds, as the progress of the plants will be stopped if they are allowed to do so. Those that have the largest and best formed flowers should be marked, and have special encouragement. As they grow up into a useful decorative size they may be kept at a temperature of 50 degs. in the night during the winter, and should not receive so much water, but still enough to keep them growing. They will make the strongest leaves in the winter; through the spring and summer let the temperature be 10 degs. or 15 degs. higher in the night, and proportionately more in the day. They will go on making larger leaves and flowers until they get five or six years old, as well as forming numbers of crowns, increasing the bulk of the plants for an indefinite time, provided the soil is never allowed to become sour and adhesive—in which case the roots are sure to perish. To avoid this, each year, when repotting, get as much of the old exhausted material away as can be done without injuring the roots. From the time the plants have got to a useful flowering size, the best time to repot is in the summer, after the principal blooming is over; when this is will depend upon the temperature they are kept in during the early spring, as the warmer they are the earlier they throw up the main lot of flowers. Thrips and green-fly are both partial to the leaves and flowers; but the continuous syringing is a general sufficient

to keep them in check, otherwise they may be killed by fumigation. Brown scale thrives upon the leaves, and must be kept under by sponging; so may mealy-bug, should they become affected with it. The

WHITE FORM of *A. Scharzianum* requires treating in every way like the red variety. Both can be increased by division of the crowns, and by pieces of the rhizome in the manner described for *A. candidum* and *A. floribundum*. *A. Andreanum*: This is a most beautiful species, quite distinct from all others. The spathe is large, heart-shaped, corrugated on the surface like the cartilage of the human ear, bright scarlet in colour, and shining as if newly varnished. The lower portion of the spadix is white, towards the extremity yellow; it droops in front of the spathe, and by the contrast in colour seems to intensify the brightness of the latter. It is one of the most remarkable and beautiful plants that has appeared in recent years. It will require keeping somewhat warmer than *A. Scharzianum*. From Colombia. *A. oreatum* has medium-sized leaves. The spathe is 6 inches long, white in colour; spadix purple. A native of Venezuela. *A. Scharzianum* *Wardi* is a very distinct and desirable form of the red species, with immensely broad spathe, which are bright scarlet in colour. B.

3934.—Treatment of Indian Azaleas.—The very probable reason why the plants are not flowering is owing to their not having sufficient light and air in the room of a dwelling-house. The only chance to get them to flower next year will be to place both plants in a light position out-of-doors when they have made their young growth. Keep the plants well watered, and the leaves free from red-spider. The buds will set well in the open air, and they should have as much air as possible after being taken indoors. The Indian Azalea is not at all a good window-plant. Now is the time for the plants to make their growth, and those who have the means should place them in a hot-house, and keep up a minimum temperature of 60 degs. to 65 degs. at night, shade from hot sunshins, and syringe them well twice a day. This will keep the leaves free from thrip and red-spider; both parasites are very fond of the leaves. A surface dressing of powdered bones is excellent to give colour to the leaves. They also require a plentiful supply of water at the roots when in full growth.—J. D. E.

3370.—“Geranium” for winter flowering.—Do not deceive yourself. To bloom Zonal Pelargoniums successfully in winter a temperature of 60 degs. is a necessity, liquid-manure twice a week, each plant in a well-drained 6-inch pot standing upon an inverted pot, with plenty of spears round each plant for air and light, careful attention to watering without overdoing it. All these are necessary to success, and I have proved (by repeated attempts in past years) that it is useless, no matter when the cuttings are started, to hope for bloom in the dull, cold days of mid-winter, unless a summer temperature can be artificially provided. Do not waste time in attempting it.—A. G. BUTLER.

3960.—Malmeson Carnations.—Plants that are always covered with green-fly, whether Carnations or anything else, as you say yours are, are not likely to be satisfactory. Cannot you adopt one of the many simple remedies so often recommended in GARDENING for destroying the flies? Your plants are evidently in a poor way. They are badly nourished, and from the information you send I should say they get too much water. A cool, light vinery is a very good place to keep this Carnation through the winter.—J. C. C.

—If the plants are always covered with green-fly it will be quite a struggle with them to exist at all, let alone carry flowers of good quality. All the varieties of *Souvenir de la Malmeson* and seedlings from it have a tendency at times to produce green knobs in the middle of the flower. I had at least ten per cent. of my flowers like that this year. I pulled the faded petals from one and exposed five of those knobs, like so many flower-buds; but it is a mere freak of nature, and may not occur again on the same plant. A vinery in the winter should not be too hot for them, if the Vines are at rest. It is about the right place. Put them near the roof-

glass, and if green-fly appears, and it is not convenient to fumigate, dip the plants in a solution of 2 oz. of soft-soap to a gallon of water.—J. D. E.

3933.—Flowering plants for a conservatory.—Fuchsias trained up pillars, if there are any, are graceful free-flowering subjects. Camellias are useful for the winter, and as there would be but little syringing them while they are in flower, they would be suitable. The syringing during the spring and summer would be beneficial to the growth of the Camellias. Chorozeamas are useful conservatory subjects, as are *Daturas*, double and single. Acacias in variety are showy. For suspending from the rafters *Bignonia Cherere* and *Tecoma Van Volxemi* are graceful and free-flowering. If room can be found *Maudevilla euecoleus* is worthy a place.—S. P.

—Amongst Palma and such things you would not get permanent flowers—that is, of the ordinary conservatory type; but if the house is very lofty and provided with abundance of heat, you could grow such things as the *Brownias*; but they require heat, and attain considerable height. If you would say the dimensions of the conservatory, the degree of heat that may be obtained, I should advise you better. I should not really advise you to get such things as *Brownias*, if you have neither the space nor the means at command to grow them satisfactorily. Such climbers, however, as *Bignonia venusta*, *Bougainvillea glabra*, *Jasminum gracillimum*, *Passiflora princeps*, *Plumbago capensis*, and its beautiful white variety, *Stephanotis floribunda*, and the *Tecomas*, would also succeed as climbers if there is a fair amount of heat; but if it is a cool conservatory the *Hebrethamnua* would do well, *H. elegans* in particular, and such very beautiful things as the *Lepagerias*, both alba and rosea, which succeed well under ordinary conditions and give welcome sprays of white flowers in the former kind and in the latter rose. They want a border of peaty soil, and will grow in a quite cold house. You should be able to succeed well with these climbers, that will cover the roof in time. In a constantly damp place, shady too, nothing will grow well. *Pelargonium*, *Hestbe*, *Chorozeamas*, and other things cannot stand such conditions, nor the varied coloured-berried *Per-nettyas*. They all need a drier atmosphere than you can apparently give them, but Ferns may be encouraged more. If you wish the place to be gay you can fill it from another house with things in season, or plant out *Camellias*, *Azaleas*, the very beautiful *Acacias*, such as *A. dealbata*, perfect mountains of flowers in spring; but these require more a temperate house than a damp conservatory. Send a few more particulars as to the heat maintained, and then I can advise you better as to the selection of stove plants.—C. T.

3958.—A rusty plug in a boiler.—I do not know what object you have in wishing to take out the rusty plug, except it is for the purpose of cleaning out the boiler. If that is the only reason I advise you to leave it alone. It may be desirable to clean out the sediment that collects in a boiler, but I do not think it is so necessary as to require you to have the plug bored out. It may be neglected, but I have known the plugs inserted in many different forms of boilers, but somehow or other they never get used; yet the boiler has been none the worse for it.—J. C. C.

—Try giving the head of the plug a few blows with a rather heavy hammer. If this does not loose it, hold a red-hot piece of iron to the plug for a few minutes. A few drops of paraffin-oil poured round a rusty bolt or screw will also often loosen it in the course of a few hours.—S. C. R.

3967.—Treatment of a Myrtle.—A mixture of loam, leaf-soil, and peat, two parts of the former to one of the two latter combined. Plunge the pot in coal-ashes, extending the bottom on tile or piece of slate to make sure the worms do not enter the pot. Supply the roots with water as required, and syringe the leaves nightly after a hot day. By exposing the plant to the full sun's rays the wood will be matured and possibly give a crop of flowers next year. Plants that make strong shoots from the base, however, do not always flower from this part for a year or two until the wood has become thoroughly ripened.

—You may stand the plant out during the summer, and Vines specimens in tubs are very

handsome, and well adapted for terraces, especially if Agapanthus are also used. In quite the southern counties of England the Myrtle will succeed in the open, but even then gets cut in winter. You may put out the plant during the next few months, keeping the soil moist, and stand it in a moderately shady position. There are several varieties, but no doubt yours is the type. As regards soil, a light loamy compost, not too heavy, but medium in texture will suffice, and put a few crocks in the bottom of the pot for drainage. The variegated varieties are pleasing. Take in the plant early in September, and keep it through the winter in the greenhouse or conservatory. It is a pity such fragrant-leaved things are not more grown in gardens.—C. T.

3912.—Painting hot-water pipes.—Jamp-black, mixed (as paint) with boiled oil. Two thin coats will dry hard and bright in four or five days.—Knox.

3953.—Sulphur for mildew.—The only certain way to cure mildew on Grapes in either a heated or unheated structure is to dust the affected parts with sulphur. If the bunches are badly infested with mildew over those parts with sulphur. That of a brown colour is best, it is less seen than the ordinary kind. In a few days the mildew-spores will be killed. A few sharp puffs of wind by the aid of a pair of bellows will generally dislodge the sulphur. The stems of the Vines should be coated over with sulphur also, made into the consistency of paint by dissolving it with cold water. If the mildew is perceptible on the leaves dust the

COUNTRY HOUSES.

OLDSWINFORD CASTLE, STOURBRIDGE.

ANYONE who admires fine country houses will find pleasure in a ramble in the vicinity of Stourbridge, a town that has in itself many quaint and interesting features. Oldswinford Castle, the home of J. Evers Swindell, J.P., is placed in this picturesque portion of the once-too-beautiful county of Staffordshire. A glance at the accompanying engraving will show that it is a house of solid architecture, many-angled, and far more imposing than some of the erections of recent date that are often purrile imitations of the most famous "homes of England." There is something more than architectural beauty in Oldswinford Castle, and that is in the many kinds of creepers that hide the bareness of the walls. A house without greenery to relieve its harsh, cold outlines loses much of its old-fashioned aspect; but here we have Jasmines, Roses, Japanese Honeyuckles, the pink and white-flowered Pyrus japonica, and last, but not least, the glossy Ivy; that, as will be seen by reference to the illustration, has overgrown completely the two outside chimneys. We wish that Ivy were more used to hide ugly angles, chimneys, and unsightly corners, as there is certainly nothing that can be used with better effect. Some, let us hope, from a mistaken notion of the character of the finest of overgreen climbers, tear it from the walls, and we could cite instances of folly of this kind. But it neither promotes damp, dry rot, nor any other evils that are supposed to accrue

ORCHIDS.

THE TWO BUTTERFLY ORCHIDS (O. PAPILIO AND O. KRAMERIANUM).

THESE two plants are called Butterfly Orchids, and they will maintain the appearance of those insects. My friend, "O. Hedley," seems to be somewhat mixed in these matters, and he sends me what he calls "the true Butterfly-flower," but I must set him a little bit more straight than he appears to be in this matter, because the flower sent is *O. Kramerianum*, which, although one of the discoveries of the famous Polish explorer and collector, Warszewicz, is not the original Butterfly Orchid, and, consequently, cannot be called the true plant, for *O. papilio* was introduced into our gardens just upon seventy years ago from the Island of Trinidad, I believe. And although the plant may have become established in the woods of that island, I think it is open to very great doubt if it is really a native of that place, as I was told many years ago by a friend who travelled in Venezuela and Caracas, and sent many *Cattleyas* and other Orchids from these regions, that he found many *O. papilio* in the latter country, and who also told me that communications with the mainland and the Island of Trinidad were very frequent, and it, therefore, causes me to doubt if the plant is really indigenous to the island; but if it is so or not does not detract in the least from the beauty of the Orchid. I must say that it really is one of the most beautiful forms of the flower which has come under my notice. Now I must say a few words about the management of these plants, and I know only of one other Orchid that can be associated with these, and that is the little *O. Linnæi*, of which not much is known. The other members of this section of the genus have great attractions for the amateur Orchid grower, and I have observed many to select good and brilliantly coloured forms with much keenness. Now the first kind named, *O. papilio*, requires a greater amount of heat than many plants from about the same latitude, and I have found them to succeed best when grown in the East Indian house, but they require a nice moist atmosphere, and I like to grow them upon a good-sized block of wood or in a shallow basket, and to keep it from being overloaded with mould about its roots the plants should always be hung in the sun, but do not let the sun, when too powerful, shine full upon it. The other species, *O. Kramerianum*, which my friend appears to be so proud of, I have always found to succeed best when grown a good hit cooler, and I have found it to thrive best until it has become established if treated to more shade than *O. papilio*, but this plant also is best when grown upon good-sized blocks of wood. Avoid the thin, cut-down blocks which have become so very popular with a great many in the trade.

MATT. BRAMBLE.

COMPARETTIA MACROPLECTRON.

THIS very beautiful Columbian plant was introduced here by Messrs. Lowe and Co., of Clapton, some fifteen years ago, and now I have an excellently-coloured variety of it sent me from the West of England from "M. J. T." asking me to say a few words about it? Well, I can say that it is a very free-flowering plant, and the flowers last a considerable time when they have expanded, and, moreover, that it is the largest-flowered kind in the family, so that I cannot say anything against the plant whatever. The plant usually flowers about the month of July, so that the specimen of "M. J. T." is flowering a month before its time, which, I suppose, however, is caused by the earliness of the season. This plant grows upon trees in its native home. It is an evergreen, and it produces its drooping spike from the base of its small bulb, which usually bears a single leaf some 4 inches in length. The flowers are about 2 inches across, and of a beautiful soft rose-colour, spotted and tinged with rosy-purple. The best plan to grow the plants is to use for its accommodation small, shallow, earthenware pans, drained well, using soil some good peat-fibre and chopped Sphagnum Moss; but do not use much soil about their roots, and this should be changed annually just before the plants begin to grow. They should be hung up in the full light; but they should not be exposed to the sunshine, but a light

Oldswinford Castle, Stourbridge.

affected parts also with sulphur. Mildew in vinerias is generally caused by draughts of cold air. Opening both top and bottom ventilators when the Vines are in bloom is the most frequent cause of mildew. If this be the case with "Leopardtown's" Vines I should advise him to close the front ventilators for a time and keep the atmosphere inside the house as dry and as buoyant as possible, so as to avoid a stagnation. Sulphur sprinkled about the floor and border of the house will assist in driving away the mildew pest.—S. P.

—Sulphur dissolved in water and applied with a brush to hot-water pipes will destroy mildew, but the pipes must be made so hot that the fumes will be strongly felt in the house; it will in this condition destroy red-spider on the leaves as well. As the house is unheated the sulphur must be puffed upon the leaves with an appliance the seedsman sell for the purpose. There are various kinds of sulphur dustors, but a good thing may be made by putting some in a muslin bag, and as the bag is shaken the sulphur flies out in a fine dust on to the leaves where the mildew is. It will kill the parasite wherever it touches.—J. D. E.

—In an unheated house dust the sulphur on the parts affected with mildew. In bad cases this is the best way of applying it. Where the attack is slight mix sulphur in water and syringe the Vines with it. Mix the sulphur with a small quantity of water first, and then fill up the pot with water. When the mildew is destroyed the sulphur can be washed off with the syringe.—E. H.

—Scatter the sulphur on slates or sheets of iron or tin, and place them where the sun shines full on them, and the house will soon be filled with the mildew fumes.—E. C. R.

from its use. The widespreading lawn in front of the house is another feature we are pleased to see, but would rather have had the mass of shrubs in front of one of the principal rooms removed; it looks like a patch on a beautiful carpet, and hides a full view of the house. Travellers by rail to Worcester will have an excellent and picturesque glimpse of Oldswinford Castle between Stourbridge and the famous cathedral city.

3959.—Carnations, &c.—Young plants of *Souvenir de la Malmaison* produce quite as large flowers as the old plants if they are well established and grow under the same cultural conditions. The plants may have been poor weak things, and have not been long enough established in the flower-pots. They should be well established in flower-pots early in the autumn, and if good soil is used and the plants are repotted into larger flower-pots in the spring, in a compost of good yellow loam three parts, one part decayed manure, one part leaf-mould, and a good sprinkling of sand, the results will be highly satisfactory.—J. D. E.

—My experience of Carnations is that the young plants produce fewer but decidedly finer blooms than the old. This holds good with many other perennials; for instance, the year-old plants of *Delphinium formosum* produce flowers at least half as large again as well established clumps.—A. G. BULLOCK.

3961.—Blood as manure.—Blood is a powerful stimulant, but it does not mix well with water unless obtained quite fresh. Should be very much diluted. I have used it at the rate of one of blood in six of water for Vines, Tomatoes, and other things growing in borders, but I think it should be still further diluted.—E. H.

shades should always be in readiness to be run over them in the case of sunshine. They enjoy a moist atmosphere, and during the summer season they enjoy an abundance of water, and even during the winter season this beautiful little plant requires careful watching, and should be kept just moist. A great mistake used to be made in the management of this pretty, and, for the most part, gay-coloured family of plants, by growing them in too hot a temperature; but I have found them to succeed best and to flower freely when grown in an ordinary stove, and this plant in particular enjoys a cool temperature and grows well enough if it is kept free from a little white scale which is apt to get down into the sheathing bases of the leaves, when if this is allowed to remain undisturbed, it will soon undermine the health of the *Compansettias*.

MATT. BRAMBLE.

ROSES.

A HARDY WHITE ROSE.

DURING the past three winters I have had a plant of a White Rose that has braved the cold weather unharmed on the north front of my house, where the sun never shines; and as I write, on the first of June, it is as vigorous and as full of flowers as ever I saw the same Rose in any other position. Its name is *Mme. Plantier*, an old Rose that, for fragrance and the purity of its colour, is not surpassed, if equalled by, any other, new or old. I do not wish to claim that I have discovered anything new in the behaviour of this Rose; its hardy character may perhaps be known to some people. I do, however, say that until the last two years I should have looked with suspicion upon the advice had I seen it recommended for planting in a north aspect. There could not be a colder position than the plant I refer to occupies. So that no one need fear to plant it for covering a north wall or fence, and if they are fond of sweet-smelling Roses they will not forget it. By the way, there is another old Rose that has delighted many of my friends lately on account of its exquisite fragrance and delightfully-formed flower-buds. I allude to *Blairi No. 2*. The colour is pink, and it does well for covering low walls, or as a standard, if not hard pruned.

J. C. C.

3973.—*Marechal Niel Rose in a vinery*.—I can only suppose the reason that your plant did not flower was the wood was insufficiently matured. When growing on the back wall of a vinery the dense shade afforded by the vines in such a late house as yours would preclude an early ripening. Probably, too, you started fire-heat late in the autumn to assist in finishing off the Grapes. If so, you naturally kept the sap in the Rose on the move more or less all the winter. The strong growing Roses all want a short period of complete rest. I would advise your letting the plant grow at will, and trust to its getting better ripened owing to such an early ripening.—P. U.

—When you better understand the behaviour of this Rose, you will not regret that your plant did not flower this year. Had it done so it would not have made the long shoots of which you speak. If you can get the growth it is now making well ripened you will get a flower at every joint the whole length of these shoots next spring. From this you will learn that the young shoots should not be cut off. I am afraid, however, that you will have some difficulty in ripening the growth, as winter wool was the cause of its not flowering this season. The same thing so often happens when the growth of this Rose is trained on the back wall of a vinery that I never recommend it being so trained. A good deal, however, depends on the amount of light that reaches it.—J. C. C.

3975.—*Roses, &c., in a greenhouse*.—As you want Roses for cut-flowers only, I would discard both *La France* and *Star of Waltham*. Replace the former with *Mme. Falcot*, and the latter with *General Jacqueminot*. These are really good. Here are a few more good varieties that are not climbers: *Niphetos*, *Anna Ollivier*, *Homère*, *Luiole*, *Safrano*, *Sunset*, *Innocente Picola*, *Mme. Hoste*, and *Perle des Jardins*. If you have a back wall it would be best to use a climber. In that case *William Allen Richardson* or *L'Idéal* should succeed your present

admirably. Purchase them in pots, and pot on according as your judgment guides you—say, every two years after they have attained to a 10-inch pot. The health and size of the plant must be taken into consideration, and it is not safe or easy to lay down a hard-and-fast rule. Do not shake the soil from the roots. Remove the bottom crocks, also any loose soil, and as much from around the crown of the plant as is possible without disturbing many of the roots. No; it is not essential to have yellow-loam. This is excellent, certainly, but difficult to procure. Almost any good loamy soil containing a fair mixture of decayed vegetable matter and dung will do as well. A cold frame, such as you suggest, is the best place of all to winter them in. Bring in the most forward first, but in such a small structure I would use them in one batch, and as the varieties I have named continue to bloom in successional crops I think you will find that a much better plan in your case. Prune at the end of November; stand them in the frame to keep them there until the middle of January. They will then be swelling out, and come on rapidly when introduced to heat. Your house is very small for miscellaneous plants, and Roses will need a lot of attention to keep them free from insect pests under such circumstances.—P. U.

3976.—*Marechal Niel Rose in a greenhouse*.—You are treating your Rose very well indeed, and may continue on the same line for some time to come. Confine the new growths to three shoots, and get these as strong as possible; you can soon see which are going to grow away the strongest. By the end of September let your plant have as much air as possible. This should not be difficult, because your house will be comparatively empty until such subjects as *Azaleas*, *Bouvardias*, &c., are housed again from the open. If you can secure wood fairly well stored you may be certain of a good crop next season.—P. U.

—I do not see that your treatment can be improved upon, and I should say you are likely to reap a full measure of success with this Rose. Seeing that it has made good growth already, continue to give manure-water in dry weather up to the end of August. The young shoots should be trained to wires, which should be about 9 inches apart and 1 foot from the glass. Before winter sets in you must protect that part of the stem that is outside the house. This is best done by wrapping some haybands round it. The surface of the border should also be covered in the winter 3 inches thick with long dry litter or tree-leaves. You may leave the shoots their whole length or cut off the soft-green tops about the end of November.—I. C. C.

The Hybrid Perpetual Rose.—I have been sometimes asked to define a Hybrid Perpetual Rose—to say what it is and where it comes from. This is a very natural question, as it is more largely grown than any other section, although the Tea-scented flowers are strong rivals in popularity. It may interest readers of *GARDENING* to know that Mr. Wm. Paul, of Waltham Cross, in his lately-published "Contributions to Horticultural Literature, 1843-1892," mentions: "I do not think it is possible to say when the first Hybrid Perpetual Rose sprang into existence. It is much easier to speak as to the origin of the group. It is descended from the Four Seasons' Roses (*R. damascena*), through the *Damask Perpetual* on the one side and the *Gallica*, *Hybrid China*, *Bourbon*, and almost every other group on the other side. If we go back to the year 1812, when the *Rose du Roi* was raised in the garden of St. Cloud, near Paris, we shall find in that variety a marked divergence from all pre-existing kinds, and the compilers of catalogues of that day must have been puzzled where to place it. Apparently a hybrid between the *Damask Perpetual* and the *Gallica*, it was grouped with the former because it produced flowers in the autumn. M. Vibert's catalogue of 1820 offers eleven varieties of Four Seasons' Roses, among which is *Palmyre*, raised in 1817, and following, except in point of colour, the *Rose du Roi*. Then and later on a few others might have been called Hybrid Perpetuals. In 1844 was published '*La Rose, &c.*,' by J. L. A. Loiseleur Deslongchamps, in which '*Rose Perpetuelle remontante*' figure as a separate group by the side of *Damask Perpetuals*. These and others form the Hybrid Perpetual of

the English catalogues." Thus in a nutshell is given a brief outline of the beginning of the splendid race of flowers that attract thousands to the Rose shows held throughout the length and breadth of England.—C. T.

FRUIT.

3957.—*Fruit-trees and insects*.—First go over the trees and take off a few of the badly attacked shoots and leaves, and then dust the affected parts with Tobacco-powder. Syringe with soap-suds or soft-soap and water in twenty-four hours after the Tobacco-powder has been used. This will clear off a good many of the insects, but not all. Repeat the Tobacco-powder dressing and syringing until the trees are quite clear. There is no better or cheaper way of cleansing fruit-trees.—E. H.

—If you had mentioned the name of the insect that you say spoils your fruit, one might have helped you with some useful advice. It seems to me that it is woodlice that eat your Apricots, Peaches, and Nectarines. These break the skins, and then ants follow them in their work of destruction. If it is woodlice you will find them in the crevices of the wall, from which they should be dislodged. Hollow Bean-stalks placed amongst the branches will afford these insects shelter, and if the stalks are examined once a day you will be able to kill a good many of your enemies.—J. C. C.

—I presume the felix is attacked mainly by the aphid family. This pest is the most troublesome this year, and decidedly the worst to get rid of. Syringe the trees in the evening with the following mixture, thoroughly wetting every part, and well wash the foliage the next morning with clear water. Well soak 2 lb Tobacco-paper in hot water, pouring off the liquid several times to extract all the strength from the paper. Dissolve 3 lb. soft-soap in hot water to the ingredients named, add 40 gallons clear water, apply with a fine-roset syringe in preference to the ordinary rose, with a view to economising the mixture. If used at a low temperature of 60 degs., it is more effective than when used cold.—S. P.

3972.—*Treatment of a Cherry-tree*.—The tree is making growth too fast; it needs root-pruning to check its progress. At the end of September is the best time for this treatment to be carried out. Dig out a trench 1 foot wide all round the tree 4 feet away from the stem, and as deep as roots are found, cutting all off that are come in contact with. This will have the effect of inducing fibrous roots to be made, which are really the feeders of the tree. Long fibrous roots only tend to luxuriant growth, and as this cannot ripen thoroughly the tree cannot produce a crop of fruit. Maturation of the wood is of the first importance in all fruit cultivation, and without it no hardy fruit can be a success. Do not allow the shoots to over-crowd each other, but give all space to mature in the autumn. Nothing less than 2 inches ought to be allowed for new growths. Do not give manure in any form to the tree as it is too luxuriant already, but if there is any suspicion of the roots being dry, give them a thorough soaking of clear water. Remove all suckers from the base as fast as they show above the surface. When root-pruning in the autumn, if no roots are found within 6 inches of the surface, the soil ought to be removed and the roots lifted, so that they have the benefit of warmth from the sun.—S. P.

Strawberry "Noble".—This would be indeed a fine variety, "barring the flavour," as expressed by "B. C. R." in *GARDENING*, p. 212, but it is precisely flavour that one wants. I do not care whether a plant is phenomenally productive, vigorous, and with large, handsome fruit; if it does not possess fine flavour it is comparatively valueless. I have just tasted some fruits of this variety, but they were far from satisfactory—watery, and without the true Strawberry flavour that one gets in British Queen, for instance, or even President. Noble is early, and to be got under circumstances quite against other kinds, but flavour is certainly the more important consideration. Perhaps Mr. Laxton, who, I believe, is the raiser, will in time raise other Strawberries with all the good qualities of Noble, and of brisk, pleasant flavour.—C. T.

TREES AND SHRUBS.

THE MAGNOLIAS.

There are about a score species of Magnolias known to botanists, and all but some half-dozen or so are in cultivation in this country. The head-quarters of the genus are in China and Japan, a few are peculiar to the Himalayan region, and a few more to North America. All are handsome and desirable trees or shrubs; some, indeed, may be classed with confidence amongst the most beautiful objects to be met with in the gardens of temperate climates. A glance at the accompanying engraving, representing a very fine specimen of the Yulan (*Magnolia conspicua*) of China and Japan, will show what glorious effects may be obtained in spring in the South of England, at any rate, by its use. It is true enough, unfortunately, that frosts sometimes injure the flowers, and change their snowy whiteness into an unsightly brown. Perhaps the reason that this Magnolia and its allies are not more frequently met with in gardens is owing to the fact of their not transplanting readily. The best results obtain if the plants are procured and planted just as growth begins in spring. The fleshy roots when injured rot rapidly, and when autumn planting has been practised, very many individuals succumb to the ordeal, those that do not do so outright often struggling on in a pitiful plight for years. A little care in transplanting in spring, in sheltering with mats from dry winds or hot sun, and in syringing the wood to prevent shrivelling until the plants are thoroughly established, would do much to prove that the Magnolias can be planted with every prospect of success. Some species occasionally ripen seed freely in this country, and it is well worth while to sow this seed at once. If dried and kept like other seeds until the following season, all chance of germination will have passed. All the species of the natural order Magnoliaceae have seeds which retain their vitality but a very limited period.

M. ACUMINATA (the Cucumber-tree of the United States) makes a noble specimen when planted singly in the park or pleasure ground. It is deciduous, the leaves varying from 5 inches to 1 foot in length, and glaucous green, the flowers yellow-tinged, bell-shaped, and slightly fragrant. There are fine examples of this tree at Kew, in the gardens of Syon House, Claremont, &c. In its native habitat it attains a height of from 60 feet to 90 feet, with a trunk from 2 feet to 4 feet in diameter. The Yellow Cucumber-tree (*M. cordata*) is regarded by Professor C. S. Sargent in his magnificent work, "The Sylva of North America," as a variety of *M. acuminata*. It is a rare plant in a wild state, as it does not appear to have been collected since Michaux found it in Georgia.

M. CAMPBELL, one of the most gorgeous of Indian forest trees, has not fulfilled the expectations of those who took so much trouble in introducing the species to British gardens. In a wild state it attains a height of 150 feet, and the fragrant flowers, varying from deep rose to crimson, are produced before the leaves appear. Probably the finest specimen in the British Islands is the one at Lakeland, near Cork, which ten years ago was 35 feet high. Perhaps Mr. Gumbleton would be good enough to inform us what progress the tree has made since then. In 1884 it flowered for the first time, and a figure was prepared for the *Botanical Magazine* from

material forwarded to Kew by the late Mr. Crawford. Considering the beauty of *M. Campbell*, it would appear worth while to treat it as a well plant against some high building in a warm, sunny position. As it occurs in a wild state along the outer Himalayas, at elevations of from 800 feet to 1,000 feet above sea-level, there seems every probability that the treatment suggested would prove successful.

M. CONSPICUA.—In its typical form this has snowy-white flowers, which are produced in the greatest profusion in the latter part of April and beginning of May. Splendid specimens of this beautiful Chinese and Japanese tree are to be seen at Gunnersbury House, Syon House, Kew, &c. *M. Yulan* and *M. precis* are names under which this is found in some books and gardens. Several hybrid forms between this species and

creamy-white in colour, and are produced inter than those of any other cultivated species. In a wild state the tree attains a height of from 30 feet to 50 feet.

M. GLAUCA, the Laurel Magnolia or Sweet Bay of the Eastern United States, is a delightful sub-ovogreen shrub, with oblong or oval leathery leaves, bluish-green above and silvery below. The flowers are globular in shape, very fragrant, opening of a rich cream colour, and gradually acquiring a pale-apricot tint with age. In a wild state this species occurs in swamps, and attains a height of 20 feet. A large-flowered form (*M. Thompsoniana*) originated, according to Loudon, about eighty years ago in the nursery of a Mr. Thompson at Milo-end. It is figured in the *Botanical Magazine* as *M. glauca* var. *major*, and in other publications.

By far the most faithful and characteristic representation, however, is given in *Garden and Forest* for 1888. Professor Sargent there says: "It has been considered a large-flowered variety of *M. glauca*, and by some authors a hybrid between *M. glauca* and *M. umbrellata*. It is probable that the latter supposition is correct, as, although the leaves of *M. Thompsoniana* cannot be distinguished from those produced on a vigorous plant of *M. glauca*, the leaf-buds are quite glabrous and destitute of the silky hairs which cover those of that species, while the broad, strap-shaped reflexed sepals and obovate-oblong petals, contracted into a narrow oval, distinctly belong to *M. umbrellata*; the flowers, rather more than 6 inches across when fully expanded, being intermediate in size between those of the two species. They have, on the other hand, the delicious fragrance peculiar to those of *M. glauca*. So far as I know, *M. Thompsoniana* does not produce fruit, and it is a curious fact that it is much less hardy than either of its supposed parents, suffering here always unless carefully protected in winter, and rarely rising above the size of a small bush, although Loudon, . . . speaks of trees at Milo-end more than 20 feet high. I shall be glad to see fruit of this plant, and to learn if it grows more vigorously in Europe than it does in this country."

M. GRANDIFLORA, the great Laurel Magnolia of the Southern United States, is in England best treated as a wall plant; under these conditions it thrives well and flowers freely. In order to form some idea of the beauty of this species it is necessary to see it in large symmetrical, stately trees in the West of France, &c., where climatic conditions obtain which more nearly approach those of its native habitat. In *Bartram's Travels*, that enthusiastic lover of Nature exclaims: "Behold yon promontory, projecting far into the great river, beyond the still lagoon, half-a-mile distant from me: What a magnificent grove arises on its banks! How glorious the Palm! How majestically stands the Laurel, its head forming a perfect cone! Its dark-green foliage seems silvored over with milk-white flowers. They are so large as to be distinctly visible at the distance of a mile or more. The Laurel Magnolias that grow on this river are the tallest and most beautiful that I have anywhere seen, unless we except those which stand on the banks of the Mississippi. . . . Their usual size is about 100 feet, and some greatly exceed that. The trunk is perfectly erect, rising in the form of a beautiful column, and supporting a head like an obtuse cone."

In the *Garden*, Vol. II., page 205, there is a fine illustration of the (*Magnolia grandiflora* at

OUR READERS' ILLUSTRATIONS: The Yulan (*Magnolia conspicua*) in the garden at Gunnersbury House. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. Weston.

M. obovata occur in gardens: of two of these, *M. Lenné* and *M. Soulangeana nigra*, coloured plates have been published in the *Garden*. *M. Soulangeana* has flowers similar in shape and size to those of typical *M. conspicua*, but they are deeply tinged with red; *M. Soulangeana nigra* has dark, plum-coloured flowers. Both these bloom a week or ten days later than the type. Other seedling forms or slight varieties of the Yulan are *M. Alexandrina*, *M. oyathiformis*, *M. speciosa*, *M. spectabilis*, *M. superba*, *M. triumphans*, and *M. Yulan grandis*.

M. FRASERI, a native of the Southern United States, is easily recognised by its light green spatulate leaves, varicled at the base; they each measure about 2 inches or 1 foot in length, and about 3 inches or 4 inches across at the widest part. The flowers, each of which measure 2 inches or 4 inches in diameter, are

Horns." Professor Sargent, in his "Sylvia of North America," adopts the name of *M. foetida* for this species. In *Garden and Forest* for 1883, one writer urges the claims of this species as the national flower, and states that it "was among the favourite trees, if not the special one of Washington. An imposing specimen over 75 feet high, known to have been planted by his own hands, still flourishes at Mount Vernon, and every year, since this modern Mecca has been accessible to the public, each fallen petal of its laded blossoms, every glossy leaf of its rich foliage, and every seed that drops from its fruit pods, have been carried away as precious souvenirs by the visitors to that hallowed spot."

31. *HYPOLEUCA*.—So far as we have been able to ascertain, the only figure of this beautiful species (excepting one in a Japanese publication which is not easily accessible) is in *Garden and Forest*, Vol. I., page 305. From an economic standpoint *M. hypoleuca* is perhaps the most important of all the Magnolias; the wood is straight grained, easily worked, and dull yellow-gray in colour. It is the wood commonly used by the Japanese in the manufacture of objects to be lacquered; it is preferred for sword sheaths, and the charcoal made from it is used for polishing lac. In the southern part of Yesso it is abundant in the forests, and forms fine trees 60 feet or more in height, with a trunk diameter of 2 feet. The leaves are broadly obovate, a foot or more long, and 6 inches or 7 inches wide, dark-green and smooth above, and clothed with white hairs beneath. The flowers are creamy-white in colour, deliciously fragrant, and when fully expanded measure 6 inches or 7 inches across, the brilliant scarlet filaments forming a striking contrast to the petals. There are no large specimens as yet in this country, but as the species thrives well in the North-eastern United States, it is fair to assume that it will do well in Britain.

M. KORUS, a Japanese species, grown in the United States under the name of *M. Thurberi*, is as yet very uncommon in this country, and we have not yet seen it in flower. In habit it seems to approach dwarf-growing forms of *M. conspicua*.

M. MACROPHYLLA.—This, unfortunately somewhat tender in a young state, is worth growing simply for its beautiful leaves, which are green above and clothed with white hairs beneath; they attain a length of upwards of 3 feet. The open bell-shaped fragrant flowers are white, with a purple blotch at the base of the inner petals, and measure 8 inches or 10 inches across. In its native habitat, the Southern United States, it forms a tree from 20 feet to 40 feet in height, with a trunk rarely exceeding a foot in diameter.

M. ORNATA is a native of China; in Japan it only occurs in cultivation. It is a dwarf-growing bush, perfectly hardy in the South of England, and bears freely its purple, sweet-scented flowers, though not in the same profusion as are those of the white-flowered *M. conspicua*. This species has a number of synonyms. Amongst these are the following, which are the most frequently met with in books and nursery catalogues: *M. diicolor*, *M. decudata*, *M. hilsifera*, *M. purpurea*, *Talauma Sieboldi*, &c. There are several varieties, but these differ so slightly from each other and from the type, that descriptions without good coloured figures would be next to useless. The best are *Borreri*, *angustifolia*, and *erubescens*.

M. STELLATA.—An excellent coloured plate of this very beautiful Japanese shrub was published in the *Garden* in June, 1878, under the name of *M. Halleana*. This species is the earliest of the Magnolias to flower, and it should be extensively grown for the beauty of its starry-white flowers. A variety with blue-coloured flowers, sent from Japan by Mr. Marles, has not yet been sent out by Messrs. Veitch, but it grows freely in their Coombe Wood Nurseries, and will doubtless become as great a favourite as the type. Both are dwarf-growing deciduous shrubs.

M. TRIPETALA, a native of the Southern United States, has large, slightly-scented white flowers, from 5 inches to 8 inches across, and obovate-lanceolate leaves from 1 foot to 3 feet in length; in a wild state the tree rarely exceeds 40 feet in height. Philip Miller was the first to introduce this fine species to British

gardens. Other names for it are *M. umbrella* and *M. frandosa*.

M. WATSONI.—A coloured plate of this very beautiful Japanese species was published in the *Garden* in December, 1883, under the name of *M. parviflora*; at that time it had not flowered in British gardens. It is quite hardy. It has large, creamy-white, fragrant flowers, with petals of great substance and deep-red filaments, which add materially to the beauty of the blossoms. The true *M. parviflora* is probably not in cultivation in Britain. N.

WHITE AZALEA INDICA AT COOLBURST.

THERE are few plants or shrubs in our gardens that will produce such an intensely white mass of blossoms as this; consequently, the effect which it creates when seen flowering as shown in the engraving on p. 223, is to a great extent different from most of the things usually met with. Few plants give so little trouble when once established, and even though the late frosts may now and again spoil the beauty of the flowers, yet in the intervening years it is something to be grateful for. I have before this called attention to its habit of growth when planted out and left alone, not much more than 3 feet or 4 feet in height, dense-growing and spreading, neither suggestive of a white umbrella lined with green nor of a gigantic sugar-loaf which has been packed in coloured wrapper, as some of the much-praised inhabitants of the Azalea-house usually are. The engraving shows part of a bush 10 feet across with a shadow thrown over the upper part by a tree of *Magnolia acuminata*, which grows at the side. On the south-east is a large clump of *Rhododendrons*, &c., completely cutting off the morning sun, and behind it are *Hollies*, *Rhododendrons*, and *Spiræa flagelliformis*. This, perhaps, may give some idea of the position it occupies and apparently is satisfied with—namely, shelter from cool winds and too fierce a sun on the flowers or on the roots. Anyone who intends to plant this Azalea should remember that it flowers naturally at a time when there may still be late frosts and cold winds hovering about, and that it would be a mistaken kindness to choose any place, such as under a south wall, which would tend to make the blossoms open earlier in the season. We have some plants under a north wall which do admirably, but they seem to like association with other things, and not to be spotted out by themselves in the open. The variety which does best here is the old typical white. Overgrown plants of other colours from the greenhouse have been turned out sometimes, but they do not seem so happy or produce so good an effect. I cannot but think that a good race of hardy sorts might be raised either by hybridisation with some other species or by careful selection of sturdy growers. It would be worth while, as the effect produced by *Azalea indica* is far more distinct from that of *mollis* or any similar variety than one might expect. The photograph from which the engraving is made was taken last year, not because the bush was flowering more freely than usual, but because an opportunity presented itself by the kindness of a worthy friend. C. R. S. D.

3952.—*Evergreen under Limes*.—I am afraid you will not get Evergreens to grow under Lime-trees if the latter are already established in the soil. The case would be different if the trees and the Evergreens were planted at the same time. The Common Laurel is the only subject likely to suit you; even for that you ought to put a loam in depth of good soil over the border to plant them in. If you would be content with shrubs of a lower stature you would be more likely to succeed with such Evergreens as *Aucuba*, *Green Holly*, *Box*, *Yew*, and *Euonymus*.—J. C. C.

—There is nothing so good as Common Laurels for planting under trees where an evergreen growth is required. It would be useless, however, to plant even Common Laurels if the site was not well prepared for them. For every tree a hole 2 feet wide and 18 inches deep should be taken out, thoroughly breaking up the bottom of the hole. Add manure freely when planting, and mulch the surface afterwards with well-decayed manure, not only to keep the soil warm during the winter, but also in the

summer, and to prevent the evaporation of moisture. Early in October is the best time to plant, the roots then have time to make a start before severe weather sets in, especially the cutting winds of March.—S. P.

—Hollies would make a splendid background, but would be a long time in growing to the height of 10 feet. If the Limes are not crowded, the *Larson Cypress* or *Thuja gigantea* might do. *Portugal Laurel* or *Evergreen Oaks* will also be suitable.—E. H.

—Hollies, *Myrtles*, and *Privet* will answer your purpose; but you must not expect them to grow to the height of 10 feet in one year, or to leave off growing when they attain that height.—A. G. BERRER.

3963.—*Shrubs near a drive*.—If the shrubs have much over-grown the drive they should be cut back in the spring, about the end of March—that is to say, if you have to cut back to the old hard wood. But if a slight trimming will get them back efficiently they may be dealt with at once. Whether you cut back the *Rhododendrons* little or much it will certainly prevent their flowering the next year. The syringe can be dealt with at the same time and in the same way as the others. As a rule, it is better to do such work in the spring.—J. C. C.

3971.—*Caterpillars in a shrubbery*.—If I am afraid you cannot get rid of the caterpillars other than by hand-picking, no ordinary syringing will do any good, as the water will not penetrate the web. I fancy a smouldering fire made up under the trees which will give off an obnoxious smoke would be more likely to penetrate the rolled-up webs and dislodge the insects. The plant you allude to must be, I think, the *Spindle-tree* (*Euonymus europæus*); in some districts this is also called *Squer-wood*. Although a native, it is a very pretty tree in early winter.—J. C. C.

—The caterpillars are doubtless, from your description, those of the *Lackey* moth, and half the battle in dealing with such pests is to destroy the eggs that circle the young branches. You can see them in the spring, and then is the best time for action. I should give the bush a thorough syringing with paraffin, say, an ordinary wineglassful mixed into about five gallons of water. It is necessary to thoroughly dilute the paraffin, and I think this will be proved a remedy; but possibly the caterpillars have by this time devoured the leaves. This is the pest that proves so mischievous to Hawthorns, and also the Apple. A quick way is to handpick them, dropping the webs into hot water; but this is not, of course, so cleanly a process as syringing.—C. T.

3925.—*Gardening for profit*.—Presuming that you intend to dispose of the produce in the neighbourhood, you must in the first place make yourself acquainted with its requirements. Vegetables of all kinds are, of course, in demand; fruits are sure to be wanted, and you cannot err in planting a good breadth of such Strawberries as *Noble* (early), *Paxton* (main crop), and *Marshall McMahon* for late bearing. Black Currants are always wanted for preserving. I should also grow some of the best early flowers for cutting, such as *Pinks*, *Carnations*, *Roses*, *Cornflowers*, *Pyræthrums*, *Perennial Asters*, &c. The profit per acre will depend on the culture and prices obtainable.—J. C. B.

Gathering flowers.—There is a right and wrong way of gathering flowers. As a rule, they should be gathered before fully expanded, especially in the case of such things as the *Iris*, which, when picked quite in the bud state, open perfectly in water, and the same remark applies to the *Peony*, not a very likely flower from its aspect to open in water. Cut the flowers of all plants early in the morning when the dew is upon them, as if picked in the midday, when dried by the sun, they soon fade in the house. Always keep the water constantly changed, and remove a little bit of stem each day. Avoid crushing them in any way, and though a good bowlful is attractive, there is no need to press the flowers close together so as to bruise them. They will keep fresh longer in a cool room than in one that is hot, dry, and lit up at night with gas. These few hints may be of use at this season, as the garden is now gay with colours, and everyone tries to have flowers in the vase. Sometimes they are purchased in the market, and it is wise to avoid the expanded flowers. Buy those that look fresh, even if not fully open. V. C.

OUTDOOR PLANTS.

THE PLANTAIN LILY.

FOR gardens in general, whether small or large, and especially those near large towns, where it is difficult to get anything to grow satisfactorily, the Plantain Lily or Funkia is of great service. It withstands with impunity the trials of town-life, and their fine foliage is always a pleasure to look at. I remember two specimens of *F. ovata* that stood for years in a garden at Lexington, and increased in beauty each season, although very little trouble was taken with them in the way of culture. The leaves were kept sponged occasionally and the plants kept well watered, a necessary thing in a hot and dusty forecourt. The flowers are not so noteworthy as the leaves, and the finest kind is *F. grandiflora*, on which several notes have recently appeared in GARDENING. The Funkias are natives of Japan, and good, bold groups are made of them in some of the London parks,

of note, the leaves being well marked, not spotty or blotched, a very objectionable type of leaf-colouring. *F. Fortunei* reminds one strongly of *F. Sieboldi*, and is strong in growth, whilst the leaves are glaucous in colour, and very pleasing. Of course, one does not want a large collection of Plantain Lilies in a garden, and there is *F. subcordata* and *F. lancifolia*. Of the latter there are several very good variegated kinds, such as *undulata variegata* and *alba variegata*, which are very pleasing in petal. A few of these plants in a greenhouse are an attraction, making good tufts of foliage, and they look well in the lower parts of the rock garden. It is difficult to know why the Funkias are not more grown in small gardens. They are not well grown, I think, but when in gardens it is found difficult to get plants to grow well. The Funkias should be thought of *F. ovata* or *F. Sieboldi* to begin with. They require ordinary soil. C. T.

3950.—Unproductive border.—If the border could be broken up and the soil improved

Asphodelus luteus, Violets, Snowdrops, and many of the spring-flowering bulbs. A large number of things would grow in partial shade if the soil is fairly moist and of a substantial character. But stones will not support life, except a few weeds that one does not care for. If the ground is good and kept moist, not overrun with Laurels, you might make an interesting spot of this border. The Christmas Rose would succeed, and this is a host in itself, with its many charming varieties, whilst you could also have several kinds of Primrose, good, brightly-coloured forms; but you must remember that this cannot be attained if the soil is hot, dry, and the border absolutely covered in with trees. —C. T.

—The best thing you could do would be to throw the soil out against a coarse sieve, and thus get the largest stones out of it. As it is, you can grow Solomon's Seal, German Iris, Brocken (if planted in a little peat), and various Stonecrops; but if you get rid of the larger stones many other things will do well in it.—A. G. BURTON.

3948.—Good lawns.—To have a good lawn you must first have a good soil from 9 inches to 1 foot in depth. Having secured a good soil, the next thing to do is to get turf with a fine herbage and to lay it down in a proper manner, or, after the land is well prepared, you may sow Grass seeds in the spring. In either case coarse Grass and weeds must be weeded out, but first bear in mind you cannot have a lawn that will appear in good condition in all sorts of weather without a pretty good depth of rich soil on the surface. Such weeds as Plantains and Dandelions should be first dug out and the hole so made filled up with petroleum, which is just as effectual as using any kind of poisonous acids, without the attendant risk. In every case where the Grass is thin owing to the poverty of the soil, a good dressing of rotten-manure laid on in November will do much good.—J. C. C.

—After repeated trials with various suggested remedies I find that digging up the weeds by the roots in the easiest way is the best plan. Fill up the holes caused by the weeds with fine soil, in which at the time drop a few seeds of suckling Clover; this quickly germinates and makes green the bare patches. If the lawn is infested with Moss, scratch the surface with an iron-toothed rake, sow on wood-ashes, soil, and lime, two parts of the former to one each of the latter. Cut the Grass weekly with a lawnmower and roll it down as often as possible when the weather is favourable. Lawns are like gravel paths—they cannot have too much rolling, provided it is done at the right moment—directly after rain.—S. P.

—To get a good lawn, the ground must be thoroughly well drained and the turf of the best; also it must be well laid. Half the questions received about unsatisfactory lawns may be answered by saying they are badly drained. You complain of weeds—Daisies, Moss, Dandelions, &c., I presume. As regards weed-destroyers, acids and like applications, they must be used with extreme care, otherwise havoc will ensue. Vitriol I should never advise being used on a lawn, although it is efficacious on garden paths that are very weedy. The old-fashioned plan of digging the weeds, Daisies, &c., out by the root with an old knife or bit of iron is excellent. To get out the root, the surface may be scratched with a rake and the ground sprinkled with wood-ashes or leaf-soil. Of course, the spring is the best season for this work, and any serious alteration in the turf now would prevent its use for this season. A good thing is to sprinkle over some well crushed nitrate of soda, as doubtless the reason of the Daisies coming up is poverty of the soil. If the lawn is very bad, but you want to play tennis upon it for the summer, I should thoroughly overhaul it this winter, relaying the turf and putting down good drainage of coal-ashes.—C. T.

—I am not sure there is much gain in using sold after digging the weeds out. A boy or woman can do the work. But what ruins lawns is neglect in the mowing, leaving the weeds to seed. Let the Grass go without mowing for a month, and there will be weeks of labour in weeding.—F. H.

3962.—Allotment garden.—By all means bury the turf as digging proceeds; it will be far more beneficial to the land used in that way than either burning or stacking in a heap. The land ought to be trenched 2 feet deep, to commence with, taking care not to bury the turf more than 9 inches deep from the surface. Keep the soil from the bottom of the trench still in the same position when broken up, and preserve the

The White Indian Azalea in a wood at Coolhurst. (See page 222.)

where they make fine features, as the foliage, whilst broad, is of a charming glaucous colour, with a delightful silvery tint. Then there is the additional feature of the flowers, which vary from white to soft-lilac. The Funkias, especially the better variegated kinds, are useful to make edgings to large beds, and their hardiness is such that if there is no greenhouse or even garden, merely a backyard, the plant may be grown to perfection. A very fine kind is *F. Sieboldi*, which will grow between 2 feet and 3 feet in height, and the cordate, silvery leaves are very broad. The flowers are very tender lilac in colour, and carried in tall spikes. Of this, as of most of the other kinds, there is a variegated variety, which has the broad leaves edged with a yellow colour. One of the best kinds is *F. ovata*, and may be recommended, as the growth is unusually robust, therefore it is better adapted for town gardens than the others. The leaves are large, ovate in shape, as suggested by the name, and of a good shade of green in colour, whilst the flowers are very pleasing, being of quite a lilac tone. *F. ovata variegata* is worth growing for its distinct variegation, and the variegated forms of the Plantain Lily are for the most part

hardy bulbs might be planted in autumn. Rose of Sharon (*Hypericum calycinum*) would do, and so would the Periwinkles (the small-leaved variegated kinds make a prettiness), Woodruffe, *Anchusa italica*, Foxgloves, Honeysy (Linnaria biennis), Rudbeckia Newmani, Lupinus polyphyllus, *Maripalium rigidum*, and some of the hardiest Peonies would do if the soil is trenched up and made suitable.—E. H.

—Your border is certainly not an ideal spot for flowers, but you may make it more suitable for plants by making it up with some good loamy soil, which will improve matters somewhat. If it is not too shady you might grow hardy Ferns of many kinds, as they like a shady position if not too dense, and in light shade also will succeed well the Spanish Squills, Anemones of many kinds, the beautiful varieties of *A. nemorosa*—in particular Solomon's Seal, a very graceful, hardy plant, with slender stems of white flowers; Winter Aconite, Foxgloves, which look very handsome in full bloom, whilst the leaves are attractive; Daffodils, Day Lilies, the tall and elegant *Polygonum cuspidatum*, Ivies in variety which may be pegged down on the surface of the soil), Lily of the Valley, Iris,

surface-soil exactly in the same place. Now is a good time to put out Brussels Sprouts, Broccoli, Savoys, and Kalas for winter use. Cauliflowers for the autumn may still be planted. Celery, tob, is all in good time. Beetroot and even Carrots may still be sown. A row of Spinach in August would be useful for the winter, and so would Leeks. French Beans, if sown at once, would give a good crop in September; add plenty of manure when planting.—S. P.

— Unless you want the turf for anything particular, the best way will be to dig it in. If the ground is to be trenched, pare the turf off thinly, lay it on one side, and bury it just below the top "spit" of soil; otherwise it may just be turned in, using a long spade, and burying every bit of grass right out of sight. In any case do not burn it. On such ground anything might be grown. Plenty of Scarlet Runners and Dwarf Beans should be sown, also Turnips, Lettuce, Spinach, and Endive. Part of the ground should be planted with Brussels Sprouts, Savoys, Kale, and Broccoli, for winter use, and some autumn Giant Cauliflowers also should be got in at once. It is not too late to sow a row or two of the Ne Plus Ultra Peas, and a few good second-early Potatoes may still be planted.—B. C. R.

— Burning turf is a useful plan. Better trench it in, chopping it up well with the spade.—E. H.

3933.—*Centaurea candidissima*.—This is charmingly effective in the flower garden, and may be used in combination with any other bedding plant. A single specimen in the centre of a small bed, and surrounded with *Alternanthera* and variegated *Mesembryanthemum*, would look very nice indeed, or a row of plants as a bordering to tall growing things will do equally well. This *Centaurea* is one of those things that never seem out of place in any kind of floral arrangement. Cuttings strike very well put in in August or early in September.—J. C. B.

3946.—*White Campanulae*.—The variety you require is the Chimney Bell-flower (*C. pyramidalis alba*). A packet of seed will give upwards of 100 plants, costing but 6d. Sow the seed at once out-of-doors on well-worked soil. If the weather be hot and dry, water the seed-bed the day before sowing the seed; this is much better than watering the bed after the seed is sown, as the soil is rendered hard and caked, making it difficult for the seedlings to push through the crusted surface. Provide some shade for the bed until the seedlings appear above the soil, when the shade should be removed to afford all the available light to the plants to induce a stocky growth, which will enable them to withstand the winter better. When the plants are large enough to handle, transfer them carefully to the position where they are to flower the next year. At the back of the herbaceous border this *Campanula* shows to advantage, or amongst shrubs, where the associated green of the latter harmonises with the pure-white blossoms. This *Campanula* succeeds well in pots and will flower freely in the window or greenhouse, or even under a verandah, or anywhere that provides light and shelter from heavy rains. For pots select the strongest plants, placing them in 5 inch pots; when the roots fill these pots shift the plants into those 10 inches in diameter; in these they will flower. Any ordinary garden soil, with a small quantity of partly-decayed manure, will suffice. Abundance of water is required at the roots when growth is being freely made, and occasional doses of weak liquid-manure will be of service.—S. P.

— There are many beautiful varieties of Bell-flowers bearing white flowers. Taking them in alphabetical order, the white variety of the Carpathian Bell-flower (*C. carpatica*) is very charming, the flowers pure-white, and they look well in pots, whilst it is also excellent for the border. It makes very free growth, and blooms abundantly. Seeds will not bloom the same year, and they may be sown in pots filled with light soil, and placed in a cold frame. You could sow now, but this applies more to the type. Such a variety as *alba* should be raised from the cuttings, which atrika readily in a cold frame, or the plant may be divided. What a lovely thing *C. fragilis* is in pots, which will strike readily from cuttings early in the year. It makes a valuable pot-plant, and I lately recommended it for baskets in windows, than which nothing could

be more suitable. *C. gargaucica* should be propagated by cuttings, or the old plants may be divided to give increase of stock, and is a delightful plant; so as you want white flowers you must get this form. Another fine Bell-flower for the greenhouse is *C. isophylla alba*, which is very charming when on the greenhouse stage, its slender little shoots hanging over and quite covered with the pure-white flowers. And I may here remark that as regards soil it should be made up of light loam and leaf-mould, mixed with sufficient sharp silver sand to keep

Fig. 1.—Turnip "Early Munich." (See page 225.)

it moderately open. Pot moderately firmly, and especially if in baskets in the greenhouse or window, be careful that they do not suffer from want of water. During the winter less water is required than in the summer, but more may be given in the spring, when the plant can then be divided if considered necessary. Plants of *C. isophylla alba* suspended in pots in the greenhouse are beautiful. The shoots droop over gracefully. The Canterbury Bells are very useful for pots, and you may get white forms amongst these. There are biennials—that is, bloom the year after sowing. Remarks have recently been made respecting these in GARDENING. A very handsome *Campanula* for growing in pots is *C. pyramidalis*, and the white and blue when associated together make a charming contrast in colour. It is not necessary to refer again to this type, as it will be found fully described, also treatment given, in GARDENING of June 3, page 191. Then you may add the white forms of *C. persicifolia* and *C. pumila*, synonymous with *C. nepitosa*. I used to grow many pots of it for the greenhouse, and it is quite a gem of its class, the flowers pure-white, quite of a bell shape, and the plant easily divided. A good panful of it in bloom is sure to give pleasure, and it does not exceed 4 inches in height.—C. T.

— *Campanula isophylla* is a real gem for the greenhouse, and the only white variety I should care to cultivate. It is of drooping habit, and a well-established plant will produce a large number of its pure-white flowers for a long time. I do not know if seed of this one can be obtained, but even if it could it would take some time to raise strong plants. The young shoots that spring up in the crown strike root freely, and will flower the same year. Suspended in a light window, there is no more suitable plant for the purpose.—J. C. C.

3998.—*Treatment of Tigridias*.—These are most unsatisfactory bulbs to grow; they either do very well or fail utterly. I believe it is entirely a question of soil, and that in a good fibrous loam with a little admixture of sand they would flourish. I tried them some years since in a prepared bed of peat, leaf-mould, well-decayed manure, yellow loam, and silver-sand, and from a dozen picked bulbs of the lovely *Tigridia pavonia grandiflora alba* I had one miserable bloom, which half opened and then faded. What made matters worse was the fact that at that time the bulbs of this *Tigridia* were decidedly dear, and every one rotted in the earth.—A. G. BUTLER.

— These bulbous plants do not require any special treatment. Here, in the West of England, I can get them to grow and flower in the open air as easily as the *Gladiolus*. It is, however, necessary to start in the spring with sound, plump bulbs; if they are shrivelled through being kept in paper bags or drawers all the winter they will not flower. If they are grown in pots the bulbs should remain in the soil until it is time to repot them in the spring; but from November to March they should be kept pretty dry and away from frost. When *Tigridias* are grown in the open they should be taken up in the autumn, and the bulbs kept in boxes of dry soil until the middle of

April, when they may be planted again. They require a rather light, rich soil, and plenty of water in dry weather through the summer.—J. C. C.

— Perhaps your soil is heavy and retentive, therefore cold; in such soil *Tigridias* will hardly live, let alone flourish. A warm, sandy soil suits them best. In this no special treatment is necessary. Plant the bulbs 3 inches deep early in April; on the surface give a light mulching of leaf-mould to keep the roots cool during the summer. In the case of heavy soil, remove it 18 inches deep from the site where the *Tigridias* are to be grown. A hole 1 foot wide will accommodate three bulbs. Place a layer of broken bricks or clinkers, 3 inches thick, at the bottom, filling up with light soil freely mixed with leaves and sand. In this compost place the bulbs, taking them up again in the autumn when the leaves have turned yellow.—S. P.

— The Tiger-flowers, or *Tigridias*, are a very interesting class of plants, and the time to plant them is in March; the soil should be of a moderately rich, loamy character. The position for them must be thoroughly well drained, and not too sunny, although I have seen the *Tigridias* bloom splendidly on a warm south border where the soil was light, and here the plants made a delightful show, as they were disposed in little groups so as to give an effect in colour. The best soil for them is a mixture of loam, leaf-mould, and sharp silver sand. Plant the bulbs not later than early April, as they suffer from being kept too long out of the ground. Put them in at a depth of 3 inches, and it is a good plan, as in the case of other choice things, to put some silver sand under each root. The flowers are very gorgeous, and the type is *T. pavonia*, and if you wish to indulge in a good assortment of the Tiger-flowers you may select the following (I may mention that *Tigridia* is synonymous with *Torrusis*): The Shell-plant (*Tigridia conchiflora*), the flowers yellow, spotted with red; and there is a variety of it named *grandiflora alba*, the bold flowers white, with spots of crimson. The ordinary Tiger-flower has scarlet blooms, enriched with orange spots; they measure about 6 inches across, and although lasting but a brief time (a few hours), a succession appears over several weeks. *T. canariensis* has yellow flowers, spotted with scarlet, whilst those of *T. speciosa* are yellow, with red spots. A new species is *T. Pringlei*; it is very brilliant in colour, taller in growth, and not difficult to grow if treated the same as the type. Begin first, however, with the typical plant, and then add the others as desired. If the position is warm and the soil light, the bulbs may be left in the ground during the winter; but if not considered advisable, lift them when the foliage has died down, and keep them in a cool place during the winter, as in the case of the *Gladiolus*. Plant out again in spring. One does not see much of the *Tigridias* in gardens, but when in full bloom their gorgeous flowers are sure to please.—C. T.

— *Campanula isophylla alba* is very pretty for basket work, or to hang down from the edge of the stage in greenhouses. It is quite hardy in sheltered spots on the rockery. May be raised from seeds or cuttings, or by division.—E. H.

Carnations.—The fearfully dry weather we have experienced now for so long has had a very bad effect on some plants growing on a light soil, and amateurs have found, no doubt, many of their plants have begun to turn yellow, and what the gardeners call "give up." In these cases it is no use to water, but I have been able to save a great many plants, by, directly I have observed any change in the tint of the foliage, at once taking away the old soil immediately round the plant in this condition, in the form of a basin, and refilling the vacuum with a compost of fresh damp leaf-mould and sand, cutting out all flowering-shoots, and layering the sickly-looking "grass" into the new fresh compost. This has, in most cases, been successful, though the old root may have died; the shoots layered into the new compost have revived, and grown away at once, and thus many valuable varieties have been saved.—H. W. WERUEN, *Shaldon, Triggmouth.*

Spotted and Yellow Foxglove.—The spotted varieties of the common Foxglove are very handsome. Stately of growth they are, very attractive, and being of such a robust, enduring nature, they will thrive in positions

where many hardy flowers would perish. They look well among hardy Ferns and low-growing shrubs, and if once allowed to scatter their seeds, young plants will spring up every year. The yellow kind is distinct and pleasing in colour, but not quite so robust as the spotted form. It likes a somewhat elevated position where superfluous moisture drains away in the winter.—B. FLEET.

THE KITCHEN GARDEN.

EARLY TURNIPS.

To get Turnips fit for the table in May, and even early in June, sometimes is not an easy matter in some seasons. I have read with interest the notes at various times on early Turnips, and though I had little doubt which was the best Turnip for early sowing, I thought it best to give the matter a fair trial, so last season on March 30 I sowed several lots, such as Snowball, Early White Stone, or Six-weeks, Early Munich (Fig. 1, page 224), Early Milan, White Dutch, and White Strap-leaf (Fig. 2, on this page) on the same quarter, giving all the same treatment. Extra Early Milan was fit for use on May 29, whilst the others are from ten days to a fortnight later; indeed, two of them will not be ready then, so that I strongly advise the sowing of Early Milan where early Turnips are required, sowing others at the same time to form a succession. The Turnips are much appreciated as early as they can be obtained, as there is some difficulty in keeping up the supply of good solid bulbs as spring advances, as they become soft and useless, no matter how carefully stored. For late keeping, to eke out the supply till the earlier kinds come in, there is none better than the yellow-fleshed varieties, Golden Ball being a fine winter kind. Those of the round or globe section keep much better than the flat or strap-leaved kinds. The value of Extra Early Milan is its earliness and its freedom from bolting, which are so characteristic in other early kinds. Scarcely a plant bolts on our light soil, while on heavy land it is equally good. I would draw attention to the value of plenty of moisture on light soils, as then there is no trouble in securing an early crop. For keeping I do not advise Early Milan. Those who have movable frames at liberty in the early part of the year would do well to give this variety a trial. (1.)

3911. — **Rhubarb from seed.** — The young plants should be transplanted next March. The ground ought to be trenched 2 feet deep, putting in an abundance of good manure. Set them out 3 feet apart, and keep the surface well stirred through the season. If the weather should happen to be very dry a good watering now and then will help to promote rapid and strong growth. With really good outure the plants will be strong enough to allow of pulling from the third year from seed. This must, however, be done with moderation.—J. C. B.

3912. — **Moss litter for Mushroom beds.** — I have often used this for Mushroom beds, but prefer straw litter for the purpose. If the manure is fresh mix one barrowful of loam with every five barrowful of manure, and blend the whole together. Let it be in a heap, sheltered from rain, till the heat rises, then shake over again and make up the bed firmly. The loam will prevent overheating, and the bed may be spawned as soon as the temperature is steady at 55 degs. to 60 degs.—E. H.

— This substance is not well adapted to make Mushroom beds with it; heats too violently and the heat does not last very long. I have tried it, but with little success, and sometimes the bed has borne an abundant crop of stinking Fungi. Mushrooms can sometimes be obtained, but the manure should be mixed with a portion of dry loam and turned over every day until the rank steam has been given off. There is always a danger of the mycelium of poisonous Fungi being in the peat.—J. D. E.

3951. — **Cardoons.** — Make trenches same as for Celery, only a little wider apart, as the plants will grow taller and require more earth for blanching. Plant out at once, and if you have any seeds left another row may be planted with seeds in the bottom of the trench, dropping in two or three seeds at intervals of 12 inches or 15 inches or so. Keep well sup-

plied with water, and when the plants are full grown draw the leaves together, and cover them with hay or strawbands, and earth up like Celery.—E. H.

3949. — **Unhealthy Tomatoes.** — Your description is rather vague, but no doubt the plants are affected with one or other of the Tomato diseases, and probably by that known as *Cladosporium fulvum*. You must cut away and burn the worst leaves, dust all the rest well with sulphur, ventilate the house freely, and maintain a dry atmosphere, especially when, or if, the house is closed at night; a little sulphate of ammonia will also be useful.—B. C. R.

— The plants are apparently attacked by the same disease which is so destructive to the Potatoes—*Phytophthora infestans*. I do not think it worth while trying to eradicate the disease if the plants are badly affected; it is better to burn them up, and after thoroughly cleaning the house and lime-washing the walls start again with a fresh lot of clean plants.—J. D. R.

— I should say you do not give air enough, but keep the house too close and stuffy, and perhaps give too much water. Keep the house drier by ventilation. Not much fire heat will be required now, only just a little warmth in the pipes on damp days or cold nights. Leave a little ventilation on at night.—E. H.

3969. — **Unhealthy Cucumbers.** — Too much or too little moisture at the roots will turn the Cucumbers yellow at the point. Although they are moisture-loving plants, they must not have sufficient to render them waterlogged at the roots, owing it may be perhaps to insufficient drainage. The best means of knowing whether it is owing to either of the causes named is to dig down to the bottom of the border, and if the soil is found to be in a medium condition—neither wet nor dry—the cause must be searched for elsewhere. A check may have been given to the plants through supplying them with water too cold. If it is given direct from wells, tanks, or water companies' pipes, without being aired, such conditions are not congenial to success. Overcropping will cause the points to turn yellow. It is a bad plan to overcrop the plants; far better to grow a limited number of fruit, and have them good. Very often as many as three and four fruits will show to a joint; it is not wise to leave more than one to develop. Telegraph, when true, is one of the most reliable varieties for producing a succession of well-shaped fruit. Danie's Doñanae is also another good kind. Cucumbers are easily raised from seed. Sow one seed in a 3-inch pot, placing the pot in a warm house. If the soil is moist, as it ought to be, when sowing, the seed will germinate before water is needed. Train the plants to one single stem until the desired height is attained if for a house; if for a frame, pinch out the point at the second rough leaf, to induce side shoots to form to spread over the bed.

Fig. 2.—Turnip "White Strap-leaf."

Partly decayed horse-manure is the best material for stimulating the growth of Cucumbers. A compost of three parts loam to one of manure will grow good Cucumbers. When the roots show out on the surface cover them with a similar compost. After the plants have been fruiting a month or so cover the soil an inch thick with manure only. Abundance of moisture is needed atmospherically in the house, not only for the benefit of the Cucumbers, but for the prevention of insect pests. An arid atmosphere will encourage the spread of red-spider.

If the leaves become infested with this insidious pest they are bad to cleanse from it. Syringing the plants every afternoon about four when the weather is fine. In regulating the shoots keep them rather thin; it is a mistake to overcrowd the plants. Pinch out the point of every shoot above the second leaf, and remove the fruit above that leaf, allowing that below to develop. Another shoot will spring from the uppermost joint. When this has grown two points serve it in the same way.—S. P.

HOUSE & WINDOW GARDENING.

3931. — **Insect pests.** — The brown spots on window curtains, cushions, &c., are most probably caused by bluebeetles. An "unusually large quantity" possibly is not present, as half-a-dozen will make a window filthy in a day or two. The only remedy I have ever known successful is to grow strongly-scented Geraniums in the room. Peppermint Geranium, if not objected to, is the best. Fly-papers can, of course, be used, and any eggs that may be found should be at once destroyed.—M. A. W.

Mossy Saxifrage as a window flower. — When at a friend's house recently I was charmed to see a departure from the orthodox type of window-box. It was filled with the Mossy Saxifrage (*S. hypnoides*), and the flower-spangled growth hung over the sides. The plant has quite established itself, and the centre was occupied with Mrs. Sinkins Pink in full bloom. It would be easy to get many pretty effects from window-boxes if suitable things were selected and not grown in a formal way. The Pink looks remarkably well thus used, and keeps in bloom some time, the effect of its flowers against those of a Blue Bell-flower being most pleasing. *C. fragilis*, *C. gargaricus*, and many of the other trailing or creeping kinds could be used. It would not be necessary to remove the Saxifrage for summer. Its mossy growth is always welcome.—C. T.

RULES FOR CORRESPONDENTS.

Questions. — *Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender will promptly be added to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent in press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.*

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by adding, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

- 3925. — **Budding Roses.** — Would anyone kindly give me a few hints on budding Roses? — S. H. BAKER.
- 3926. — **Plants for Sheffield.** — What plants are likely to thrive best in the town of Sheffield? — F. T. W.
- 3927. — **Soil for Petunias.** — Would someone kindly tell me the best soil in which to pot Petunias? — LAURIE.
- 3928. — **Peach-tree branch withering.** — What is the reason of a branch of a Peach-tree withering? It is in a cool-house. — H. G. W. G.
- 3929. — **Mackaya Bella.** — A friend has given me a plant labeled Mackaya Bella. Will someone please advise me as to treatment, &c. — Novice, Nonmouthshire.
- 3930. — **Early Potatoes.** — I shall be obliged if any of your correspondents will give me directions for sowing seed of the very early Potatoes (Ashleaf Kidney) for next year? — STAMPS.
- 3931. — **Creepers for walls.** — Would someone kindly advise me what creepers to plant for north-east and south-west aspects? Also what plants to put in boxes for those aspects? — G. CUBERT.
- 3932. — **India-rubber-plant.** — The leaves of my plant all died off in the winter. There are now seven or eight young shoots on the old stem. Should any of these shoots be removed? If so, could I strike them in an ordinary greenhouse? — L. Q.
- 3933. — **Tuberous Begonias.** — I have several of these in pots, which I propose to transfer to an outdoor bed in about ten days' time. I shall be glad of any advice as to treatment, especially as to what should be done to them after they have bloomed? — WINDMOR HILL.

3934.—**Plumbago capensis**.—I have a Plumbago capensis about 2 feet high, well branched, and nice and green, but the leaves are very small. It is in a 7-inch pot. There is no sign of it flowering. Will Clay's Fertiliser be useful to it? And a few hints as to its treatment, soil, &c., will oblige?—LATAIS.

3935.—**Flowering shrubs**.—Will anyone kindly let me know the names of four or five good hardy flowering shrubs (worth growing near the front of my house), height about 12 feet or 14 feet, and evergreen if possible? Also best soil to grow them in, and best time to plant? Locality, Ireland.—ENGLAND.

3936.—**Planting Rhododendrons**.—Will any person please let me know when is the best time to plant Rhododendrons, and shall I likely be likely to grow them in a good loam (limestone land)? I have been told that they will not grow in this soil—that I must prepare a peat bed for them. Is this so?—ENGLAND.

3937.—**Climbing Peas**.—Being down in the country the other day, I had my attention drawn to some Peas, which had proved to save the trouble of staking them, and I was told that they would bear just as well as if they had been allowed to climb. Being about to stake some Peas, I should like to have an opinion on the subject?—J. H. GRAY.

3938.—**Marchal Niel Rose**.—Last autumn I bought one of these Roses having two stems, each about 10 ft. long, and put in a cool lean-to house, planted in the border. Has this year borne seventeen blooms. What is the proper treatment now? Should it be let alone or cut back? If the latter, how and when? Any information will be grateful to a—CONSTANT READER.

3939.—**Manure for Cockscombs**.—Will someone kindly give me a little idea of what quantity of manure to use for Cockscombs? They are in 6-inch pots, with combs 4 inches over, and I should like to get them for show on the 20th of next month. I also have some nitrate. Would that be of any use to them? I do not know how to use it. Answer to this would oblige.—AMATEUR.

4000.—**Zonal Pelargoniums**.—I have some nice rooted cuttings of above in pots buried in ashes out-of-doors. I have planted in pots, and in a garden bushy plants, as I wish them to flower in the winter. In my garden. Will some kind friend advise me as to treatment, what manure they require, etc., to produce fine flowers? Also some good varieties.—NORTH, Monthshire.

4001.—**Unsatisfactory Cucumbers**.—In January last I planted several houses of Cucumbers, "Sutton's Improved," they fruited very well for a little while, now they seem to have gone off, scarcely producing any fruit; as they make their breaks the fruits go yellow and die. I have pulled some of the plants out and find their roots knotted. What is the cause of their being knotted, and is this the cause of the mischief?—E. B.

4002.—**Paraffin-oil and water for plants**.—Will someone kindly tell me what quantities each of paraffin-oil and water would be safe to apply to dip the plants into from a small greenhouse to remove green-fly and other insects from such things as the Aбуdions, Chrysanthemums, Fuchsias, and Nicotianas? Also state if the same would be either destructive or injurious to the flowers and foliage?—M. Y. M.

4003.—**Blight on Apple-trees**.—I should feel much obliged if anyone will kindly let me know what is to be done with Apple-trees which are covered with a white stuff similar to mildew in appearance, but underneath the bark is broken and a gum-like substance oozes out. I am told it is "American blight," and that it will eventually kill the trees. Is this so? The soil is gravelly. The trees have not been pruned for some time.—A CONSTANT READER.

4004.—**Orchids in a greenhouse**.—I shall esteem it a favour if anyone will let me know if I can grow Orchids in a greenhouse where the temperature is never under 45 degs and seldom above 75 degs to 80 degs? If so, if someone will kindly mention a few varieties, not very costly, suitable for cultivation by a beginner? The house is divided into two portions, each 16 feet long by 12 feet broad, and outside air is considerably cooler than the other.—GROUPELTON.

4005.—**White Banksian Rose**.—I have a specimen of this Rose planted this year since it has made vigorous growth from the first, and now covers the space with an abundance of short lateral growth. It has never bloomed, but this year it has produced flower-buds, but instead of being in clusters, they are formed singly, and few and far between, and none seem likely to develop, but drop off. I have never pruned it, having been advised not to do so. Should it be pruned, and if so, how and when?—E. L.

4006.—**Tomatoes not setting fruit**.—Will anyone kindly inform me as to the reason of my Tomato-plants not setting fruit after the flowers have fully developed and bloomed? They are being grown in a spanned greenhouse, which gets the sun upon it all day. I planted them out in April, and they have now grown about 4 feet in height. They look very healthy and strong. I have also thinned out the foliage by keeping back all side shoots, and also cutting away some of the leaves, and new water the foliage, but give them plenty of water at the roots. Am I right in treating them in this way?—X. Y. Z.

4007.—**A Plague of rats**.—I live in a detached country house where I have a garden. Rats are a perfect plague; in winter they infest the house, devouring stored fruit, and potatoes of all kinds. In summer they dig up Potatoes, devour Cabbages and Strawberries. I have kept cats, but they prefer rabbit to rat hunting. I fear to use poison about the house on account of danger of putrifying carcasses being left under the floors. We have no professional rat-catchers in Ireland. Will anyone kindly advise on the subject, giving experience as to poison, &c. I may say that I have used various traps, but the vermin avoid them either one or two have been caught.—B. W. F.

4008.—**Rose Gloire de Dijon, &c.**—I have a large Gloire de Dijon Rose, two of the shoots of which forced their way some 20 inches to the ground, and they though I pruned it closely last spring. It has since the first blooms were out now grown so rampantly that it has completely covered the glass of half the house (a lean-to, 28 feet long), and I shall be glad for advice how to manage it? Am I to cut it in closely, or let the shoots remain?

It was covered with its lovely blossoms. I cut hundreds off it. It is planted outside, and I have frequently given doses of liquid-manure made from horse-droppings. I syringed it inside frequently with soap-suds from the laundry, and it is quite free from green-fly, and appears in splendid health. Also please say how I am to treat a Marchal Niel Rose in a pot after flowering? There were eleven good blooms on a small plant in an 8-inch pot. Should I repeat it now or cut it back? Any advice will be gratefully received. I manage the greenhouse myself, potting, etc. I have other Roses after flowering, and have put them (they are in pots) outdoors. Should I report them?—A. M. G.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4009.—**Budding (H. Shepherd)**.—At this season it would be a failure, I should say, because the bark would not run well, and without it does so you cannot hope for success. You must wait until we get some more wet and favourable weather.—J. J.

4010.—**Pins-ouss (Charles Pope)**.—I have named them and returned them, as you desired, by rail to Exeter. Most of them are apparently *Pinus*, great American species, or Californian; but I do not find the Great Wellingtonia giganteum amongst them.—J. J.

4011.—**Peas, early (George Pile)**.—I am very much obliged for the nice dish of Peas sent by Percels Post. They were certainly a very fine sample, and I should like them for William L. They were quite right sent in the pots. It gave me a better opportunity of judging them.—J. J.

4012.—**Paraguay Tea**.—C. Jenkins asks if this can be obtained in England, and from what plant it is obtained? Yerba, as it is called, is prepared from the leaves of an evergreen tree of Southern Brazil, called *Ilex paraguayensis*, and it is largely used in South America. I do not know if it can be procured in this country, but I do not think it can.—J. J.

4013.—**Madevallian (T. H. B.)**.—The two blooms sent are magnificent flowers of *M. Veitchii*, which is yet the grandest of all this family. When I knew Mr. Bateson, who was so fond of this family, and he used to describe them to me in such glowing colours, this, the finest of all, was unknown; they are two distinct forms, and both very fine, but neither of them can be called *Veitchii grandiflora*.—M. B.

4014.—**Soil for Orypidium Insigne**.—G. Rathwood complains that I should have recommended charcoal and living Sphagnum for this plant, as I have done on page 179. Upon looking at the page indicated, I find it is not my article at all. I quite agree with "G. E." that half good light truly loam suits this plant well. The plants should have been posted before this, if it was required.—M. B.

4015.—**Soil for Gesneras (G. Helmsley)**.—Use tuff-peat, fibrous manure, good leaf-mould, and sharp sand in about equal parts, drain well and water freely, but do not syringe at any time. I like to maintain a good moist atmosphere, but totally object to syringing overhead, on account of the woolly nature of their foliage. You may give the plants another shift, as you say the tubers were started in the middle of April.—J. J.

4016.—**Luffa sponges (C. Jenkins)**.—These are sold by the chandler, and are the internal fibre of a Gourd called *Luffa sycylifera*. The plant is really a native of Egypt, but it is cultivated in many parts. They are sometimes sold as West Indian bean sponges, where they are largely grown, and I have grown the plant at home, and used it for the same purpose. I find, however, that the plant, when grown at home, has softer fibres, which does not last so well.—J. J.

4017.—**Miltonia vexillaria**.—George Thompson sends, in No. 1, a very good variety of this Orchid; it is a plant that naturally gets a great deal of wet and a very agreeable temperature, and although not found until about 1859, the plant has a wide distribution in New Granada, so much so that reasonable hopes remain that there are yet more new species to find in various parts of the mountainous regions of New Granada. No. 2 is very like the form called *vaucoulesii*, with the sepals and petals pale rose, and the lip white.—M. B.

4018.—**Palms in pots and tubs (J. Cradock)**.—These plants should be kept in their pots as long as possible. Indeed, I cannot understand why it is that English gardeners appear to put specimen Palms into pots of such large size, whilst on the Continent the opposite case is maintained, and with much better effect. Drain well, and set them firmly, and in the spring or early summer they should have the old surface soil taken away and renewed, using for this purpose old, but not spent, cow-manure, and water the plants freely.—J. J.

4019.—**Lælia purpurata**.—J. Foster sends me flowers of this species, which are they not beautiful? and have no doubt when seen on the plants they were very beautiful; but as these flowers had been out two days when I got them, and moreover, as they were put into a perfectly dry wooden box, which had sucked the life out of them, they appeared to have narrow, ill-formed sepals and petals, and so much of their beauty was gone. I have had a lot of flowers of this species sent me this season, and yours, although good, do not exhibit anything above the average.—J. J.

4020.—**Lælia Cattleya**.—J. Johnson asks my opinion respecting this system of naming, saying he does not like it; I can quite agree with him. It is all very well now in the first instance to name such nearly allied genera, but if this sort of thing is persisted in we shall not only be in trouble in pronouncing the names in the third and fourth generation of crosses. These names may be all very well to have the plants registered under, but they should not be used as common garden names. What, for instance, would look more ridiculous than *Lælia Cattleya Susan Brown*, and why such an absurd Latin name?—M. B.

4021.—**Madevallia finestrata (T. Jackson)**.—This is a very fine flower, I have not known this species, but well I had not seen a flower for a long time. When I did know it, I found the plant to do well at the warm end of the Odontoglossum-house; but liked the Cattleya-

house in the winter. There is another species belonging to the same set of plants called *Dayaum*, and to these two little plants the unpronounceable name of *Cryptophloeanthus* has been given, and which I should imagine was given in order to make the study of Orchids easy and popular.—H. B.

4022.—**Bonia megastigma (J. Earl)**.—If your plant has done blooming I would cut it back rather hard, putting it into shade, and not until it has been cut do not set in the open at any time, for it does not thrive so treated. For soil use good brown peat, chopped up, mixed with sand, and be sure and drain well. Then even if you should give too much water at any one time it will drain away. Stop the young shoots to make the plant grow uniformly and to balance. One of the results of this species is that it runs up thin and tall unless proper attention is given to this (the plant which should be grown by everyone for the sake of its grateful perfume).—J. J.

4023.—**Tabouros Begonias (B. Jones)**.—Well, this query just indicates the exact state of some of my own things for I have a double yellow, and some others which have not started yet; but I suppose they will do so, as upon looking at them, which I have just done, I find they are alive and sound, whilst my others are growing nicely, some showing flower; but I am rather later than last year, for my Begonia had then begun to flower in the first week in June, and the same plants continued gay until the end of October, which filled my house with beautiful flowers for five or six weeks. You may, if you do not keep on hoping for them to break away, which, while there is life, can be expected. As for myself, if I had the convenience of a little fire-heat, I should give it them. Named kinds are all very well; but for an amateur, the colours are all that is necessary. See Mr. Laing's and Mr. Cannell's; these are the two best collections in the country, undoubtedly.—J. J.

4024.—**Maggots on Parsnip (J. F.)**.—The Parsnips are no doubt attacked by the grub of the Celerly-fly, which also attacks Parsnips. They will not injure the roots, except that by despoiling the foliage they also injure indirectly the roots, which would not come to perfection if there were no leaves. Pinching the hillocks where the grubs are, or picking off and burning the leaves are the only remedies. Scattering soot, quinine, or finely powdered soot over the leaves on a dowy morning or after rain is useful. When the crop is pulled up, all affected leaves should be burnt, and the ground deeply trenched, taking care that the surface soil is put at the bottom of the trench, as the chrysalides may be found 2 inches or 3 inches below the surface, and being deeply buried, the flies will not be able to escape.—G. S. B.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 87, Southampton-street, Strand, London, W.C.

Names of plants.—A. W.—1, *Blechnum occidentale*; 2, *Asplenium Fabianum*; 3, *Campylopusium angustifolium*; 4, *Hymenophyllum dilatatum*.—J. J. (The plants are not named.)—Send again when in flower or fruit. *Veronica*—cannot name from such small, miserable specimens.—Britain.—1, *Dryas octopetala*; 2, *Rhinanthus cristata-galli*; 3, *Plantago Coronopus*; 4, *Hieracium glabra*.—Canon.—Cannot distinguish it.—Fern.—1, *Platyloca Brownii*; 2, *Leptogramme tatarica*; 3, *Balenium rotundifolium*; 4, *Lomaria discolor*; 5, *Lomaria speciosa*.—J. Childs.—1, Fair form of *Lælia purpurata*; 2, *Cattleya Mossii*; 3, *Cattleya speciosa*; 4, *Odontoglossum albiflorum*.—J. Everett.—Send again when in flower.—H. Waller.—1, *Papever dubium*; 2, *Crocus deturcicus*; 3, *Prunus Pallasii*; 4, *Orchis mascula*.—G. C.—*Orchis foliosa*; 2, *Orypidium arcticum*; 3, *Orypidium pubescens*; 4, *Saxifraga longifolia*; 5, *Dielisya eximia*.—J. Gelsleri.—Specimens too poor to name.—Zelding.—*Oraxella (Kalosantes) cocconia* apparently; but if you could send a head of *Bowers* we should be quite certain of the matter.—Mr. M. Briggs.—We cannot name a seedling Begonia. Call it what you like. We should say that it will probably flower this summer.—J. P.—*Lonocera (Honey-suckle) speciosa*; but spelled by being packed in wet moss.—G. J. Creny.—We do not recognize the plant from dried-up specimen sent.—Hayford.—The iris flowers were completely spoiled by being packed in dry rotten-wood. This is the worst of all packing material when allowed to touch the blossoms, and the feet has been pointed out many times in GARDENING ILLUSTRATED. Please send fresher specimens, and they should be better packed.—Mrs. Craig.—Lilium giganteum.—T. M.—Hayford.—Plant *Sedum Fernaldii*. Strawberry crushed up.—Trosack.—Numbers detached. Cannot name.—Yielding.—*Veronica subciliata*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender. A. M. G.—The Cherry-trees are evidently in bad health, probably from age, and the roots getting down into unsuitable soil. Please state nature of subsoil, &c.

POULTRY AND RABBITS.

4025.—**An incubator**.—Will someone kindly tell me the best lamp to use to heat a home-made incubator to raise chickens in? The boiler is 23 inches by 23 inches long, and I should like to have the best 8 inch boiler plates high only. Any information will be gratefully and thankfully received.—GARDNER'S WIFE.

4026.—**Unhealthy fowl**.—I should be glad to know of a cure for a complaint among fowls, in which the body becomes covered with bladders? Also the name? The fowl in question has been well fed.—E. M. B.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of new and rare flowers and good fruit and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

A FREE USE OF MANURE.

Those private gardeners who have only previously seen but little of what is going on in the market gardens and farms round London and other large towns are invariably impressed with their first glimpse into the ways of these market men. Especially are they surprised at the quality and quantity of manure that is used. As a rule, private gardeners fail to get enough solid manure, and in very many instances have to be content principally with what has previously done duty as hot-bed material. Very poor stuff the latter is, or little better than a mass of humus, and as such ought always to be supplemented with fairly liberal supplies of chemical manures, that most generally needed being potash in some form. To all appearance market growers apply their cheaply-obtained and really good animal manure—the principal fertilising properties not being either washed out by rains or dissipated by undue fermentation—at the rate of not less than 30 tons, and not unfrequently nearer 40 tons, to the acre. The ground being in a good condition for receiving this, it both can and does produce enormous crops in close and rapid succession. Good stable manure, such as can be obtained in the neighbourhood of large towns, and also any from a mixed farmyard, more especially where the fattening of beasts is going on, is as near perfect as can be mentioned. In this case it would appear next to impossible to overdo the ground with this in a semi-decayed state, always provided the cropping is close and heavy. It is very different with the rotten stuff that has to do duty in very many private gardens. This contains but few constituents of a plant-sustaining nature other than moisture, and which humus both holds and absorbs from the atmosphere. In the course of a few years this kind of manure sours soils, especially those of a clayey nature, and this can best be corrected by a dressing of lime instead of manure applied at the rate of 2 bushels per square rod. The lime most to be preferred is that obtained from the magnesia limestone rock, and this ought to be applied direct from the kiln. It can be most simply slaked by being laid in small heaps and covered with soil for a few days, and should then be spread over the surface of the previously dug ground and forked in. The effect of this dressing on manure-sick ground is almost magical. It has the effect of liberating food previously locked up, and enters into combinations with other constituents required for the invigoration and sustenance of vegetable life generally. It was not, however, my original intention to discuss the

mixing manure freely with both spits, while if the nature of the ground renders trenching impossible, increase the depth of surface-soil by means of additions of compost in which strong loam and manures figure largely. In my case Globe Artichokes are of such importance that I would deny any other crops solid manure in order to let the former have plenty both mixed with the soil and in the form of a mulching. Rhubarb is not nearly of such importance, but pays well for liberal treatment. Onions, if wanted of large size, must have plenty of solid manure in the soil in addition to soot and other manurial dressings, and even if medium-sized to small roots are preferred, it is advisable to make the ground rich, firmness of soil and thick creeping doing the rest. Soot, in addition to being a good fertiliser, is also to a certain extent a preventive of Onion-grub. It pays to well fork in half-a-bushel to the red early end apply another somewhat lighter surface-dressing just prior to sowing the seed. It is an old custom to sow Onions in succession to Celery, the latter being supposed to leave the ground in excellent condition for the reception of the former. Such may be the case in some few instances, but, as a rule,

CELERY exhausts all the manure placed in the trenches, and the apparently finely divided state of the surface of the ground when levelled is altogether misleading. The surface may be perfectly fine, and just underneath patches of soil closely run together, wet and cold, be found. It answers my purpose to devote ground previously cleared of early and mid-season Celery to Onions, but advantage is taken of a frosty morning to wheel on a good dressing of manure, rough digging following as soon as practicable. Thus treated the soil breaks down admirably at sowing time, invariably producing a good crop of medium-sized, firm Onions, and when the latter are cleared off very little further preparation is needed for spring Cabbage. If Carrots, Beet, Salsafy, and such like were to follow Celery, I would yet advise digging the ground deeply after the levelling has taken place, no animal manure being given however. Contact with the latter and also masses of wet trampled soil hurried well below the surface by the levelling process cause tap-roots to fork badly. These, therefore, should have a finely-divided deep root-run, and if solid manure is applied it must be buried not less than a foot deep. It is a mistake to be too stingy with manure as far as Potatoes are concerned. Doubtless market gardeners somewhat over-do their dressings, contact with so much strong manure having the effect of impairing the quality of the crops. If such is not the case, how else are we to account for the bad quality of the bulk of market Potatoes as grown in the vicinity of large towns? If good solid manure is applied at the rate of 30 tons to the acre, this being dug in now where the land is of a heavy nature and not distributed market farmers' fashion along the drills at planting time, the Potatoes will get the full benefit of this and leave the ground in splendid order for any members of the Brassica family or Strawberry. Gardeners having nothing but poor rotten manure to wheel on to their

POTATO ground ought to supplement this at or near planting time with either soot, guano, or superphosphate and kemit. Well-decayed garden refuse to every five loads of which one load of fresh lime has for some time previous been well mixed, is one of the best manurial dressings that can be applied by way of a change to Potato ground. Peas, runner and Broad Beans must have plenty of manure under them, or they are liable to fail badly in hot, dry weather. The manure dug in ought also to be only partially decayed, as I have repeatedly found that where old hotbed or very rotten manure has been used, the former especially has been badly attacked at the roots by eelworms. When once the letter make their home in the roots these become greatly swollen, and both root-action and top-growth are quickly perished. Wood ashes mixed with the manure and very lightly sown with the seed is a preventive of insect attack at the roots, and also acts as a powerful fertiliser. Sown too freely with the seed it is liable to cause the letter to decay, and the soil in the drill ought only to be just whitened by dry wood-ashes at sowing time. Kidney Beans will thrive well for a short time on unmanured ground, and produce heavy crops if they succeed a crop for which manure was freely dug in.

CARLIFLOWERS revel in a rich root-run, the strong fresh manure dug or ploughed in by market growers suiting them well. To have them extra fine, or say fit for exhibition, manure should be freely dug in and liquid manure given in large quantities when the hearts are forming. If Brussels Sprouts are given good room and a moderately firm root-run, there is not much likelihood of too much manure being applied at the roots, and the same remarks apply to Borecole generally. Broccoli, Chon de Burghley, and Savoys I prefer to plant in succession to Leeks, Strawberries, or any other crop for which manure was freely used, a moderately rich, yet firm root-run best suiting this class of winter vegetables. H.

THE DROUGHT.

THE present long-protracted drought has sorely taxed the resources of all gardeners, but doubtless many valuable lessons will be learnt that will aid many to combat future visitations of the same kind, and doubtless if we had such prolonged droughts more frequently there would be more deep cultivation done in the winter, for the difference of the look of crops on really well worked and manured land with others only shallow cultivated, in spring, is most marked, for as long as food and moisture is beneath a crop, the roots will go down and find it, and the tops will indicate that the crop is making progress. But when the land is cropped and drought is upon us, the best antidote I have found is the hoe and rake, frequently used to pulverise the surface and work it down into a dust-like surface—for the fierce rays of the sun that extract the moisture from the surface at a rapid pace, leaving it apparently drier than before, appear to have little power to extract the moisture from a covering of 2 inches or 3 inches of dust on the surface—and it is surprising how crops have held out against the long

drought when the hoe has been kept going amongst them. Mulching is a great aid to fruit-trees, bushes, and Strawberry beds, rows of Peas, Beans, &c., but it can hardly be extended to all crops that need it, and the simplest and best remedy is to hoe, even if not a weed is visible. Such is my experience. J. G. H.

GARDEN WORK.

Conservatory.

Jasmines are always appreciated everywhere, and where there are borders in the conservatory for climbers, one or two Jasmines should be planted. They will grow and flower freely in loam, peat, and sand, or in loam and leaf-mould and sand. To flower well they must have light enough to ripen the wood. They do very well trained up a pillar or against a wall, or may be trained over an arch. J. gracillimum and grandiflorum are good varieties. I have grown them in pots, but they are so much better planted out that an effort should be made to open up a border for them. To go a little further into the question of providing climbing plants for the conservatory, Mandevilla suaveolens has white, very good flowers, which are borne in large clusters in summer. Let it ramble up to the roof near the open lights. Plumbago capensis, Rhysochloa jasminoides, Solanum jasminoides, Solysia heterophylla (pretty blue-flowered twiner), Swainsonia galathea (the pea-shaped flower are useful for cutting, should be planted in peat and loam in a light position; does well trained to a pillar. One of the very best wall or pillar plants is Lucois gratissima. The flowers are sweet-scented, and are borne in large clusters at the end of the current year's shoots. Habrochloa elegans and others are bright and showy, and when planted out are seldom without blossom; but autumn and winter is the natural season of blooming. The above are mostly of moderate growth, and will do in comparatively small houses. For large conservatories Passiflora, Tecomania, Bignonia, and Tecoma will give a nice variety; but there are many plants adapted for covering walls and pillars and to provide quantities of flowers for cutting besides those named. Fuchsia, Ivy-leaved and other "Geraniums" grow very rapidly when planted out. Roses, again, are very charming under glass, especially the Tea and Noisettes, and a plant or two of Tropaeolum Fishall planted now and trained wherever there is room will produce much brightness in winter. Greenhouse Rhododendrons have pretty well completed their growth. Large plants of such kinds as Countess of Haddington, Duchess of Bureghill, and others of similar habit of growth, including Edgeworth, are very beautiful, and the flowers very desirable for cutting. So soon as the young growth is a little firm set the plants outside on a cool seat to ripen the wood. When repotting is necessary use only good peat and sand, and pot firmly. In rearranging this house, and the others if it does the better, a few specimens may be brought from the stove to make room there, and, at the same time, add a fresh feature to the conservatory. If Camellias are placed outside let them have a shady spot where the midday sun cannot reach them, and they must be placed on a bed of ashes to keep the worms out of the pots. This is a very important matter in placing greenhouse plants outside in summer.

Stove.

Vines are very useful for summer blooming. They make very useful exhibition plants when well grown; must be freely pinched during growth to get a bushy habit should be potted in rather porous materials, such as peat, leaf-mould, a few rough pieces of old turf, and plenty of sand. The growth is free and robust in such compost, and stimulants may be freely given when the plants show flower, without making the soil sour. The old plants should not be kept too long, as a young plant quickly grown will make a specimen; indeed, there is a good deal of room for this clinging to old specimen plants, both in the stove and in the greenhouse; younger plants would be far more effective than many of the old specimens still retained in many gardens. Cuttings of most of the usual plants grown can be struck at home; the only plants that need be purchased are new things. Slow-growing plants, such as Rondeletia speciosa, Ixora, Francosera, most of which are beautiful winter-flowering subjects, are a long time getting out of the soil. The dwarf bush (Cero dendrons, such as C. fallax, squarata, &c.) are very bright when in blossom, and are easily increased by cuttings. After flowering the plants may be cut back. Among berry-bearing plants Rivina humilis makes a pretty little table-plant in winter, is easily raised from seeds or cuttings. It generally drops its berries, and they come up all over the house in borders and pots. Cuttings of young plants of Geranium should be given in a close, warm pit; they do very well in the hot-bed. A small, low house, with lead or tan beds therein, is very suitable for this class of plants, and it is desirable, as far as possible, to regroup subjects now to make the most of the time and opportunity for growth. If there are mealy-bug and other insects in the collection, not for an instant should these be lost sight of, or there will be endless work by-and-by. Something may be done by syringing with insecticides to check their progress for a time, but the sooner in the heat, the more sure where a determined effort is being made to clear them out.

Winter-flowering Begonias.

Those who have not got a collection of these should buy small plants now and grow them on. They are charming things in the stove, and even in a warm greenhouse, in winter; very easy to grow and propagate, and cheap if bought in small quantities. When they begin to grow freely pinch the leaders to induce a bushy habit. Loam and leaf-mould in equal parts, lightened with sharp sand, will grow the Begonia family very well. The following half-dozen are among the most useful: Insignis, aconitifolia, semperflorens, giganta, oermilines, mansueti, nitida, alba, and fuchsoides. The last-named, though an old sort, is very graceful. It is best to propagate young-stock annually early in February, and throw out all the old plants.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

Ferns and Mosses.

This is a good season for buying in new stock. It is quite as well to purchase small plants of any particular variety and grow on, and the money goes further. The variety of Ferns is almost endless, and every year sees something new introduced. I am not going to give a list of Ferns for several reasons, for it would take up a good deal of space; and, secondly, trade Fern-growers are now scattered pretty well all over the country, and a visit to a nursery is easily made. The number of Adiantums is now simply marvellous, and a collection of Maiden-hair would be very interesting. To name only a dozen that everybody should grow who has a hothouse, we will take Adiantum Farleyense as one of the handsomest Ferns grown, then would come A. Williami (Golden Maiden-hair), A. gracillimum, A. decorum, A. cucullatum, and its variety elegans (A. assimile, a very pretty little Fern), Conium latum, A. Paucifl., A. Anatum, A. trapeziforme, and setulatum. This will give a number of distinct varieties at a comparatively small cost.

Pits and Frames.

These will be filling up now, or some of them, with winter-flowering plants. When young and tender, just removed from stove or forcing-house, keep the frames closed for a time and shade when the sun is bright. When the plants get accustomed to the position and commoner to grow a little, air may be given, and then less shade will be required as the growth gets harder.

Window Gardening.

Window-boxes will now be very bright, and as it is the custom to fill the box quite full of plants, weak stimulants may soon be given. Plants outside windows require a good deal of water. Foliole Begonias, of which few may be taken at a distance, and among the green-tinted Ferns at this season; they may be kept through the winter in a warm room if not overwatered, and it is best not to overpot. The Mesochoranthemum family are very beautiful now in sunny windows. I have lately seen a few of them about. Perhaps this denotes a revival.

Outdoor Garden.

The one compensation of the season is the absence of weeds where the hoe has been used at all; but I fancy most of us would rather weed than water, and so long as the water in a stream is present character there must be a good deal of water used. Happy are those gardeners who have plenty of manure for mulching purposes; these alone are masters of the situation. Burnt earth is found very useful for mulching purposes; an Inch or so spread over the surface of a bed or border effectually checks evaporation, and the plants do well and the birds do not scratch it about as they do manure or peat-moss-fibre. One of the brightest bits of colour at the present moment are a mass of Red and Yellow Iceland Poppies, where one may not come again for some time. Other plants which are standing the drought well without water are Rocket, Potentillas, Campanulas, including Canterbury Bells. I have a mass of these growing for seeds, and everybody admires them. Perennial Gilliflowers again are making a splendid show, and Antirrhinum and Snapdragon seem to enjoy the drought and the hot sunshine. Mulch Stocks, Asters, Zinnias, and other Drummonds; these will come out if mulched with good manure and watered occasionally. If Asters are neglected the flowers will be small. Hollyhocks and Dahlias must be well supported, and Phloxes, unless well cared for, will be very poor things. Pinks should be well watered to get the grass into condition for taking cuttings. There will soon be a feast of Geraniums; see that all are staked up carefully, and a layer of good soil spread over the beds will be a great help to the blossoms, and will be ready for layering by-and-by. Newly-planted trees and shrubs must have water till rain comes if they are to be kept alive.

Fruit Garden.

This is not going to be the ill-fortune season most of us expected. Bush fruits and Raspberries are very small where left to themselves. Mulch and water might have altered matters, but in many cases this has not been done. Strawberries on good land well manured are fairly good. Plums (excepting the King of the Heart) are not so good as they are falling fast through drought, and in a good many crebber insects are having a good time. There will have to be a general awakening among fruit-growers before the sunshine can be of any benefit. Insects must be destroyed by spraying in summer and by dressing the trees in winter. Drought must be counteracted by the use of mulch and water, and then the sunshine, instead of being a hindrance, will be a help. I admit I have said something of this kind before, but the soil can only be driven home by repeated taps with the hammer. Shorten back the breastwood of Plum on walls to four leaves; lay in as much young wood as there is room for, and where the trees have been neglected, and have become infested with insects, pick off some of the worst of the curled-up leaves and attack the insects with the usual remedies, the best and simplest being soft-soap, 2 oz. to the gallon, with 1 quart of Tobacco. Use up to 4 gallons of the soap-water. Washes of all kinds have more effect if used warm. Melons must have water enough to keep the leaves healthy, and they will take a good deal during this scorching weather; glycol stimulates as soon as the crop is set and swelling freely. Melons may yet be planted on genial hot-beds. If Peaches are watered heavily after the fruit begins to ripen the flavour will suffer.

Vegetable Garden.

Seeds of Cardoons may be planted in well-mannered trenches in pot-beds—three seeds or so in a patch—12 inches to 15 inches apart; if all the seeds grow remove all but one. Plant Turnip-rooted Celery (Celeriac) in rows on the surface of well-manured land, the rows to be 18 inches apart and 9 inches apart in the rows; water freely and shade with branches till the plants get well established or till rain comes in sufficient quantity to moisten all the ground. Sow the seeds of Turnip-rooted Celery in a trench. Scotch's Red Onion is a good variety, and those who like yellow seeded Turnips may sow Orange Jolly. Turnips in a dry season should be sown on land that has been prepared in a hot bed or two to get settled and for the moisture to come up from below. Draw the drills rather deep than shallow, and soak with liquid-manure. If in the meantime rain falls the liquid-manure may be omitted, a little watered manure being sown in the drills instead. Really good

Lettuce and Cauliflowers will be in demand now, and so only be obtained by good cuttings and a free use of water and mulch. Plant and sow for succession on good land. North borders will be useful now. Make up Mushroom-beds in a cool, shady spot, such as the north side of a lofty wall; a good way of doing this is to knock up a rough kind of pit with boards, and cover with old shingles or something of the kind; hurdles slatted with straw will do. We want to keep in the moisture and keep out the scorched atmosphere. Let Tomatoes have all the attention required. Plants trained to one stem must have all side shoots removed when small. Better prick leaders when four or five trusses of fruit are set. E. HOSBAY.

Work in the Town Garden.

Window-boxes ought to be looking gay now. For a wonder those on a north or shady aspect are doing best now, as where exposed to the full glare of the sun the plants soon get burnt up. If not very regularly watered, and in any case the flowers quickly fade. Under such circumstances a hind or shading of some kind would be advisable. There are different ways of planting window-boxes; but, as a rule, I find it best to put in plants grown in pots in some close-fitting boxes placed in the bed kept moist. Where there is a reserve of plants to fall back upon this is decidedly the best plan, as they can be changed or the arrangement altered so often as necessary, while, should one go wrong in any way, or go out of flower, it can be replaced in a moment. The pots being surrounded with a moist and non-conducting material, the plants grow almost as well as if planted out in a bed of soil, and only a little stimulus occasionally is necessary. Even if water at the root is not necessary, the overhead shower with a fine-robed can or syring morning and evening must not be omitted in such weather as this; it refreshes the plants wonderfully, especially when they are exposed to the sun for the greater part of the day. Pelargoniums of the large-flowering section are making a fine display just now. As a rule, shade is not necessary for these plants, and, indeed, they do better without it; but in very hot weather, such as this, a light protection from the sun's rays during the middle of the day will prolong the beauty of the flowers considerably. These are capital town plants, flowering freely even in pots, though the growth is not so sturdy and vigorous as that of the country grown plants seen in the markets and shops; but when planted out-of-doors they thrive amazingly, quickly making quite large bushes, and flowering more or less continuously throughout the whole summer. As the plants in pots go out of flower they should be turned out into the open air, standing them on ashes in a sunny spot and giving very little water. When the wood is thoroughly hard cut the plants down severely, and put in the tops for cuttings. The old stumps should be shaken out and replaced into small pots as soon as they "break" again, and may then be grown on into large plants. Watering occupies the greater part of the time now; everything, and pot-plants in particular, must have water, and plenty of it, or they will not prosper. Dahlias, Verbenas, Begonias, Fuchsias, and Calceolarias especially require abundance of moisture; but "Geraniums" and Petunias flower better if moderately dry. B. O. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from June 24th to July 1st.

Shifted seedling Cyclamens into 5-inch pots; these plants, with Onocrotis and Primulas, are now in low pits and frames, where the treatment they require can be given. Shifted on Chrysanthemum. Of course, the unsorted specimen plants have been potted several weeks; but Chrysanthemum are treated in various ways. A considerable number of my plants have been cut down, and then the potting is delayed till the growth has started freely again. Most people will probably have done potting or chrysanthemum-cuttings for this season; but I shall strike the tops of certain varieties to get dwarf plants for rooms, &c. Cuttings for this purpose may be taken end of July or even later. The cuttings soon strike if kept close and shaded; I generally place a frame under a north wall to receive late cuttings. Planted Melons for late summer crop. Cucumbers are abundant now. I am giving my plants more room than I used to do, and, although a little sacrifice has to be made at the beginning, it will more than make up later. A cucumber bush has roots and fibre will be an immense number of fruits in a season if the roots are well supported. Cucumbers do not require much soil to start in, but frequent top-dressings must be given during growth and abundance of water. In very hot weather my Cucumbers are watered with the hose every morning. When Cucumbers are infested with red-spider it may safely be concluded they have not had water enough. I do not believe in coating the leaves of Cucumbers in the whole of the year, as is often practised; but when the plants are growing in beds a few of the bottom leaves may be shortened back with advantage to let in the light to colour the fruit, and where this does gradually there is no check, and as soon as the light lets in new growth starts away from the bottom of the plants, and, if one or two shoots are encouraged, there will be a second crop of fruit coming on before the plants have ceased bearing at the top. Tomatoes, I find, in such weather must have plenty of nourishment or the fruits will be small. I always mulch with manure and water freely, giving occasional doses of artificial, and I find it pays. Sowed several rows of William I. Peas. It is too late to sow Marrow Peas now; but early varieties will do very well. Shall plant American Wonder on the early border in about ten days' time for the last crop, and Marrow Peas planted in May will generally produce a second crop if all the pods are picked off. I find Walker's Perpetual come in useful for picking out. The Lettuce beds have all been mulched with old Mushroom-beds, and watered up; this keeps the soil cool and moist, and affords nourishment at the same time. All Lettuces are the better for trying up, except the small, quick-bearing Cabbage varieties, of which Tom Thumb may be taken as the type. Sowed a bed of Rampion; it comes in useful for salads. It has small round white tops like a Turnip Radish, and is cool and crisp. Globe Artichokes are being freely watered from the liquid-manure tank. House-leaves, diluted if strong, comes in useful now for many strong-rooting

subjects. Autumn-sown Autumn Giant Cauliflowers put out early in April are beginning to turn in now, and will be very useful if the weather continues dry, as on our hot soils Early London Cauliflowers open and are not good. Spinach substitutes, the best of which is the New Zealand Spinach, are grown instead of the true Spinach, which so soon bolts in hot weather. Sowed Vetch's Red Globe Turnips for autumn and early winter use. The drills were soaked with liquid-manure just previous to sowing; this brings up the plants quickly, and hastens the growth afterwards, and rushes them away from the fly. Finished putting in Pink-cuttings. Shall begin layering Carnations next week, as I like to get all such work done early. Watered Hollyhocks, Fuchsias, and Dahlias freely with liquid-manure. All these things have been mulched with manure, and so one watering a week, except in the very hottest weather, will suffice. Staked up herbaceous plants wherever necessary.

ROSES.

"BOULE DE NEIGE."

The year 1867 was a notable one for light Roses. The arrival at that date of such celebrities as La France and Baroness Roths-

child, not to mention Elie Morel, still often a very useful pale Rose, seems to have been overshadowed by the distribution the previous season of Mile. Thérèse Levet, Monsieur Noman, and Princess Mary of Cambridge; but it was in 1867 that Rose amateurs were excited by the announcement of a pure white Hybrid Perpetual, and there were then sent to this country three white Roses which are still unsurpassed in their respective lines. Of this trio by far the most important was one sent out by the great raiser (who has given the world more first-rate Roses than anyone else), Lacharme, under the name of Boule de Neige (of which an engraving is here given), a Rose whose whiteness has never been excelled, and not even equaled among large-flowered Hybrid Perpetuals until the arrival of the progeny of Baroness Goldchild—Mabel Morrison in 1878, and White Baroness and Merveille de de Lyon in 1882.

Rose "Boule de Neige."

Brier stock or on its own roots. In the latter state, however, it is not always easy to obtain, as cuttings of this Rose do not strike at all readily. Coquette des Alpes, Coquette des Blanches, and Perle des Blanches were also sent out by Lacharme, and Perfection des Blanches by Schwartz, and all four are White Roses with rather small flowers, but a similar inflorescence to that of Boule de Neige, but with a more decidedly climbing habit of growth in the case of the second and third, which make useful pillar Roses, as do two more recent seedlings from Schwartz, namely, Mme. Alfred Carrière and Faony de Forest, the latter an erect growing, rather rosy-white, the former an immensely vigorous climber, producing an abundance of most charming white flowers, tinted with pale yellow at the base. Mme. Louis Henry (Vve. Ducher, 1876) and Caroline Schmidt (Schmidt, 1882) complete the list of Hybrid Noisettes that are

worth growing; and for a small collection anyone wanting the best three would do well to select Coquette des Blanches and Mme. Alfred Carrière in addition to Boule de Neige. G.

4005.—**White Bankeian Rose.**—You must have patience with this Rose. It will flower all right when it has exhausted some of its vigour. The White Bankeian Rose always grows stronger than the yellow one, and requires more space. You have been well advised not to prune it. Do not cut away any of the growth all the time there is any uncovered wall space. When the allotted space is well covered, and no part of the wall visible, you may get a pair of shears and cut away all the growth that projects from the wall. This may be done as soon as the flowers fade; but after that you must only remove any long vigorous shoots until the same time next year. You are probably aware that it is the small spray growth that produces the flowers, and that these are mostly produced at first on the shoots farthest away from the centre of the plant.—J. C. C.

3998.—**Marechal Niel Rose.**—It is rather late in the season now to adopt the cutting-down plan with your Rose. It should have been cut back at least a month ago. On the whole perhaps you had better let your plant go unpruned this year, and train out any young shoots it may make. Next season as soon as the flowers are over you may cut it down, for even the old wood will send out young shoots, only it will take them a little longer to do so.—J. C. C.

— If all of the blooms are off of the plant, and it seems shooting out from near the base, I would remove the bulk of the upper growth that has flowered. If you can grow strong shoots this summer they will flower much better next spring than they did this, because you should be able to get longer shoots and they will be established. Two or three rods to a plant is sufficient, if kept clean and growing healthily.—P. U.

4008.—**Gloire de Dijon Rose.**—You are treating this plant very well indeed. As it is so healthy and clean, I would continue on the same lines. Unless growing very thickly, I would not thin out any of the wood, as it will produce such a quantity of blooms next spring. Yes, I would repot the Marechal Niel and keep it in the house, and under the same treatment as the Gloire de Dijon, cutting it back somewhat, so as to induce healthy and strong growth. The repotting of the other Roses must depend upon the state they are in, and as you are doing the others so well, I think you are quite capable of deciding for yourself.—P. U.

— I do not think the Gloire de Dijon Rose worthy of so much space under glass. There are so many much better ones. If you think differently you can, of course, let the present growth remain, only it must not be crowded. The shoots should be from 9 inches to 1 foot apart. The Marechal Niel should be shifted at once in a pot 14 inches or 16 inches in diameter; but do not prune it now the summer is so far advanced. You have done quite right in setting the other pot-Roses outdoors. If they want more root-room I should give it them at once.—J. C. C.

3985.—**Budding Roses.**—It is a little too early for this operation, as a general rule, although where stocks and buds are forward enough it may be done from June until the end of August. July is perhaps the best month, and if you can choose two or three dull days for the work so much the better. You should choose buds that are about three parts ripened, what is wanted being growth sufficiently matured to have the root or seat of the bud well down when the wood is removed, and yet having enough sap to allow of the bark being lifted easily. Cut out the bud in a scooping manner, inserting the knife about an inch above, and bringing it out again an inch below the bud. If you have chosen wood in the proper stage of growth the small portion remaining on the seat of the bud will be easily removed. Now comes the opportunity to see if the bud is really in the right stage or not, and unless the root be down low enough to rest upon the wood of the stock when inserted it is well to try another, unless the variety be very choice, and you do not mind the stock must be

prepared before cutting the bud, and the quicker and cleaner the whole operation can be managed the better are your chances of success. Whether the stock be a dwarf or a standard Brier you should insert the bud in the same way, and get it as near the base of the shoot as possible. Make a cut lengthwise of the stock—say, about 2½ inches—a short cross-cut may be made at the upper end of this to facilitate the easier lifting of the bark. Do not make your cuts any deeper than just necessary to cut through the young bark. Lift it with a piece of bone or hard wood, and slip the prepared bud under without disturbing the glutinous sap more than possible. Now tie in firmly, and in from three to four weeks you should be able to see if your work was successful or not. If not, try again, even up to the middle of September.—P. U.

The most important matter in budding Roses is to select the right time when the stocks and the buds are in the right condition. Unless the stocks can be heavily watered, budding cannot be successfully done till rain comes, as unless the bark works freely it is useless attempting to bud anything. When the Thorns will rub off easily the bark will generally work freely, and this is perhaps the best guide, though a man accustomed to budding can tell by the feel of the wood if there is a chance of the buds taking. Any way, it will be as well not to be in a hurry with the budding this season. We shall doubtless get rain enough to accelerate the flow of sap by-and-by, and during a showery time the buds take so much better. The operation of budding is simple enough. Two cuts are made just through the bark, one straight along the upper side of the branch 1½ inches long, and the other transversely at the upper end of the long cut. Lift up the bark with the flat end of the handle of the budding-knife, insert the shield of the bud, and thrust it home. The buds should be placed as close to the main stem of the stock as possible in the case of standard Briers, and as low down as possible in the case of dwarfs. In dry weather a little of the earth may be scraped away from the dwarf Briers, and the buds inserted in the moist bark so uncovered. The buds must be taken from healthy wood of moderate growth, just getting a little firm, but still quite elastic, the buds being plump, but not started. Buds which remain dormant through the winter always make good plants, and to keep the buds dormant the stocks should not be headed back till winter, and only partially then, the final heading back being done in March, just as the sap is moving. In cutting out the bud do not have the shields very large. Three quarters of an inch will be large enough, and of this two-thirds should be below the bud. Remove the wood from the bud carefully. Sometimes the centre or heart of the bud comes away with it, and then the bud will be useless. Tie in firmly with soft raffia, or cotton will do, the ties to be loosened as soon as the buds have taken, usually in about a month after budding. If left in much longer they will rot the bark. In dry weather it will be beneficial to mulch and water the stocks and sprinkle the buds.—E. H.

Seven Sister or "Cluster Rose."—This beautiful Rose has been exceptionally fine of late, and although termed a common one it is really one of the most useful of all. For covering high walls, climbing over old tree-stumps, or making any unsightly objects look beautiful it is a gem, for its strong habit of growth enables it to live where more tender sorts fail. I have it now covering a high wall, and basketfuls of bloom can be cut without being missed, yet it keeps pushing up rampant shoots from the base quite 10 feet high already. I retain these, and lay them in at full length, and after the blooming season is over I cut away a good deal of the old exhausted wood, and the blooms are remarkably fine and plentiful from the strong shoots. I find it a very good plan indeed to apply a mulching of half-decayed manure over the soil (early in the season) and almost all other Roses; especially in a dry season is this invaluable.—J. G. H.

HOUSE & WINDOW GARDENING.

CLIMBERS ON HOUSES.

CHARMING effects may easily be produced on a house wall by a judicious use of climbing plants, Honeyuckles, Roses, Wistaria, &c. But in suitable localities nothing can exceed the beauty of the Magnolia (Exmouth variety), as shown in the annexed illustration.

3992.—India-rubber plant.—Heat is usually supposed to be necessary to strike cut-

"Magnolia" on a house wall.

tings of this plant, but I have seen it done without, and you could not have a better time to try than the present. Take the cuttings off with a "heel," let them lie on a dry shelf for a few hours so that the cuts may heal, and then insert them singly in small (2½-inch or 3-inch) pots, filled with a mixture of equal parts of fine loam, sifted Cocoa-nut-fibre, and sand. Plunge the pots in ashes or Cocoa-nut-fibre in a box deep enough to allow of a sheet of glass being laid over, and keep them close, moist, and shaded until rooted.—B. C. R.

The young shoots need not necessarily be taken off—at least, not yet. It is quite possible that the upper shoots will take the lead, and the lower ones will not make much growth, but I should wait and see. When from 4 inches to 6 inches long the young shoots may be taken off, and planted in small pots, filled with sandy soil. If kept close and shaded they will root in the greenhouse during summer, though a little bottom-heat will help them. Still, if covered with a cloche or handlight they will root during the warm season.—E. H.

You may certainly strike this from cuttings, but they require heat, and a little bottom heat promotes quick rooting. Put them in a little propagating frame if you have such a contrivance, usually possessed by amateurs? Do not bruise the bases, and perhaps you have not kept the parent plant properly attended to. Here are a few wrinkles for the proper management of the Ficus. Keep the leaves always carefully sponged with tepid water to remove dust and other accumulations. During the summer season small plants are hewed about, and these are struck for eyes in the continent, and when received here by English nurserymen grown in high heat to get them ready for sale. Therefore, always when purchasing keep the plants in the warmer rooms, and not exposed to cold currents of air. When the cuttings are rooted, pot them on, and use for soil a mixture composed of sandy loam, two parts, added to one part of peat, with sufficient sharp silver sand to make the whole not too heavy. Pot firmly.—C. T.

3994.—Treatment of Indian Azaleas.—These are not amongst the easiest of plants to cultivate in a room, and special care is necessary

to make them flower. Indian Azaleas are, however, nearly hardy, and probably the warmth of the room (and the consequent dryness of the surrounding atmosphere), is partly to blame for the want of blossom. Thrip is almost certain to appear where Azaleas are kept in a dry, warm place, and this will prevent them from blooming. The signs of this insect pest are easily detected in tiny black and white spots on the back of the leaves, and these very soon spread until the leaf becomes a pale, dull colour, and eventually drops off. To eradicate thrip a bath of soft-soap and Tobacco-water should be made, into which the plants can be dipped every day for a week; afterwards syringing them with pure water. Two ounces of soft-soap and one of "shag" Tobacco, hoiled together until the liquid is a dark brown, can have enough cold water added to it to make four gallons in all, and be placed in a large earthenware pan or basin. If the plants are too large to be satisfactorily dipped they must be syringed from beneath, laying them on their sides to do this effectually. Small plants can be sponged leaf by leaf, but this is a tedious process in the case of Azaleas. To prevent thrip from attacking the plants again they must be allowed to stand out-of-doors in summer, in a situation shaded from the hot sun, and syringed daily, so as to throw plenty of water on the surrounding etonee (or thick bed of ashes), which will supply the damp night atmosphere they need. Plenty of water must also be given daily; neglect, in this particular, is fatal to any prospect of flowers, and Azaleas, being grown in peat, should have a full inch of room at the top of the pot for a plentiful supply, which must permeate the whole ball of roots. The special difficulty, however, comes in when it becomes necessary to take the plants indoors in September, unless there should be any small structure in which they can be placed for the winter. Damp air must be had for them, and the best arrangement that can be made is to place them in the window of a bath-room, from which frost is just excluded, and turn on the hot-water for a few minutes, morning and night, to moisten the air. Failing this, a large tray or zinc arrangement, or even a flat bath, can be covered with a layer of Cocoa-nut-fibre or Moss, and the plants placed on this, keeping the whole damp with a roset watering-pot in a room without a fire. During very severe weather the Azaleas should be lifted back from the window end covered with newspapers at night. They will stand a few degrees of frost under these circumstances, and be none the worse for it. Without the damp warmth of a conservatory the plants will flower late, but still they should do well, bringing their blossoms in April or May. As each blossom fades it should be removed at once (for seed-bearing exhausts the plants), and the plants should be kept rather close (i.e., without so much air as usual) and warm, with the air well-moistened, until July, when they are best out-of-doors until the autumn.—I. L. R.

3989.—Mackaya bella.—This is a South African plant, and grows very freely under greenhouse treatment; but it cannot be prevailed upon to produce its flowers in proportion to its growth. What it does require is to be encouraged to grow freely in a light position during the summer, so that the young wood is well ripened, for it is from the points of these well-ripened shoots that the flowers are produced. It may be propagated from cuttings struck in a close frame or handglass during the summer, so that nice, compact plants may be obtained by the end of the season. The resting period is from November until March, and during that time the plants do not need any water. When growth begins repot the plants in a mixture of sandy loam, decayed manure, and a little leaf-mould. They may require repotting a second time and growing on well, as advised above, until the end of the season. These must again pass through a season of rest, which is the period they require for flowering in the ensuing summer. They should be started in a temperature of 55 degs. to 60 degs.; but when the flowers are produced they will remain longer in good condition in a warm greenhouse. The plant is nicely figured in the *Botanical Magazine*, tab. 5797, from a plant that flowered in the Palm-house at Kew in May, 1860.—J. D. E.

OUTDOOR PLANTS.

THE ROUND-HEADED "HIMALAYAN PRIMROSE" (PRIMULA CAPITATA).

In reply to "J. H. Streatham," and others, this plant has a tuft of sharply-toothed, medium-sized pale-green leaves, and produces in autumn dense heads of flowers of the deepest Tyrian purple, enveloped in a white mealy powder, which shows off the blossoms to great advantage. It is very variable as to depth of colour, some forms of it being much superior to others. It is not a very vigorous grower, and, though quite hardy, it cannot be termed a good perennial in our climate, as it is apt to go off after it has flowered well; therefore, it is advisable to raise annually plenty of young plants from the seeds, which the plant produces freely in most seasons. These, if sown in pans of light soil in a frame or cool greenhouse, produce plants that will flower the second year with very little trouble. It thrives best in an open position in the garden, with a north aspect, in good loamy soil, which should be well watered in dry weather. The annexed illustration gives a capital idea of the Primrose in question when in flower, and it is best planted in colonies, or groups. R.

HERBACEOUS PÆONIES.

Or hardy flowers in the open ground in the summer-time, there are none so beautiful as herbaceous Pæonies. Among the flowers will be found every conceivable shade of crimson, purple, lake, cerise, carmine, together with the equally beautiful and more delicate shades of rose, pink, blush, flesh, and satin-rose. And then there are those with sulphur tints as well as those of pure and spotless whiteness. Fine massive white varieties exist too, as in the case of *festiva maxima*, having some of the inner petals occasionally margined and sometimes flaked with carmine. This is so good and distinct that no collection is complete without it, and one that everyone who sees it requires; consequently, though among the older kinds, it is still among those higher priced. Independently of the distinctive shades of colour above named, many varieties combine two or more shades. Another very pleasing feature to be found in many kinds is their fragrance, in no case overpowering, thus adding an additional charm to a group of plants which in their day are without an equal in the hardy flower garden. But with all their beauty, it can hardly be said that Pæonies have had either the popularity or the general cultivation to which, I feel sure, they are justly entitled, for it is rarely one meets with a good collection in private gardens. This may to some extent be accounted for, owing to the length of time the plants take to grow into size after planting. This varies from three to five years, according to the size of the plants themselves. This fact, again, may in not a few instances prevent their being planted in the open beds in the first instance, which is by far the best place for them; and consequently they are for the time being grown in the reserve ground till sufficiently large to occupy permanent beds. This, however, is a mistake and involves replanting them, which means the loss of one year more. Frequently I have seen them in shrubberies with scores of thin flowerless growths in them, causing annual disappointment to their owners. The worst place for Pæonies is the shrubbery, particularly where the plantation does not receive due care and is backed by trees of larger size. Pæonies, to do them justice, delight in, indeed must have, the richest of soils, and in all cases where possible be supplied with abundant moisture in summer. Avoid moving them when once well planted, for they will go on year after year rooting deeper and deeper and increasing the number of their rich and beautiful flowers annually. Let them in all cases occupy their permanent quarters where first planted, and if this should happen to be in a conspicuous spot on the lawn, there are plenty of things to carpet the ground and flower freely enough till the Pæonies are deemed sufficiently large in themselves. Tufted Pæonies are excellent for this purpose, and while delighting in the good soil at disposal, seem thankful for the partial shade from the Pæonies. And are benefited by the moisture applied to these plants. And if the eye tires of Pæonies, these may give place to Tuberoses, Begonias, Mignone-

tte, Ageratum, Heliotropes, or such things as are not deep rooted and are easily planted and removed. Those who require distinct kinds would do well to select them now they are in flower. E.

3987.—Soil for Petunias.—These are very easily grown, and are not very particular as to the soil need for them, but when they are grown in flower-pots it is well to do the best that can be done for them. They form roots so freely, and grow at such a rapid rate that the soil soon becomes exhausted, and the plants require feeding with manure-water to prevent the leaves from becoming yellow at the base of the growths. Use good yellow loam three parts, one part decayed manure, and one part leaf-mould, with a little crushed bone manure and coarse sand added to it. They require plenty of pot-room and a free supply of water when the pots are well filled with roots.—J. D. E.

— A compost of three parts fibry loam, one part horse-manure, fermented sufficiently to throw off the rank steam, half a part of peat, and sufficient sharp silver-sand to keep the whole porous, will grow Petunias well, providing, of course, other details, such as watering regularly and providing the plants with a cool position in a pit, shaded from the bright midday sun which influences paleness in the colour of the leaves. The young shoots should be regularly stepped when 4 inches long to induce others to grow, if large specimens are required, until six weeks before the time when they are expected to be in flower. Daily syringings will keep the foliage clean and healthy; this is best done in the evening after a hot day.—S. P.

— Pot them in old rotten turf and leaf-mould, two-thirds of the former to one-third of the latter. Very old manure would do in the place of leaf-mould. A little sharp sand should be added to keep the soil open and sweet.—E. H.

— A free, sandy loam suits these plants best, and a compost consisting of three parts of this material to one of leaf-mould suits them admirably. The double varieties may have a very little well-decayed manure also.—B. O. R.

— A compost consisting of loam, leaf-mould, and a fair sprinkling of sharp silver sand will suffice. Give the pots drainage, and not moderately firm. The plants will succeed well in a greenhouse. They may also be used as bedders for the open, and should be put out now. A bed of Petunias in fairly light soil is very charming, but the flowers should not be too tall; it is a mistake.—C. T.

A good White Pink.—An excellent variety is Mrs. Lakin. The flowers are very pure, large, not too full, and therefore do not

time to put in pipings, and then work for cuttings, and they strike easily, as recently pointed out.—C. T.

3991.—Creepers for walls.—If evergreen creepers are required for both the sites named nothing is better than Irish Ivy or the Ragneriana variety for the north-east aspect. *Euonymus japonica* and *E. j. aurea* will generally withstand the winter in such a site, and so will *Pyraeanthus crataegus*. For a south-west aspect *Ceanothus divaricatus*, *Escallonia macrantha*, and *Garrya elliptica* may be planted with safety. In the case of deciduous subjects there is a wider choice, as any of the following will succeed; *Clematis Jackmani*, or *C. montana*, *Aristolochia Sipho*, *Lonicera brachyepeda*, the common White Jessamine, *Gloire de Dijon* and *Aimée Vibert* *Roses*, *Kerria japonica*, and *Chimonanthus fragrans*.—S. P.

— Plant in the north-east aspect a selection of Ivies. There are beautiful things among Ivies to be had cheap now, or *Ampelopsis Veitchi* will soon cover the wall, and be beautiful in summer and autumn. If flowers are wanted plant Honeysuckles. *Jasminum nudiflorum*, *Fire Thorn* (*Pyraeanthus*), *Cotoneaster Simonsi*, and *C. microphylla* will cover the wall neatly, and be bright with berries in winter. On the south-west wall plant *Roses*, *Jasmines*, and *Clematises*. The *Wistaria sinensis* also will do well.—E. H.

— There are many creepers you might plant against your wall. In the south-west aspect such *Roses* as *Gloire de Dijon* and *Cheahunt Hybrid* would succeed, any good strong-growing climbers, and you may choose also any of the following: *Veitch's Virginian Creeper*, which is most suitable for a very high wall or the side of a house. It is quick in growth and clings closely. Then you might choose a good green-leaved Ivy, such as *Emerald Green* or *Gem*, or a variegated variety, *Lee's Silver*, but there are many other nicer things that may be chosen. Very beautiful is the old *Double Kerria* against a wall, smothering it with dense yellow flowers in spring, and it is not much sufficient use of in gardens. *Clematises* of many kinds can be chosen, such as *Jackmani*, its deep purple flowers very rich against Ivy leaves; *C. montana*, or the various handsome varieties that may be obtained, some with semi-double, others with single, flowers, the colours delicate and pleasing. *Jasminum nudiflorum* is beautiful in winter and

Round-headed "Himalayan Primrose" (*Primula capitata*).

split so much as many other kinds, and also sweetly scented. There are many White Pinks in gardens, and a beautiful edging is formed by the common variety, but the flowers of Mrs. Lakin are finer, the growth is strong, and a healthy clump will produce much bloom. In the month of June every garden should be gay with good clumps of the White Pink, and if variety is required from the ordinary kind, select Mrs. Lakin, and Her Majesty, or Mrs. Simons, which is a good kind for making a mass white, like little snowdrifts. Now is the

early spring; so also is the fragrant *Chimonanthus fragrans*, which blooms in the depth of winter, and has curious yellowish flowers of spicy, aromatic scent. Then you can select some of the Honeysuckles, Passion-flowers, for a warm corner. *Pyraeanthus*, which is a very handsome plant for a wall; it produces a profusion of white flowers at this season, and in winter its berries are orange-scarlet, and make a grand show of colour. A good specimen of it, with its abundant foliage and fiery coloured berries, is a fine winter picture. *Pyrus japonica*, the

Wistarias, and a few Vitis may be included. The Hop-leaved Vine is ornamental in character. There are plenty of good plants for walls without making a mere repetition of one's neighbours' things. It is a relief to see a wall covered with something besides the Common Virginian Creeper. Half the failures with climbers result from insufficient preparation of the soil. The roots are not properly laid out, and if bad, the soil should be made acceptable to the plants by preparing it properly. If you have a moist, shady corner, it would be better to put there the Ivies, which always, both variegated and green-leaved kinds, attain greater luxuriance of growth under these conditions. As regards plants for boxes, you may use such things as Pelargonium Mme. Creouse, to trail over sides, or other varieties; Toberone Begonias, Fuchsias, Canary Creeper, and other familiar things. In GARDENING, June 10th, page 209, "I. L. R." gives some valuable hints for window-boxes. You would do well to read them.—C. T.

ORCHIDS.

CATLEYA VELUTINA.

I AM asked by "Joseph Bidwil" what sort of a species this is, and if it worth his getting, as he sees that a firm at Bradford are offering it, but he has never heard of it before. The Cattleya in question was first sown in your city some thirteen years ago in the collection of Mr. Broome, who then resided at Didsbury. I may at once say that it is a very beautiful plant and very distinct, and if you are a grower of Cattleyas it is a kind which you ought by all means to add to your collection. This plant, many, on its first becoming known, wished to assert its hybrid origin, claiming as its parents *C. guttata* and *O. bicolor*, but although it somewhat resembles the last-named Orchid in its habit of growth, I, myself, can see no other resemblance, and the Sower appears to be too much developed in all its parts to be an offspring of either. Since its first introduction, the plant, however, has been met with on several occasions in great numbers, which leads me to think either that there are a good many more new Cattleyas in Brazil than we have ever dreamed of; or, if they are hybrid kinds, we shall yet have to find their parents. Now, this plant, although it varies considerably from bad to good varieties, has not much variation in its colour. As a usual thing, it may be said to have slender stem-like bulb, varying from a foot to 18 inches in height, and bearing upon the top a pair of ample leathery leaves, from between which the scape appears, bearing two Sowers, and I cannot call to mind ever having seen more horns upon a single scape, so that it is as well to have a plant with more than one leading growth. These Sowers are nearly 4 inches across, and very sweet scented, resembling the fragrance of Violets. Sepals and petals about the same size, of a rich tawny-orange ground colour, thickly spotted with maroon-purple. The three-lobed lip has the side lobes curved upwards, partially enclosing the column, creamy-white, streaked at their base with rosy-purple; middle lobe large, covered with a short velvety down, white, strongly veined with radiating veins of purple. It has a stain or blotch of orange at the base, and round the apical margin is a stain of soft yellow. These flowers last a long time in perfection, and perfume the house in which they stand beautifully. I have been describing a good variety, be it understood, but I have seen a great many Sowers which would not come up to it. Nevertheless, they only differ in their brilliancy of colour. It blooms in the autumn months, at which time Sowers used to be scarce, but we now have a goodly number all the year round. Now, to grow this plant well requires considerable care, but yet only such care as should be given to all Orchids; but some of my readers imagine when I say a plant is very easily grown that no care is requisite at all, and they treat their plants with a great deal of carelessness. Upon this subject I have had two letters recently, and my friends may take this for an answer. This Cattleya I have before said makes a very slender stem-like growth, and, therefore, it requires extra care in its management. It must be well drained and firmly potted, using good peat fibre and chopped Sphagnum Moss, and the rhizome should always stand upon the surface of the soil. The plant

does not require quite as much water to the roots during the growing season as do many of the same genus, and neither can it withstand so much drying, so, therefore, in the winter extra care is necessary to keep the plant nicely moist in order to prevent its thin bulbs from shrivelling. It likes when growing to stand at the warm end of the stove or Cattleya-house, and to have a good moist atmosphere maintained in the house, which should also be well and properly ventilated. The plant should be well exposed to the sun and light, shading only when the sun shines very hotly, and then one must remember that their plants are under glass, and if the leaves are to be preserved in a sound and healthy condition a slight shade is necessary. The plants during the winter must be kept sufficiently cool to prevent them starting into growth at that season. MATT. BRAMBLE.

CATLEYA EL Dorado AND ITS VARIETIES.

I AM asked by "O. Hughes" to say something about Cattleya Wallisi, so as to enable him to grow it and to Sower it? and as this is a pure white form of *C. Eldorado*, more correctly named *virginialis*, I have thought it best to make a general chapter of this gorgeous form of the *C. labiata*, which moreover is as distinct as it is beautiful and unlike most of the other forms of that species which grow naturally in comparatively cool regions and a tolerable equable atmosphere, whilst *Eldorado* is found in the hot district of the Rio Negro somewhere near about the place of its junction with the River Amazon, and this region we are told by Wallace is very hot and at some time in the year very dry, so that to grow this Cattleya well it must be given a lot of heat, and I have succeeded with this plant and its varieties in the best manner when I have grown it in the East Indian-house, maintaining for it a good moist atmosphere. It is now about twenty seven years ago since the typical plant was introduced through M. Linden, of Brussels, and a year or two afterwards the plant was brought to me; since then, however, I have upon several occasions received plants from its native home, and it is a plant which has always done well with me. Upon one occasion I had a very good consignment of the whitovariety called *virginialis* sent home. These plants arrived home in the month of December, and by the time we get them trimmed, washed, and potted, and placed in position, with East Indian temperature, the days began to lengthen and the sun to get more power, and so the plants grew and went straight on until the month of September, when many of them Sowered. I have also had the fine variety called *splendens* sent me some direct, and all have done well under the treatment recommended above. They were potted at first in pots, having only their drainage material in, and as the plants began to root the soil was put in, and so the plants were built into the soil, which they soon occupied, and many roots peeped out, and in these pots they remained for three or four years, simply picking the surface over, and renewing it every spring before the plants began to grow afresh. The soil should be good peat fibre, from which all the fine soil has been beaten, mixed with chopped Sphagnum Moss. This Moss, with the Cattleya soil, I have been called over the coals about by many Orchid-growers, but I have always maintained it was right in recommending it, and I have always said the rotting of the roots came about by overwatering the plants, and I have proved this, for in the case of Cattleyas grown in two collections half a mile apart, the water supply coming from the same source, I find the man who has his plants potted in all peat has nearly all his roots rotted quite away and the plants look miserable, whilst the other collection is potted as I recommend, with about a fourth of the whole chopped Sphagnum Moss. These, with careful watering are rooting and doing well; so I see that there can do with Sphagnum Moss to these Cattleyas as well as I can, and so I shall continue to recommend its use. I know nothing of the *Polypodium* fibre, which I have seen used by Belgian growers, but in England it does not find much favour, and, indeed, I cannot see anything which I can say in its favour. The best varieties of *C. Eldorado* are *splendens*, which is a magnificent form of the typical plant, which it is similar in growth. The flowers measure between 5 inches and 6 inches across,

the sepals and petals being of a full clear rose. The large lip is beautifully toothed round the edge; the throat is rich orange, and surrounding this is a broad belt of white, leaving a broad marginal border of rich violet-purple. About three Sowers are the most I have seen it bear upon the spike. The variety *virginialis*, which the enquirer has by the name of *Wallisi*, is a beautiful pure-white flower, having a broad hint of orange in the throat, and the edge of the lip is prettily toothed, besides yielding a delightful perfume. The variety *crocata* is also another, but this gives me less pleasure than the two recommended above. The sepals and petals are white, suffused with light-rose or mauve, and the lip is deep-orange at the base. Nevertheless, all the above are worth growing, and their Sowers last a long time in perfection. It is well not to allow them to remain too long upon the plant; but they should be cut and inserted in the little tubes which I have so often spoken of, and placed in and about the house in order to produce a good effect. MATT. BRAMBLE.

4004.—Orchids in a greenhouse.—You do not say whether the Orchids are to be grown with other plants in the greenhouse, but I imagine it is so. In that case the choice is not very wide, although your winter temperature is suitable. In the summer I am afraid it is likely to be a little too high. I will, however, give you the names of a few sorts which I grew for four years with other plants with a fair amount of success. I must, however, first say that the results depend more on the attention given to minor details than on the temperature. To know when to give water and when to withhold it, and when to rest a plant, and for how long, are points in the management that require some amount of practice and observation to manage them properly. I have grown and flowered successfully every year *Odontoglossum grande* in a winter temperature of about 45 degs. to 50 degs., and after it had Sowered placing it in a warm vinery to make its growth, and always keeping the soil more or less moist. *Odontoglossum Rossi majus* does exceedingly well with other plants, and blooms regularly in the spring; and about a month later *O. Alexandrie* and *O. Pescatorei* will blossom if the treatment is right. *Onocidium oculatum* and *O. flexuosum* are easily managed Orchids that flower regularly every year. I started with half-a-dozen varieties of *Lycaste*, but only half of that number were satisfactory in such a low winter temperature. These were *Skinneri*, *Skinneri maculata*, and *aromatica*. I see by my notes, made in 1890, that I had the sweet-scented *Odontoglossum pulchellum* in Sower on May 15th that year. *Cypripedium insigne* anyone can grow who has a warm greenhouse in winter, and it will Sower regularly every autumn if it is kept in a fairly high temperature all the summer. My favourites of all Orchids suitable for an amateur to grow are the *Madevallas*, and the best of these is *Harryana*, the flowers of which are of violet- crimson colour, and they are freely produced, the plant being at its best about the middle of March. I found this and *M. ignea* very easy plants to grow if they did not get too much moisture in the air during the winter. *Coeloglossum cristata* is a very accommodating plant, and is well managed and Sowered every year in hundreds of gardens where no other Orchids are grown.—J. C. O.

—When the temperature is never under 45 degs., all the cool-house Orchids will do admirably, but the dry atmosphere which is almost necessary for Cape and New Holland plants, and the abundant ventilation does not suit the Orchids; they must have a moist atmosphere, and drying winds blowing through the house are fatal to the Orchids. I would try the *Odontoglossum*, such as *O. orlopum*, *O. Pescatorei*, *O. Cervantesi*, *O. serdatum*, *O. Edwardi*, *O. Rossi*, *O. luteo-purpureum*, *Epidendrum vitellinum majus*, *Maxillaria grandiflora*, *Lycaste Skinneri*, *Madevallas Harryana*, *M. Veitchianum*, and *M. Lindeni*; *Cypripedium insigne* in variety; *Bletia hyscolinthina*, and *Dendrobium Jamesianum*.—J. D. E.

Drawings for "Gardening"—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

TREES AND SHRUBS.

THE COMMON YEW AND ITS VARIETIES.

THE varieties of the common Yew (*Taxus baccata*, Lin.) are numerous, and half a dozen of them at least are popular favourites—namely, *T. b. adpressa*, which was erroneously considered a species; *T. b. hibernica*, which has a majestic columnar habit; *T. b. Dovastoni*, which has its branches staged in pendent whorls; *T. b. variegata aurea*, which has the leaves variegated with yellow; *T. b. v. argentea*, leaves variegated with white; and *T. b. fructu-luteo*, of which the fruit is yellow. The other forms, many of which are handsome or interesting, are more rarely met with in cultivation; still a pretty considerable number of them might be enumerated. Loudon described six.

M. Carrière reckons twenty-six, of which he gives descriptions and synonyms. The catalogue of *M. A. Lavallée* mentioned eighteen, and in some collections several varieties are to be found which are not included in any of the works cited. Now the question arises, Can a selection be made from amongst the numerous ornamental varieties of the old Yew of our mountains? Undoubtedly it can; all of them have not an equal claim to our favour. In addition to these which I have just mentioned as being most generally planted, and which deserve a place in every garden, the following varieties may be recommended with confidence: *T. b. erecta* (pyramidalis or stricta), which has an elegant, fastigiate, close-branched habit, slender, erect branches, and straight, slender, deep-green, and short-pointed leaves. *T. b. cheshnuntensis*, which originated at Cheshnut, has a close-branched habit, but the branches are not fastigiate.

The leaves are dark green on the upper surface, glaucous underneath, slightly curved and long-pointed. Over and above their more or less elegant habit, these Yews possess another source of ornament in their fruit. Everyone knows the pretty red berries which adorn these trees in autumn, and which continue to do so until the frosts come on. Some particular trees are sometimes profusely laden with them; others seldom or never bear any, which is chiefly the case with the cultivated varieties, and this is not surprising when one remembers that the tree is dioecious, besides the fact that certain forms which have been established by means of grafting or budding are only capable of being produced with male plants. I have observed in several parts of France that the Yews bear an unusually great abundance of fruit. In the nurseries of *M. Louis Leroy* at Angers, this

abundant fructification was observable even on the youngest plants, which were growing in beds, and most of these if they had been potted would have formed charming ornamental subjects for the drawing-room or the dinner-table. It occurred to me to gather a few branches and closely examine them. At first the forms and colours appeared identical, with the single exception of the pretty yellow-fruited variety; but I was soon struck with differences of characters which at first sight I had not noticed. These differences were not confined to the fleshy cup which forms the coloured and pulpy part of the fruit, but also extended in a remarkable manner to the nucule or seed itself. The fruit gathered from different plants exhibited fixed characters, and I thought it might be useful if I described them more minutely than anyone had

the greater part of the seed, which is ovoid in shape, brown or russet-coloured on two-thirds of the upper part, roddish on the lower part, blunt at the top, with slight ribs, and finely dotted on the surface.

T. b. VARIEGATA AUREA.—Habit and foliage similar to those of the type, sometimes more compact. Leaves more or less margined with yellow. Scales at the base of the cup imbricated, blunt, of a straw yellow colour, tinged with violet. Cup like that of the type. Nucule or seed oval roodish, slightly or not at all angular, pointed at the apex, and with a triangular or quadrangular scar or hilum. The silvery-variegated variety (*T. b. v. argentea*), which is very distinct, by its white markings, from the preceding variety, is easily mistaken for it in the autumn, when the silvery variegation takes on a yellowish tint.

OUR READERS' ILLUSTRATIONS: Old English Yew at Coniston. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. John Lowe, M.D.

T. b. FRUCTU-LUTEO (see Fig. 1, page 234).—Habit erect; branches more or less divaricated; leaves short, linear, short-pointed, deep-green on the upper surface, pale underneath, and slightly curved. Scales obtuse, lemon-yellow in colour, tinged with violet at the top. Cup oblong, of a fine golden-yellow colour, very much hollowed out in the interior, with an oval or slightly angular orifice and completely enveloping the seed, which is seated at the bottom of the cup. Seed oval, compressed, of an olive-green colour, and having a large oval hilum, the circumference of which is finely plaited; apex of the seed obscurely keeled, depressed, and with a blunt point. This variety is in some collections erroneously grown under the name of *T. cuspidata*, a Japanese variety which some authors consider a species.

T. b. DOVASTONI (see Fig. 2, p. 234).—Habit,

provisionally done. In order to show these fixed diversities plainly I had the accompanying illustrations drawn, and they will give a very clear idea of the differences of characters, especially as regards the nucules or seeds, which are represented as of double the natural size. These illustrations and descriptions may prove useful to anyone who undertakes a monograph of the genus, and also may assist growers in identifying forms which are difficult to distinguish from others. I intend to continue them next year in the case of any other varieties that I may find bearing fruit.

TAXUS BACCATA (type).—Easily distinguished by its spreading habit, horizontal branches, linear-obtuse leaves, which are more or less curved and terminate in a sharp or slightly blunted point. Fruit cherry-red, cup pitcher-shaped, with a rounded orifice end enveloping

pyramidal; branches sub-verticillate, spreading reflexed at the extremities. Leaves large, distichous-scattered, very much curved, cuspidate, dark-green on the upper surface, pale underneath. Scales obtuse, of a straw yellow colour, edged with violet. Cup oblong, rather short, of a lively cherry-red colour, and with a square orifice. Seed very deeply sunk in the cup, of an oval, compressed shape, and having an oval hilum with a pitted circumference; top of the seed bluntly square, scarcely pointed; surface of the seed rough.

T. b. ADPRESSA (see Fig. 3, p. 235).—Habit spreading, sub-horizontal; branches short. Leaves distichous, short, linear-obtuse, short-pointed, deep-green on the upper surface, pale underneath. Scales obtuse, of a straw yellow colour, tinged with violet at the top. Cup vermilion-red, very broadly angled, not covering the seed,

which is ovoid, depressed, terminating very abruptly in small points at the top, which is twice or thrice keeled, and has a depressed centre with a projecting point; hilum heart-shaped. This variety was considered a species by some authors, and had also been described as a *Cephalotaxus* (*C. tardiva*), but it has frequently been clearly proved that it is a sport from *T. baccata*. At the present time, in the park of Megandais (Mayenne), which belongs to Count G. de Cray, a Yew may be seen, several large branches of which exhibit the characteristic

Fig. 1.—The Yellow-fruited Yew (*Taxus baccata* fructu-luteo). (See page 233.)

both of the type and of *T. h. adpressa* very clearly together, and this is probably not the only existing case which might be instanced.

T. b. MUSENICA (see Fig. 4, page 235).—This is the pyramidal Irish Yew, which bears the same relation to the common Yew which the spiry Cypress of the South does to *Cupressus sempervirens*. Habit fastigiata; branches short, stout, close-growing, erect; leaves stout and long, linear, aciculate, more or less straight or curved, deep-green on both sides. Scales obtuse or slightly acute, of a straw-yellow colour tinged with violet. Cup of a lively cherry-red colour, slightly oblong in shape, with an angular orifice and half covering the seed. Seed oblong and ovoid; hilum sunken, triangular or quadrangular, margined with furrows and folds; apex of seed mucronate. The variegated form of the same variety (*T. b. h. variegata*) has the same habit, with loeवन more or less margined with yellow. A fine old Yew is illustrated on page 233.

Garden.

3995.—Flowering shrubs.—Evergreen shrubs growing the knight named are not so plentiful. *Ligustrum japonicum* (the Japanese Privet) is a showy subject when covered with its long spikes of Lilac-shaped white flowers and glossy green leaves. The Strawberry-tree (*Arbutus Unedo*) would probably answer the purpose, and grow that height in a short time. Rhododendrons or Kalmias would be really first-rate subjects for such a place, but if the natural soil is either composed of clay or has limestone or chalk in it these plants would not grow. It would be necessary to entirely remove the whole 2 feet deep, and replace it with peat. *Magnolia grandiflora* would most likely be suitable for such a site, and being evergreen would be of the right kind. A sandy loam is the soil which suits this subject the best. Amongst deciduous trees *Philadelphus grandiflorus*, *Spiraea crisifolia*, *Deutzia scabra*, *D. crenata* fl. pl., *Lonicera tatarica*, *Amelanchier Florida*, *Lilac* Charles X., *Magnolia speciosa*, and *Gulder Rose* (*Viburnum opulus*), are free-flowering subjects, and of quick growth also. The month of April in a good time to plant all evergreens, and October or November for deciduous trees. With the exception of the Rhododendrons any good garden soil will do the others named. A mulching of manure over the surface at planting time will not only preserve the roots from frost during the winter,

but will conserve the moisture in the summer if the weather be dry.—S. P.

— Yours is a none too easy question; but the following will prove suitable. You should have given the locality in which you reside, as that is very important. *C. biguonoides* is a good tree, the flowers not unlike those of a Horse-Chestnut, and appear in August. It likes a moist and rather sheltered position. The Strawberry-tree (*Arbutus Unedo*) is worth noting, the shrub being evergreen, and blooms freely. But it is not thoroughly hardy, and if your garden is not warm it is better not to risk it. *A. Androsace* is a common shrub, and hardy, evergreen, and handsome in aspect. Amongst the Magnolias you might try *M. glauca*, which grows from 12 feet to 15 feet in height; but here, again, it is not always satisfactory. The foliage is evergreen, and the white flowers are powerfully scented whilst they are produced in the month of July. If you care for Rhododendrons you might make a selection of this, some finely-flowered kind as *Blandyanum*, or you can choose the picturesque Medlar, a very beautiful tree to my mind when spreading out its characteristic growth on a lawn, whilst the Quince is also available. A good specimen of this tree is full of charm, the branches clothed with leaves, and a perfect picture. The Californian *Garrya elliptica*, an evergreen of handsome aspect, is useful, and its catkins are produced in winter, and are pretty when out for placing in a vase in the house. Varieties of the Syrian Mallow (*Hibiscus syriacus*) may be selected, and the shrub flowers in late summer; but the soil must be moist and fairly rich. It is called in some nurseries *Althea frutex*. The Fuchsias, such as *F. Riccartonii*, are very lovely, their slender shoots being perfectly covered with crimson flowers. Then you may have *Thorus*, such as Paul's Double Scarlet, *Laburnum*, or *Hydrangea paniculata grandiflora*, which produces immense heads of flowers. I should have thought, but, of course, I am not competent to really advise without seeing the place, that it would be better to form good hods of dwarfier shrubs, of which there is a host of beautiful kinds, on the turf. The *Hydrangea*, *Daphne Mezereum*, and many others are excellent thus arranged.—G. T.

3971.—Caterpillars in a shrubbery.—The plant in your shrubbery which is being destroyed by caterpillars is, I have no doubt, from your description, the Spindle-tree (*Euonymus europaeus*), and the caterpillars those of one of the small Ermine Moths (*Hypoconema Euonymellus*). They should be shaken or beaten out of the bushes and trampled on, or the bushes may be well syringed with 12 lb. of soft-soap and the extract from 5 lb. of Quassia-chips, added to 100 gallons of soft water; but the mixture must be applied with considerable force to break the webs.—G. S. S.

3996.—Planting Rhododendrons.—These shrubs do very well in good fibrous loam, but an admixture of peat will certainly benefit them. Plant in the autumn, and do not let them get dry at the roots, as few shrubs suffer more from drought than Rhododendrons.—A. G. BUTLER.

— These plants will not exist in lime-stone soil let alone chalk. It will be necessary to remove the whole of the natural soil 3 feet deep, and replace it with peat. If leaf-soil could be obtained it would economise the peat one part in three. The month of March or early in April is the best time to plant.—S. P.

— It will be a waste of time and money to plant Rhododendrons in a lime-stone soil; but if a bed is made of peat and leaf-mould they will do very well.—E. H.

— So far as the safety of the plants is concerned you may move them as early as the middle of September, but I do not advise such early planting, for the reason that the flower-buds are not then perfectly formed. The end of October is the best time, although they can be moved with safety from that time up to the end of March. Rhododendrons will not grow in some kinds of loam; whether it will in that to which you refer I cannot say. The loam that I have had to deal with in growing acres of these plants is of a soft, friable nature when dry, and made up of minute particles; but if it is moved about when it is wet it works into a sticky paste. If your loam is at all of a sandy character the probability is that they will do well in it. Two years' experience with, say, a dozen plants, would decide the question better than any suggestions that can be given you.—G. C.

— There are many questions asked from time to time about soil for Rhododendrons, but I do not think I can better that mentioned in Mr.

Anthony Waterer's advice on the matter. He is one of the greatest Rhododendron growers in the world. He says that all American plants like peat soil best, and, of course, one remembers the time when it was considered useless to grow the shrubs in any other kind of ground. Rhododendrons, the most important of them all, as well as other of the more vigorous habited plants, succeed in almost any soil that does not contain lime. In many sandy loams they grow with as much vigour and luxuriance as in peat—in fact, almost any soil from lime and chalk may be rendered suitable for them by a liberal admixture of leaf-mould or any fibrous material, such as the parings of pasture land. When the soil is poor, cow-dung in a thoroughly decayed state forms one of the best manures for these plants. Here then you have an answer to your question in respect to soil.—V. C.

— Some persons have an idea that peat-soil of some kind is absolutely necessary for Rhododendrons. This is an error; they will grow in loam, if it is mixed with sand and a good dressing of leaf-mould. In the case alluded to here they would probably not succeed for lime and chalk soils are both injurious, and it may be fatal to them. I should hesitate to plant them on the limestone. There is no doubt that good fibrous peat is the best soil for Rhododendrons, and it might be necessary to plant them in peat and leaf-mould in this case. They have such masses of fibrous roots that it is safe to plant them almost at any time. The best periods, if there is a choice, is autumn and spring.—J. D. E.

3993.—Tuberous Begonias.—It will be needless to put out the Begonia in beds if they have been hitherto grown in heat or in the shade without hardening them thoroughly in a cold frame or at the base of a south wall, so that the leaves may be made quite hard to endure the force of the sun during the hottest part of the day. It is by planting Begonias that are not properly prepared that so many persons fail in their culture as bedding-plants. When the leaves and stems are developed in either heat or shade they are rendered so soft and sappy that the least blast of sun upon them scalds the leaves and checks the growth. If no other convenience exists beyond a window for raising the plants, directly two or three leaves appear in April the plants should be stood full in the sun

Fig. 2.—Dovaston's Yew (*Taxus baccata Dovastoni*). (See page 233.)

and out-of-doors free from frost. Before planting, thoroughly dig over the ground, adding a small quantity of horse-manure if the soil is poor. Soak the soil in the pots well before planting, and cover the soil about the plants in the beds with some low-growing plant, such as *Sedum glaucum* or *S. Lydium*, *Herniaria glabra*, or *Veronica repens*. The advantage of this covering is manifold. The soil is hidden, a good contrast to the flowers above is provided, and the soil is kept moist about the roots of the Begonia, in addition to preventing the soil

being splashed on to the Begonis blooms by heavy rains. Abundance of water should be given to the plants during dry weather, as they are moisture-loving subjects.—S. P.

The Begonias will do very well planted out-of-doors in good soil. The best growers dig the ground deeply or trench it up to the depth of about 18 inches, and during the process they work in a liberal dressing of decayed manure. During the hot dry weather we are experiencing, it will be necessary to water the beds before planting, and to water them well

pot in any frost-proof place, such as a kitchen cupboard or cellar, placing some Cocoa-nut-fibre among them.—B. C. R.

Plant in beds any time now, and lift the tubers before frost injures them in autumn, and pack close together in boxes of sandy soil, and keep cool and dry during winter. Must not be exposed to frost, but in other respects will be kept quite cool.—E. H.

CHRYSANTEMUMS.

CHRYSANTEMUM OUTTINGS.

In the case of new or scarce varieties very often a great difficulty is experienced in obtaining a sufficient stock of outtings. Some are so shy of throwing up shoots during the dull days of winter that any means taken at any other time to facilitate the production of outtings is time well spent. Instead of throwings way side shoots that are removed constantly from the plant during the summer, or suckers from the base—many plants throw these up freely during June—insert them singly in small pots in sandy soil, place them in a cold frame, keep close and shaded till rooted, then give abundance of air to induce them to grow stocky. As soon as the pots are full of roots shift the plants into 4-inch or 5-inch pots, using moderately rich soil, pressing it down hard, and short, stocky growth, so desirable for producing good outtings, will be made. Stand the plants out-of-doors in an open position, allowing one stem only to extend. This will attain a height of from 1 foot to 4 feet, according to the variety, and will produce one bloom. Such plants are useful for decoration on the side stages of the conservatory or elsewhere. Cut them down rather early after blooming, and they will be certain to produce good suckers. I find that they always throw up more freely when grown in small pots in the manner described than when grown in the orthodox way, for affording exhibition blooms, as no doubt the constant removal of the suckers during the summer treatment weakens the plants for the after growth of outtings. This does not occur when grown as above indicated, as the primary object is not the production of large flowers, but sturdy shoots for propagation. This is a system I can highly recommend. E. M.

SEASONABLE CULTURAL NOTES.

PLANTS intended for the production of large blooms are now making rapid progress since forming the additional shoots consequent upon making their first break. Restrict the number of branches absolutely to three where the finest blooms are required, removing all side growths as fast as they form at the nodes, thus concentrating all the energy of the plant into the selected shoots. Many of the plants, especially those known as the Queen type, have shown a disposition to premature bud formation, which is difficult to account for, except, perhaps, the hot weather experienced for the last two months has hastened the plants unduly. The only remedy I know is to pinch out all buds as fast as they appear, inducing the plants to make fresh and clean growth. When once a fresh start is made, as it were, after a continuance of bloom-bud formation, seldom do the plants show a disposition to return to that state afterwards. No time should be lost now in placing the plants in their summer quarters, so as to give the newly-made growth the full benefit of light and air, so that they may mature their growth, as it progresses. So much depends upon the state of the shoots as regards their being ripe, or what is perhaps a better term to employ—maturation. All the difference possible exists between the blooms produced from plants that are of mature growth and those that are otherwise. It is not possible to obtain blooms, especially in the incurved section from plants that are of immature growth that contain all the essentials that go towards making a bloom perfect—viz, size, depth, solidity, and richness of colouring. Plants that are soft in the texture of their wood cannot give blooms remarkable for depth and solidity. They may be large in diameter, but they will be devoid of that deep and solid character which is pleasing to cultivators of the incurved section. As it is possible for all with the necessary conveniences to have blooms of the character indicated, I would impress upon beginners the absolute necessity of attending to the details as advised of affording the plants all

the available space to effect the object. I prefer to spread out the three shoots in such a manner that the leaves of one does not envelop those of its neighbour. By temporarily fastening two upright stakes to the cross rails or wires, which support the plants in their summer position, the shoots can be readily fastened to these stakes, and will then have all the light and air necessary. The third shoot is made fast to the one stake in the pot, the remaining two are looped to the centre stake in the autumn when the plants are removed to their flowering quarters. Plants upon wallaces making most satisfactory progress where they have been regularly supplied with moisture at the roots, and an occasional wetting of the foliage in the evening after a hot day. With the exception of a slight attack at the present time of black fly in the points of the shoots, the plants are quite free from insect pests. As the shoots multiply they must be attended to, over-crowding of them means a soft growth, and this results in small blooms, as well as rendering them more liable to injury from frost. Space ought to be allowed for the full development of each shoot, cutting away all surplus growth. E. M.

THE ORANGE AND CITRUS FAMILY.

THESE are not apparently nearly so much grown now as they used to be for large plant houses and conservatories. The time was when they were frequently to be met with in gardens both large and small. Palms of large growth and Tree Ferns also must be credited with elbowing these plants out of their accustomed places. These latter are of much nobler growth, it is true, as far as growth goes, but when the Oranges, Lemons, and others of the tribe are bearing good crops of their luscious-looking, deep-golden or pale-yellow fruits, they are worthy rivals to even these other princes of the vegetable kingdom. Oranges and other fruits of the same class have, I know, in some instances—in others in all probability—become unpopular through the plants for some reason or other failing to bear good crops of fruit. This may be caused through the plants having remained far too long without any attention being given them at the roots. They do not, it is true, require repotting or retubing so often as many plants do, but attention should be given every year to

Fig. 3.—The short-leaved Yew (*Taxus baccata adpressa*). (See page 233.)

after, besides mulching the surface of the ground under the plants with decayed manure to prevent evaporation. After they have bloomed and the stems are decayed, dig up the tubers, dry them a little and keep them in dry sand where frost cannot reach them in winter.—J. D. E.

You may put out the Begonias at once, and the quicker they are in position the better. This flower is getting more popular each year for bedding, and the reason is not far to seek. They require a rich, well-manured, but light soil, and in dry weather give copious waterings, as the Begonia likes moisture, whilst a top-dressing of Cocoa-nut-fibre refuse is also an advantage. They revel in moisture, but will succeed in the open, as shown by the splendid displays in gardens. But when under glass partial shade, or light screen from the sun is needful. Always, however, when in the open and the soil is dry, maintain the soil in moderately moist condition. The best plants can be lifted with good balls of soil before frosts have touched them, and potted. They will bloom under glass for some time. The winter treatment of the Begonia is, as soon as frost has set down the stems, to lift the tubers, and if named, take care to attach a label to each variety, and when thoroughly dry, store them away in shallow boxes, covering them with Cocoa-nut-fibre refuse. Place under a greenhouse stage, or in some dry corner away from drip from plants. Examine the tubers every now and then, and if going at all mouldy dust with sulphur. In spring, when growth is commencing, they may be repotted, shifted as required, and kept in a warm growing temperature. Before planting out harden off, and then a good display of flowers may be anticipated.—C. T.

Harden the plants off well, and plant them out as soon as possible in a bed of mellow soil, made rich by the addition of very old manure, leaf-mould, or spent Hops. They must be well watered until thoroughly established, and if the weather continues as at present it would be as well to shade them during the hottest part of the day—at least for a time. As soon as the first slight frost in autumn has just touched the top, lift the roots with some earth round each, lay them out in a dry shed or box for a fortnight or so, then carefully rub off all the soil, and store the tubers in a box or large

Fig. 4.—The Irish Yew (*Taxus baccata hibernica*). (See page 234.)

top-dressing the plants with good loam and some fine lime-rubble; whilst in the summer, if there is a crop of fruit which requires extra assistance, the plants may be mulched with cow-manure. When it is seen that a change of soil would be beneficial, it should be done thoroughly. This work, where necessary, might be done at once, for none of this family take much of a rest, particularly where the trees are bearing fruit in their various stages of development, some ripening, others just grown, and others quite small. The

greatest care should be taken at such times with the roots; they should be treated as carefully as those of orchard-house trees when these are reported, merely removing the soil around the sides by pricking it out, saving the roots as much as possible. The very best loam obtainable should be given them, adding thereto some fine lime-rubble and road-scrapings, if found necessary, so in the case of rather close loam.

FIRM ROTTING should be insisted upon. The common enemy of this class of plants is the scale, one kind of which seems almost peculiar to them. A thorough cleaning should be given the plants where the scale is present; if there are not many the advice holds good all the same as if the plants are badly infested. Labour spent in clearing off the few is a decided gain. Any ordinary, but well-proven, insecticide, will answer for this purpose, taking care not to injure the fruit where there are any. The dessert kinds are well worth growing for fruiting as small plants. In one place where I once served the Orange marmalade was made from home-grown produce, whilst the Lemons frequently came in very useful when foreign-grown ones were scarce or the stock ran out. These were very fine old plants growing in square wooden tubs and bearing heavy crops of fruit, although they were actually stood out-of-doors in the summer, and wintered in a greenhouse heated by the old-fashioned flues. I have noted that the florists cannot always find a supply of Orange blossom so easily as they need to do. I have been asked several times where it could be obtained, old sources having run out. There may be in time a return to older tastes again, Oranges, &c., coming once more to the fore and finding favour. I hope this may be so, for finely-grown plants of these are splendid objects for terraces, infinitely better than many of the more weedy plants so frequently used. It takes many years, I know, to work up a good stock of large plants, but methinks it would pay to do so as a change to the present order of things. What is wanted in the case of these fruits is more careful attention. H.

THE KITCHEN GARDEN.

SUMMER VEGETABLES.

FRESH vegetables that we rightly set so much store by are not always so plentiful and desirable, there being but a limited number of species or varieties that withstand either excessive heat and drought, or the other extreme. In any case it behoves us to prepare for the worst, and then whatever comes there will be the comforting reflection that we at least have done our duty. As it happens, the little extra trouble taken in preparing ground for crops known to be most serviceable during a hot or dry season will not in any case be altogether thrown away, good culture being with few exceptions invariably attended with excellent results.

VEGETABLE MARROWS are undoubtedly the most serviceable hot-weather crops that can be named, and there are times when little else in the way of fresh green food is to be seen in Covent Garden and other markets. They are sent in huge wagon loads, and sell readily at remunerative prices. Added to this, they are quite the sort of vegetable that one likes during hot weather, and at all times are appreciated by most people. The weatherier classes perhaps are not particularly fond of Marrows, but they would like them better and order them oftener if they were cut in a small state or before the seeds develop and cooked whole. It is when thus treated that they are rightly termed Vegetable Marrow. If my advice, therefore, is taken, they will be more extensively grown than usual this season. There is no necessity for, nor wisdom in, making elaborate preparations for this crop, those huge heaps of decaying matter with a little soil on the top, which are too often provided for Marrows, invariably promoting a rank, unprofitable growth. They may perhaps be needed in very cold districts, but even of this I have my doubts, as wherever I have practised gardening by far the best crops have been had from plants growing under apparently less favourable conditions. If sheltered corners in a yard or some kind of a little space that can be well spread for Marrows, then, instead of using so much rich manure and do-

caying vegetable matter, be very sparing of the former and substitute more common garden soil, or say to the extent of at least one half of the bulk. Where they really exceed the best in the open garden with a row of Runner Beans or rows of Peas on the north side. Open a trench 4 feet in width and 6 inches in depth, throwing the soil evenly on each side. Then wheel in a layer about 1 foot in depth of only partially decayed stable-manure, or a mixture of this and leave, returning the greater portion of the soil thrown on to the top of this, and no further preparation is needed. Sow the seed at once where the plants are to grow in patches 3 feet apart, and by the time the seedlings come up no protection will be needed. Not more than one plant should be left at each station. This is the market grower's plan, but most private gardeners can afford time and space to raise the requisite number of plants under glass. Sow during the first week in May singly in 3 inch pots, and harden and plant out before the seedlings become stunted. Too often they are raised three weeks too early, and rather than put out starvelings I would prefer to raise a fresh batch. Plant in a single row through the

Pen "No Plus Ultra."

middle of the raised bed, disposing the plants 3 foot apart, and roughly protect from frosts and winds. In dry weather it may be necessary to water occasionally during the first month, after which they may safely be left to take care of themselves, the plants bearing profusely in hot, dry weather. Never pinch or prune, but let the plants grow, spread, and fruit naturally.

SPINACH usually fails in hot, dry weather, but if seed is sown on a cool north border previously well prepared by manuring and digging the crops hold out surprisingly well. I prefer the Victoria or Monstrous Virolay for summer and early autumn crops, this standing much longer than the common round-seeded or summer Spinach. About three sowings at fortnightly intervals should be made, commencing towards the end of May. The drills ought to be drawn 1 foot apart and be moistened if at all dry prior to sowing the seed. Thin sowing should be practised and thinning out where needed early reported to, crowded Spinach being the first to go to seed. A fairly good substitute for the one Spinach is found in the New Zealand Spinach, though it is my belief the greater

portion of what is annually grown in this country is never used. This species, being of a succulent nature and somewhat resembling the common Ice plant, actually revels in a hot and dry position, though it ought to have a good thickness of decaying manure under it. A dozen plants will yield abundance or a sufficiency of young tops or shoots, these being what are boiled for most establishments, and they should be planted or sown on a south border or other sunny position fully 3 feet apart each way. The requisite number of plants may yet be raised under glass singly in 2 1/2-inch pots, or the seed be sown in the spots prepared in the open. The plants require no watering after they are once well established, but should be protected from frosts when first put out and again in the autumn.

TOMATOES are essentially hot-weather vegetables or salad as preferred, and for these the weather cannot well be too hot and dry. Should we experience a hot season the demand for Tomatoes will exceed anything that has previously taken place in that way, and both private and market growers will do well to plant extensively. Unfortunately, open-air crops are most precarious, but then they can be cultivated where nothing else will or is often grown, and not unfrequently heavy crops have been taken from plants growing in the open borders, these being supported by strong stakes. The sites I can most strongly recommend are sunny garden and house walls, those that screen the plants from rainfall being much the best. If the foliage can be kept fairly dry it is not often that the disease spoils the crops. Give each plant the benefit of a good spit of fresh loam and half that quantity of manure, and they will then grow healthily and strongly, producing heavy crops without much further trouble beyond removing all superfluous side-shoots, and securing the stems to the fence, walls, or stakes, as the case may be. Open Air and Earliest of All are among the first to give ripe fruit, while Conference crops the most surely, such sorts as Dodham Favourite, A 1, and Perfection also doing well.

RUNNER BEANS, though moisture-loving subjects, will yet do remarkably well in a hot season, provided they always receive abundance of water at the roots. The rows of these, then, ought to be located conveniently near a good water supply, and a thorough soaking should be given at least once a week during a dry season. Dribblers are simply thrown away on them, and if the plants fail to set great clusters of pods, this is proof positive they are too dry at the roots. They like plenty of manure, too, and in addition to digging in a good dressing of solid manure, liquid manure ought also to be given freely. Allowing them to mature a quantity of seed has a very weakening effect, and the pods should be kept closely gathered whether wanted for home use or not. Kidney Beans are never continuous-bearing for any great length of time, but they can be had throughout a hot season by sowing at short intervals, the ridges between Celery trenches answering well for them.

PEAS are not happy during very hot and dry weather, but even these succeed surprisingly well on spaces 6 feet or rather less in width between Celery trenches. They also do well if treated as liberally at the roots as runner Beans. No Plus Ultra (see cut) is one of the best hot-weather varieties that can be tried. Cabbages are usually too much over-run by caterpillars to be of any real service, and the same remark applies to the earlier varieties of Cauliflowers; but the Autumn Giant can be had clean and good in August, provided the plants are kept well supplied with moisture and manure at the roots. I.

3990.—Early Potatoes.—Let the tubers remain in the ground until the haulm dies completely away, then lift the crop, choosing dry weather, if possible, and let the tubers lie out in the sun for two or three days until they become slightly green; then stow them in a dry place, laying them out thinly, and look them over occasionally to remove any diseased ones. The great thing is to get them thoroughly ripened or matured.—B. C. R.

3991.—Medium-sized tubers from the most prolific roots for planting next year if you wish to have a good crop. Dry them by exposure for some time in an open shed, not exposed

to bot sunshine, and then pack them away in shallow boxes in some building where the frost cannot reach them. If this cannot be done at once cover with straw and earth till winter. But before the eyes move lay them out thinly in a light position to develop the crown eye. One stem is enough for early Potatoes.—E. H.

— Do not dig up the Potatoes until the tops are quite dead. Choose a dry day then for taking up the tubers, lifting them carefully without bruising the skin. Spread them thinly out in a cool, airy shed for two or three weeks, and afterwards store them in a cellar or dry room in a heap, box, or barrel. Examine them occasionally during the winter to make sure that none are decaying; if so, remove such to prevent their contaminating the remainder. Rub off any sprouts that may grow until the early part of February, when the tubers should be set on end in layers in shallow boxes, and be placed in a light and cool room free from frost to induce the sprouts to grow strong. These latter should be about $\frac{1}{2}$ inch long at planting time.—S. P.

4001.—Unsatisfactory Cucumbers.—The plants have got "warty roots," and for this affection there is no positive cure, so far as I am aware. You may try watering them with soot and lime-water, however. The best plan will be to pull them all out, and plant another batch in entirely fresh soil. If only a little of the old soil is left the disease will reappear.—B. C. R.

— Want of moisture, stimulative food, and overcropping are the main causes of the fruit turning yellow at the points. When Cucumbers have been in bearing some time the soil becomes poor, and the plants are in consequence exhausted of their energies to go on producing fruit abundantly. They need invigorating to induce them to make new growth, and consequently fresh fruit. Thin out the old and worn-out shoots and decayed leaves. Cover the surface-soil 2 inches thick with a compost of partly-decayed horse-dung and fibrous loam in equal parts. If neither of these can be obtained give the surface-soil a sprinkling of Clay's Fertiliser or dissolved bones, and cover it with road-scrappings. Afterwards give a thorough soaking of tepid water—certainly not less than 90 degs. Syringe the foliage thoroughly early in the morning and again in the afternoon about four p.m. Supply abundance of water to the roots when required, but on no account give sufficient to create a stagnation about the roots, or the fruit will again turn yellow. The best plan to ascertain if water is needed is to dig down in the bottom of the bed to see what state the soil is in. Too much moisture is almost as bad as too little.—S. P.

— The Cucumbers are affected by a very troublesome disease, and the only remedy is to clear out everything, and start again with young plants from a fresh source.—E. H.

4006.—Tomatoes not setting fruit.—No one can say that the present season has been unfavourable for the setting of the fruit of Tomatoes, for we never had a more favourable time so early in the season. That being so, it is quite clear that your treatment is wrong. I should say the soil they are planted in is too loose, and that they have had too much water. Tread or ram the soil firm about the roots, and give them less water until some fruit is set. Beginners in Tomato culture should grow their plants on in 7-inch pots until the first bunch of flowers have set their fruit, and then plant them out.—J. C. C.

— As the plants are healthy and strong they ought to do better; but you must consider that this is exceptional weather, and I think a light overhead syringing once, or even twice, daily on very hot days will help you considerably. Also dissolve a very little sulphate of ammonia in the water given to the roots only occasionally.—B. C. R.

3951.—Cardoons.—It is late now to sow seeds of Cardoons; it should be sown from the middle to the end of April. A good plan is to sow a few seeds in the centre of large 60-sized flower-pots. One plant will be enough; remove the others. When they are large enough for planting they must be set out in Celery trenches; but there ought to be a space of about 2 feet between the plants, and 5 feet at least between the rows. The plants need plentiful supplies of water in dry weather, and by September and October they are ready for earthing up. Tie the leaves round with haybands to keep them together, and earth must also be applied over them. The operation of earthing up should be done on a dry

day. The French Cardoon is not so good to grow as the spineless-leaved Spanish variety.—J. D. E.

3997.—Climbing Peas.—There are many acres of Peas grown in this neighbourhood, but none of them have sticks put to them. The farmers take a hook and switch the tops off, because they say it does not pay to stick them. They only get two gatherings from them, as the tops being cut off stops the formation of pods near the top of the plant. For garden purposes it is better to stick the Peas, as they certainly do better, larger crops are produced, and in succession.—J. D. E.

— Doubtless Peas may be grown without sticks by pinching in and the points of the shoots bent. If tall Peas were operated on in this way the crop would be very light.—E. H.

— Do not by any means prune the Peas in the vain hope that greater produce will be the result. If extra large pods are required, the pods may be pinched out of the haulm to prevent other pods forming, but this is at the expense of a full crop.—S. P.

INDOOR PLANTS.

TINNEA ÆTHIOPICA.

This is the name of a plant of which "T. Marchant" sends me a few sprigs, saying—"They are the last of a plant that has been flowering since the month of January, and filling the house with the fragrance of Violets." This plant is one of those collected in darkest Africa by the celebrated Mlle. Tinne, whose father was engaged in some business in Liverpool, in which place it was raised, and it was in the winter of 1866 that I first saw the plant flowering beautifully in Mr. B. S. Williams' nursery in Upper Holloway, and through which firm it was distributed to the public, and I am very vexed that it appears to have fallen out of repute so much, for it is now a long time since I saw the plant. This plant was gathered by two celebrated travellers, i.e., by Captain Grant, during his journey in company with Captain Speke, and by the celebrated Doctor, but now Sir John Kirk, then attached to the Livingstone Zambesi Expedition. And these gentlemen, I think, had become possessed of the plant before Mlle. Tinne found it. These being sent to Vienna were worked up by Dr. Kotchy and at once named, so that is how the plant became known by the name of Tinnea. It is a plant belonging to the order Labiate, which would not convey an idea of its lasting so long in flower. It is not a gay plant, but its lovely odour makes amends for any lack of brilliancy in the colours, and it may be grown to any size one likes; either in the shape of large bushes, 6 feet in height, or in small twiggy bushes of about one foot; the larger the plant can be grown, of course, all the more imposing does it become, and the wider is its delicious perfume diffused. The plant requires the warmth of the stove and plenty of moisture to maintain its leaves, which are small and entire, of a deep bright-green on the upper side, paler below. The flowers are borne upon short spikes, usually in pairs, and in great abundance. The flower protrudes from a large green calyx, and is of an intense deep maroon-purple, yielding a powerful odour of Violets, which makes it doubly welcome, flowering in the dull days of winter and the early spring. It is a plant that does not require a large pot, but the one it has should be well drained, and the soil should be composed of loam, peat, and leaf-mould, made sandy, and the plant should stand in an ordinary stove, with a temperature which does not fall below 60 degs. at any time in the year. There should be a nice moist atmosphere maintained during the growing season, and at no time must it be allowed to suffer for want of water. Treated in this manner Tinnea ethiopica will yield the household a delicious perfume of Violets for a long time, and cutting it does not mutilate it, if the cutting is done with reason. J. J.

3994.—Plumbago capensis.—I put cuttings of this creeper, about six, in a 5-inch pot, in a mixture of loam, leaf-mould, and rotted manure; when rooted each of these is planted in a separate pot of the same size, and by the following year it can be trained to a 3 foot stick, and about the middle of June is in flower. To make a handsome plant for the conservatory set a box 2 feet long, 1 foot deep, and 1 foot wide, with holes for drainage bored in the

bottom. Put in first about 2 inches of crocks, then a layer of turfs and fill up with the same mixture as mentioned above; put a single plant in the centre and on each side one of the varieties of Ribbon Fern. The Plumbago may now be trained on a wall or trellis, and when two years old will have grown some 8 feet to 10 feet and be covered with bloom. Attention to watering is the main thing with Plumbago. It should never be allowed to want moisture.—A. G. BUTLER.

— This is really a very vigorous growing plant, and would not be likely to do much good in a 7-inch flower-pot; in fact, the best results are obtained by planting it out in a border of good soil, and allow it to take the character of a climbing plant, growing freely and flowering profusely as it always does. I should replot the plant into a 9-inch or 10-inch flower-pot, using good yellow loam, decayed manure, leaf-mould, and sand. A little fibrous peat is useful to keep the compost open, and the roots run freely into it. It is strictly a greenhouse plant.—J. D. E.

— The plant will flower presently, no doubt. You may sprinkle a very little Clay's fertiliser on the surface of the soil in the pot, pricking it lightly in, and then giving a good watering; but this is a very powerful manure for such delicate-rooted subjects. I should prefer to water the plant with weak soot-water now and then, and give it also a weak solution of sulphate of ammonia or urtrate of soda every other week. Do not pinch the shoots any more this season. A good sandy loam suits this plant better than anything else.—B. C. R.

— The Plumbago succeeds well planted out, and will thrive in either a greenhouse or conservatory. But the finest results I have seen with this plant have been when it is planted out in a border in quite a warm conservatory, the branches being smothered with the lovely pale-blue flowers. There is a variety named alba which has, as its name suggests, white flowers, borne with the same features in the type. It would be better to plant out the Plumbago in the house, and prepare a well-drained soil, and for pots it is also useful. I used to have a lot in 8-inch pots, the soil kept moderately dry in winter. The growth in spring should be cut back, and the plants repotted. Pinch the shoots when they have grown about 3 inches in length to promote a bushy habit. It is very easy to strike cuttings in the spring, and treat them similarly to those of the Fuchsia. A very pretty effect is gained by associating the type and the white-flowered variety.—C. T.

— The pot, a 7-inch one, is small for a 2 foot plant; this would account for the smallness of its leaves. If a larger pot is given a greater crop of flowers will be obtained after a while, but not so soon as though it were allowed to stay in the same pot it is now growing in. If you have space for a large plant I should advise that it be repotted into one 10 inches in diameter, employing a compost of three parts loam, one of peat, and one of leaf soil, with sufficient sharp silver sand to keep the whole porous. Well drain the pot and allow a full 1½ inch space at the top for water, as this Plumbago enjoys abundance of water at the roots. When the pot is full of roots occasional doses of weak liquid-manure will be an advantage. Well syringe the foliage every evening as a preventive of red-spider, to which this plant is liable. If the plant remains in the same pot half a teaspoonful of Clay's Fertiliser sprinkled over the surface once a fortnight and watered in will assist the growth. Do not stop the shoots in any way. Allow them to grow away at will, as it is from the ends of the shoots that the bloom spikes appear.—S. P.

4000.—Zonal Pslargoniums.—The largest plants should be potted in 6-inch pots, the smaller in 4½-inch, in a compost of three parts fibry loam, one of leaf soil, and one quart of bone-meal to every bushel of the compost. Pot the plants firmly to induce short-jointed growth that will mature as it progresses. From the best prepared plants of this character the finest blooms will be had. After potting, the plants should occupy a cold frame until the roots are running freely in the new soil, when a position fully exposed to the sun will be the most suitable. A thick bed of coal ashes provides a cool base for the plants to stand upon during the hot summer days. Continue to pinch out the point of each

shoot when 3 inches of new growth is made to induce other shoots to push from below, so that stocky as well as bushy plants will be provided, as these, of course, give the greatest quantity of bloom. When the pots are full of roots give the plants occasional soakings of liquid-manure, made from cow or sheep-dung, adding a little acet. When the buds are visible a quarter of a teaspoonful of Standen's manure spread over the surface of each plant, washing it with clear water, will stimulate the growth and assist in the development of the flower-trusses. Six weeks before the plants are required to be in bloom the last stopping of the shoots should be made. The following dozen are excellent sorts: Lord Rosebery (brilliant crimson), Lord Salisbury (rich madder shade of scarlet, tinted magenta), Golden Veuvius (orange-scarlet), Marquis of Dufferin (crimson magenta), Lady Reed (white, scarlet centre), Mrs. Robt. Cannell (deep salmon), Olivia (a pleasing shade of salmon), Mrs. David Saunders (pink), Swanley Single White (pearl white), Sir Fenshal (white, large truss), Amphion (deep-pink), Mrs. Strutt (rose-pink).—S. P.

I grow a span-roof house full of these plants for winter flowering. The cuttings are put in, one in the centre of a small sixty-sized flower-pot, about the middle of the month of April. The cuttings are taken from the plants that flowered the previous winter, and as they are generally out-of-doors by that time, the cuttings are hardy grown and do very well in cold frames; they mostly all form roots. When well established repot them into what are termed small forty-eights; these are 4 inches diameter inside measure; after a time they are planted in 8-inch and 7-inch flower-pots, and in these they produce their flowers. The Zonal Pelargonium does not require very rich compost. Pot them in five parts loam, one of leaf-mould, one of decayed manure, and a little sand. The plants are grown out-of-doors from May to the end of September. A few good varieties are as follows. Crimson and scarlet shades: Lord Salisbury, Lord Rosebery, Miller's Favourite, Duke of Fife, Swanley Gem, Brilliant, Edith Pearson, and Mr. H. Cannell. Pink and rose tints: Edith Miller, Constance, Mrs. Struth, Mrs. Wildsmith, Edith George, and Mrs. David Saunders. Of white varieties: Swanley Single White, Queen of the Belgians, and Queen of the Whites Improved. Salmon tinted: Lady R. Churchill, Beauty of Kent, Opal, Mrs. Norman, Lady Rosebery, and Perdita.—J. D. E.

If in stove-pots, as they appear pot the cuttings off singly at once, and keep them in a cool, shady house or frame until rooted and growing. As soon as possible shift them into 5½-inch or 8-inch pots, and when established stand on saucers in the open air, choosing an open and sunny spot. Give just enough water to keep the foliage fresh and the plants growing slowly, and pick out all flower-buds until the middle or end of September. House early in October, and in a light, warm house the plants (if of suitable varieties) flower freely during the greater part of the winter.—B. C. R.

A note upon Anemones, &c.—Anemones or Windflowers are of many kinds. The frail little Wood Anemone that seeks shelter in our English woods is represented in gardens by many exquisite varieties, the sky-blue Robinsoniana, a delightful shade of colour, and the double white being amongst the more charming, especially if grouped at the foot of a tree. The Blue Winter Windflower, (A. blanda), the Apollonia Windflower, and the Hepaticas, H. angulosa are good garden flowers. A. blanda blooms, quite early in the year making rich masses of leafage, against which the blue flowers are in fine contrast. All require a light soil and to be kept free from damp. The novice in gardening would first choose, possibly, the Hepaticas, glorious old English flowers that seem to have an enduring interest. They are amongst the first flowers of the year. The Hepaticas are quite hardy, but often get killed in very damp soil, conditions which do not in the slightest agree with their somewhat fastidious constitutions. Roots are not set deeply down, but a well-prepared soil is requisite to gain the best results. The reason why Hepaticas fail is in many cases due to over-watering and disturbance at the root, which is sure to kill them, as no plant perhaps resents interference

so much as this species of Anemone. When planted late then remain until they have grown into broad, handsome clumps, which, if thought necessary, may be divided. An open sunny bank, border, bed, or conspicuous positions on the rockery suit well the Hepaticas, of which there are many varieties, as the single blue, red, and white, with double forms of each kind. A. angulosa, called the Great Hepatica from the size of its sky-blue flowers, must not be overlooked. The beautiful Snowdrop Windflower (A. sylvestris), the Pasque-flower (A. pulsatilla), and the lovely Windflowers of Japan. A. japonica should have a place in the amateur's garden. A. japonica and its white variety alba, or Honorine Jobert, are amongst the finest of hardy perennials, bold and handsome in the border, and of value for cutting. They enjoy a deep, moist soil, and an occasional mulching to established beds will do no harm. A thriving clump of the white variety when in full flower is a splendid picture, especially if backed with green foliage, to bring into full relief the purity of the blossom. It is best, to increase the stock, to divide the roots, and every particle will grow. The Scarlet Windflower (A. fulgens) and the beautiful Poppy Anemones may also find a place in the beginner's garden. The Poppy Anemone gives one a gay variety of colours, and is easily raised from seed sown in the month of April or June on good, rich, well-prepared soil.—C. T.

FERNS.

3944.—**Ferns and out-flowers.**—Most of the Pteris family last better in water than the Adiantum, Pteris cretica and Pteris tremula being two of the best. But they do not give such a good effect as Maiden-hair, which is unique in this respect. Ferns last better with out-flowers when they have been placed in a bath of water, frond and all, for a few hours, so as to be thoroughly wet all through, the fronds being full grown, and out from a well-hardened plant. Some of our English Ferns are very useful with out-flowers, Asplenium Adiantum-algum (the Devonshire black-stemmed Fern) being very elegant, and small enough for specimen glasses. Small fronds of the common Athyrium too, will often last a long time, if carefully cut; but they will not take up water if the stems should be torn and bruised by the hand. Asparagus plumosus stands well in water, and is the most graceful substitute for Maiden-hair Fern, and the leaves of the Common Yellow Fumitory are so similar that they are sometimes mistaken for the Adiantum Capillare. This Fumitory should be grown for its foliage.—I. L. R.

BIRDS AND INSECT PESTS.

SELDOM have small birds appeared more in the light of friends of gardeners than during the exceptional drought that has prevailed for the past three months, for a protracted spell of warm, dry weather favoured the early advent of swarms of grubs, caterpillars, and fly of various sorts and kinds; they live on the leaves or tender shoots of fruit-trees, flowers, etc., and unless small birds had come to the rescue I fear that many gardens would have been well-nigh defoliated by this time; but, owing to the exceptionally dry season and scarcity of other food, many kinds of small birds have lived almost exclusively on grubs, caterpillars, green and black-fly, etc. For some weeks past I have watched the common house sparrows lately hanging on to the shoots of wall fruit-trees, busily picking off the fly from the under side of the foliage, and different kinds of finches have been equally active, and I have tried caged birds by putting in shoots covered with fly, and they have set to work and cleared them off rapidly; in fact, my impression is that the amount of good done by birds—that are by many looked on as the natural enemies of gardeners—far outweighs any mischief they do at other periods of the year, and I think that if the destruction of small birds were carried too far we should be far greater sufferers from the attacks of insects and other pests than we are now. Such exceptional seasons as the present upset many of our calculations, but it is gratifying to note that birds are doing their best to mitigate the effects of the drought by persistently attacking the worst enemies we have to contend with.

A FEW GENERAL NOTES.

GREENFLY.—In a small house this can be kept well under limits by using a dry paint-brush, such as can be had for 3d. or 4d.; hold the pot in left hand on its side, brush upwards firmly but steadily. Let the aphids fall on the ground; they are then harmless. Last winter I kept 40 Pelargoniums free from fly by brushing once a week. It took about 30 minutes to do. Amateurs so often fail when syringing, either over or underdoing it. The dry brushing is simpler.

ANTS.—It is a mistake, with all due deference to many writers, to suppose that ants are only after insect life, and that they will not attack plants. Recently I had a Tritonia bloom-stalk eaten through by small ants. They simply cut a deep, wide incision across the stalk, so as to kill the bloom. Tritonias are known to stupefy bees in ordinary seasons, and perhaps our long period of hot weather had caused an unusual amount of saccharine matter to develop, thus attracting the ants.

TOMATOES can be grown perfectly well under Vines if placed against the glass at bottom. I always grow enough for home use in boxes in this way; I also grow three or four Cucumbers the same way, and last season I kept the table supplied three times a week for three months. Lookle and Telegraph were the kinds used.

TROPEOLUM SPECIOSUM.—An experience of over twenty years has told me that this, one of the most beautiful and effective of its class, is also one of the most uncertain things to grow. If the conditions are suitable it comes up like a weed, running up many feet from the parent. I have grown it in Scotland and Ireland to perfection in a full southern aspect, and not at all moist ground, notwithstanding these facts are supposed to be hostile to its growth. Here, in Jersey, I have tried it under all possible conditions, but without success. It is alive but does not flourish, and everyone else I hear who has tried it in the island has equally failed.

MUSCAT GRAPES ripen and colour perfectly in a cold house, provided they get plenty of daily sun and air, and that the night temperature does not fall below 50 degs. I do this yearly, and so do many others. They must hang until well on in September.

"NOBLE" STRAWBERRY.—I was surprised to see this variety condemned in GARDENING. For house forcing and for earliest outdoor fruit there is more "Noble" grown here than any other kind. It may not have the high flavour of some other varieties, but for size of berry, fine colour, and enormous productiveness, we consider it hard to beat. This year "Noble" ripened in the open, and of April, and I weighed some fruits which exceeded 1 oz. each.

4002.—**Paraffin-oil and water for plants.**—I have seen so much injury done to trees and plants through the use of paraffin for the purpose of destroying insects that I advise you to look for a less destructive remedy. Within a mile of where I write I could show this correspondent some young Peach-trees with scarcely a leaf upon them. The same trees started well in the spring, and had set a good crop of fruit. They were, however, attacked with green-fly, and in an unlucky hour the owner syringed them with paraffin and water to destroy the insects, with the result that he has lost his crop of fruit for this year and probably the next. In the hands of careful people paraffin is a capital insecticide, as when sufficiently diluted it will not injure even the delicate fronds of Ferns. To make it safe the quantity is so small that amateurs cannot believe that there is enough to do any good. Therefore, my advice to them is—that they have nothing at all to do with it.—J. C. C.

—Paraffin-oil and water will not mix thoroughly, and this forms a great drawback to its use; otherwise, it is a valuable cleanser. If used at all, water and oil should be kept in a state of agitation, and therefore it would not be suitable for dipping plants in, as the oil of the mixture if quiet for only a short time would float to the top of the water. I have used it occasionally mixed with water at the rate of ½ pint to 4 gallons of water. But if used at all, it is best to mix it with soft-soap, blending the soap and oil together well before adding it to the water. From 1 oz. to 2 oz. of soap to the gallon will improve the mixture as an insecticide.—E. H.

FRUIT.

THINNING FRUITS.

This is a work that will need more than usual care this season—at least, if the blossom has set so regularly in other places as it has done here; yet it is a very pleasant and profitable work, as the fact of having to thin proves that the season has, thus far, at least, been favorable to the early development of the fruit-crop, and our proverbially fickle climate has been for once inclined to conditions so closely bordering on "set fair" that the danger was really getting very imminent that we should suffer from too much fine and cloudless weather. Rain fell a while ago, but in only slight quantities compared with what heavily-laden fruit-trees require, and unless we get much heavier rain the crop will need thinning even more severely, for fruit is so largely composed of water that it needs little argument to prove that anything approaching drought must materially reduce the weight of the crop. Thinning fruit is by no means a new thing; but, as a rule, it is confined to fruit grown under glass or on walls. No one would think of letting their Grapes or Peaches go unthinned, yet little attention is paid to hardy fruits, although my idea is that a good crop of Apples, Pears, or, in fact, any kind of hardy fruit yields more profit than the hot-house grown crop, for it is only what is left after the expenses of production are deducted that can be set down as profit, and we all know that hot-houses are expensive things. Taking hardy fruits in order of merit, I have no hesitation in placing before all others—

THE APPLE.—Look at the enormous and ever increasing demand. Why, with all our improvements in culture and modes of keeping the fruit late we are still dependent on imported fruit quite six months out of the year, for Apples are always in demand, and if the public cannot get home-grown samples they will have the imported ones, and the price that has been paid for months past for boxes and barrels would convince any unprejudiced person that Apples are a profitable crop; but they must be good, and the only way to get them really fine is to thin out the clusters to one, or, at most, two fruits each. Other details of culture must, of course, be of the best, but on the thinning of the crop depends the size of the fruit.

PEARS are fruits very liable to set in clusters, and the value of Pears is more dependent on size than almost any fruit. I do not suggest that it is necessary to rival the Jersey-grown fruit, but there can be no doubt about good large samples selling freely, when small, under-sized fruits are a drug in the market. Kitchen Pears pay as well for severe thinning and high culture as any of the first-class dessert sorts.

PLUMS of good dessert sorts repay thinning well, for in a season like the present, when fruits are set very plentifully, anything in the way of overcropped trees will only produce samples that must be sold at so much per bushel, but extra fine fruits fit for setting up in preserves, and sold at so much each, are the ones for profit or pleasure.

GOOSEBERRIES may be thinned out by picking the green fruits for tarts while quite small, leaving only the best placed fruits to grow on for dessert.

STRAWBERRIES are, as a rule, thinned severely when grown in pots, for as soon as enough is set for a crop all the rest are clipped off. Surely the same attention would be amply repaid with outdoor crops.

MULCHING AND WATERING should be done conjointly with thinning, for as soon as the tree has got only what fruits are expected to come to maturity set out, every effort should be made to swell up these to their fullest extent; therefore, mulch over the roots, and water copiously over the mulching.

J. GROOM, Gosport.

3088.—Peach tree branch withering.—This is usually caused by what gardeners term gumming. An exudation of sap takes place at a certain point in the branch, which gradually hardens, and the branch dies from this point. It does not matter where the tree grows, as the

disruption of the sap vessels takes place anywhere; sometimes on wall trees, and at other times when they are grown in a forcing-house. There is no cure for it, but it can be prevented by keeping the roots of the trees in good soil and near the surface. The leaves of the trees must also be healthy, and free from all kinds of parasites, such as mildew and insect pests.—J. D. E.

— There is nothing very unusual in this, especially in the case of old trees. At the same time it is perplexing to see them do so while other parts of the tree remain perfectly sound and healthy. I have examined many such branches without being able to trace the cause clearly. I am, however, inclined to think that it is the result of an injury while the branch was quite young, such as a bruise by a cuckoo from a hammer, or the undue pressure of a nail, which brought on a kind of canker.—J. C. C.

— If "E. G. W. P." will examine the branch at the base of where the leaves show signs of withering it will be found there is a wound; most likely gum will be oozing out of

Fruiting-branch of Kelsey Prune.

the bark, hence the cause of the leaves withering. There are a variety of reasons for premature decay of a part of a tree. The main one is that the bark has been injured while in a young state, most likely by the ligature supporting this particular branch being made too tight, which prevented the bark expanding regularly, thus causing a wound. Overcropping will account for a withering branch, and so will having the roots too deep in a cold subsoil. The first, though, is the most common cause of Peach-tree branches decaying prematurely. There is no cure for it now that decay has set in.—S. P.

— Peach branches may die from one of several causes. The branch may have received some injury, or it may arise from gumming or canker, or the tree may be in weak health, and the dead branch may be the first indication of the coming break up. It is not usual for the branches of healthy trees to die in the same way as the branches of Apricots die off. If the tree is healthy young branches will soon fill up the space left vacant by the removal of the dead branch. Overcropping ruins a good many Peach-trees.—E. H.

3089.—Blight in Apple-trees.—The "American Blight" is easily destroyed by a mixture of soft-soap and kerosene well rubbed into the affected parts with a

shaving-brush. You should not neglect to prune the tree if you wish to get a good crop of Apples.—A. G. BUTLER.

— The trees are attacked with the "American Blight," which eats its way under the bark, causing wounds, and if not checked will eventually kill the trees. The present is not a good time to cleanse the trees of this pest, but it may be kept in check by well syringing the trees, thoroughly wetting the affected parts with a strong solution of Stott's Killmright. First cut away all useless shoots of the current year's growth, as this will enable the liquid to better act upon the blight. When the leaves have fallen prune the trees carefully, and thoroughly scrub with a hard brush a solution of Fir-tree-oil or pure methylated spirits the parts affected, repeating the operation again in a month. If any of the insects appear the following year touch them with a small brush dipped in Fir-tree-oil, mixed with water as directed on the vessel containing it, as bought from any seedman.—S. P.

— This is certainly the "American Blight." The white fluffy stuff is the protecting material over the insect which does the mischief (Aphis isuligera). It would certainly in time kill the trees if not destroyed. There is no better way to deal with it than to take a small pot of paraffin and apply it just as it is, undiluted, with a brush. The liquid penetrates into all the cracks and crevices, destroying every one of the insects. The pest attacks the branches first, but will in time descend to the roots, where it seriously hampers the growth of the trees.—J. D. E.

— "American Blight" may be got rid of by perseverance if the trees are worth saving. There is no better remedy than soft-soap, made into a strong lather and brushed well into the cracks and crevices where the insects are laid up.—E. H.

THE KELSEY PRUNE.

In reply to "J. R. S.," this is a very fine Plum, largely grown in California. We should be glad to hear from anyone who has grown the Plum in this country as to its hardiness and productiveness.

STRAWBERRIES IN POTS.

With regard to sorts of Strawberries to grow in pots, opinions differ greatly as to which are the best. Almost every grower has his favorites, but there can be no question, I think, as to the great superiority of British Queen, if size and flavour are taken into consideration. Unfortunately, British Queen will not succeed everywhere, and many have a difficulty in growing it, as it requires a good, rich, and moderately light soil, and even then it is apt to be barren and go off. With me it does well, and is the chief kind I cultivate. In cases where the Queen fails or is not satisfactory, I would advise Sir Joseph Paxton to be substituted. This possesses many good qualities, as it has size, firmness, high colour, and excellent flavour. President has long been a favourite with many and is a prodigious cropper, as it flowers abundantly, sets freely, and the fruit swells regularly and colours up well. Sir Charles Napier is valued by market-growers, as it is a robust free growing variety, but though showy and taking to look at, it is not of high quality. Auguste Nicaise has during the last year or two come under notice, and just lately a dish of fruit of it exhibited caused quite a sensation, as each fruit weighed over 2 oz., and it is a fair flavoured kind. The above-mentioned are all second earlies, therefore, for first crop forcing it is necessary to have some other sort, the most precocious among those known being Noble, which ripens at least a fortnight before any other I have yet tried in pots. For freedom of growth, setting and cropping, Noble is quite unsurpassed, the fruit being large and very showy, but the flavour is flat, or it would be the most valuable kind in existence. The one I depend chiefly on is Vicomtesse, but it requires good cultivation, and to be satisfactory the plants must be strong. If they are, they send up fine heads of flower and produce large, firm, rich, bright-looking fruit that packs and travels well without being injured or bruised. In forcing Strawberries, however, it is not advisable to have many varieties, but to stick to two or three that are found to suit, as then a mere regular supply can generally be maintained and the trouble entailed in their preparation and management.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, notes, and notices vary so infinitely that general answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4027.—Early Fuchsias for window culture.—Wanted, please, the names of the three earliest-blooming Fuchsias for window culture.—C. N. P.

4028.—White-flowered plants for cutting.—What is the best white-flowered plant for cutting from to come into season just before the Plinks?—C. N. P.

4029.—Blood-manure, &c.—Will someone kindly tell me how to make blood into dry manure with some salts, and how to dissolve boeset?—ALBERT GARDNER, Hill

4030.—Fraxinea ramosa.—Will somebody kindly tell me what treatment is required to grow Fraxinea ramosa (Bridal Wreath), and when is the season for flowering?—ENQUIRER.

4031.—Monthly Rose.—Will someone kindly inform me if the old-fashioned Pink Monthly Rose is suitable for juggling down, or if it flowers better when left to grow naturally?—SERA.

4032.—Cut flowers.—I have got plenty of plants in bloom to cut from just now except red. What can I grow to give scarlet, crimson, and pink shades outdoors in early June? Locality, Wolverhampton.—C. N. P.

4033.—Sempervivum tabuleforme.—Is this hardy or tender? I have a plant—or rather eight or nine plants—in an 8-inch pot, which does no good, and I should like to know if I can plant it in the garden?—C. N. P.

4034.—A Privet hedge.—When is the best time to cut down a Privet hedge two years old with a view to strengthening it? It gets killed every winter—that is, some of the stems—and it is, in consequence, very thin. Can I put in cuttings at the bottom? If so, when, please?—C. N. P.

4035.—Lilies and Irises.—I am anxious to plant a border for next year with lilies and Irises. I faced south, with a brick wall at the back; soil, clay and loam. Would anyone kindly tell me the names of some of the best Lilies (coloured and white) and Irises? I should like as many as possible to flower in the summer.—PAUL PAV.

4036.—Plumbago alba.—I have a very flourishing plant of Plumbago alba on my greenhouse roof, growing in large pots. Will some tender kindly suggest a plant to replace it to give white cut flowers? The Plumbago blooms are too perishable. All kinds of greenhouse stuff flourish, and the house is moderately heated in winter. Lean-to, 13 feet by 9 feet; aspect, west.—C. N. P.

4037.—Treatment of an Apricot.—Thanks to your good advice, I have for the first time nice Quinces and a good crop of Apricots, so trouble you again. A Pear-tree against a south wall planted about six years back makes vigorous growth, feng shoots; hitherto I have cut them off. Tried root-pruning by cutting a trench about 14 inches from wall. Gull the same luxuriant shoots and foliage, but no blossom even. What is best to do with it?—G. C.

4038.—Manure for Chrysanthemums.—In a recent number of GARDENING I notice that pigeon's manure is recommended for Chrysanthemums, to be used in a liquid state. Would dove's manure answer the same purpose, and would the corn accidentally mixed with it make the water in any way injurious to plants? The doves are kept in a large cage, and have plenty of grit, water, &c., and are quite healthy.—ENQUIRER.

4039.—Management of a greenhouse.—I should be very much obliged if anyone would suggest to me any means of getting over the following difficulty:—viz.: A friend of mine, who has a greenhouse some 30 feet long, required the top shading last summer, and ordered one of his men to do so, but who foolishly coated it with ordinary green paint. The consequence is that everything has since died through the house, but I had, of course, the paint has got such a hold on the glass it seems impossible to get it off. If you can give me any assistance as to removing it I shall be very thankful.—A CONSTANT SUBSCRIBER.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4040.—Seedling Ferns.—R. G. W. R. appears to have sown some spores of a Maiden hair Fern, and he has got a crop of Pteris acrostichoides, and he asks for an explanation. Well, I suppose the spores of the Ferns have settled upon the Adiantum, and they were sown at the same time, or the spores of the Pteris floated in the air found the soil suitable for them, and consequently they grew. Such things often occur; in fact, I used to be

served in the same manner before I took extra precautions.—J. J.

4041.—A fly attacking Cattleya-roots (J. T.).—The roots sent appear to have been inhabited by a fly; but I suppose before you poked them to me you let the fly hatch, and you then set the empty houses away. Now, in all cases like the above, you should collect them as soon as they begin to appear, and very carefully burn them. I have great faith in oration, as I advise it in particular for this pest; but they require to be collected when young, because then they cannot have done so much injury to the plants, and the eye-stroke is the quicker got rid of.—M. B.

4042.—Soutioaria Steell (Justin).—This is the name of the flower you send, which, from its long, round leaves, obtains the name of the Shoe-lace plant. I have no doubt that it looks very nice, some ten or twelve flowers similar to the one you send all being situated upon short stalks thrown them together, and they make a fine display. I do not think I have ever said anything about the management of this plant. It is one of those odd out-of-the-way plants that I had really forgotten it; but better late than never, and I will be long. I am full of promises, however, at present.—M. B.

4043.—Linaria tristis.—J. Willis sends this for a name, saying he received it from his brother from the Canary Islands. It is a very beautiful species of the Toad-flax, and you should ask your brother to send you some ripe seeds and at once set about establishing it in your neighbourhood. It grows naturally in rocky places, and therefore it would succeed in the rocky, with but little soil about its roots. I should drop a seed or two into safe places in any old wall road about you, anywhere to get it established, for its glaucous leaves and its somewhat large flowers, which are greenish-yellow and purple upper lip, would make it a very welcome object in any position, and it flowers very freely.—J. J.

4044.—Collinsia verna.—S. Martin sends plants of this beautiful and charming annual, which I have found to flower best when sown in the autumn, pricked off into pots, and kept in a cold frame through the winter, when I have had it in flower in a superb manner from the beginning of April until the end of May. The flowers are so charming; the outer corolla is pure, the upper part being pure white, the lower part bright azure-blue, reminding one of the lovely blue Gentiana verna. Although an annual, it is a plant which everyone should grow, but it is a plant to which the slugs and snails appear to have an especial liking. I had also that it grows best when shaded a little from the sun, and not, like the majority of annuals, fully exposed to the sun's rays.—J. J.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W. C.

Names of plants.—B.—Apparently Allium pulchellum.—L. A. Crowley.—Taurus communis.—J. Wilson.—1, Odontoglossum maculatum; 2, Odontoglossum cordatum; 3, Oeodidium sepium (good variety); 4, Oncidium Gardneri.—J. Bryce.—Purple flower, biella speckled; the other some of the same, but the specimens are too small and withered to name accurately.—T. Mann.—Your Delphinium appears to be D. vitifolium.—G. Cunningham.—Canot name from leaves only with any certainty, but these are what I take your specimens to be: 1, Myrica bulbosa; 2, Rubus australis; 3, Coprosma Baueriana.—A. Hopps.—1, Spiraea palmata; 2, your White Rose appears to be R. sericea.—J. B. G.—Horseo stems.—T. J., Stratton.—Yes, we think Rose is Catherine Mermet.—H. Nichol.—Ben-bane (Hyoscyamus niger).—Mrs. Vaughan Hughes.—Yes, Fritillaria kamschatkica; other flower must be sent in fresher condition to name.—Mrs. T. P., Rugby.—Impossible to identify from such a bad specimen, and you do not give your name.—J. S. Smith.—Impossible to name from such specimens, and also the numbers have all become detached through bad packing.

Names of fruit.—S. S. B.—We cannot name Strawberries, especially when crushed to pieces, as in this case.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

M. S.—Fumigate frequently and lightly with Tobacco.

BIRDS.

4045.—Trapping and killing pigeons.—Will you inform me if it be a legal right to trap and kill pigeons? They are owned by a neighbour, who takes no notice of complaints; but as the birds are most destructive to my garden produce, I do not know of any other alternative.—CONSTANT READER.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 5d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 5d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, 40s. 12s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 5d.

"Hardy Flowers"—Giving descriptions of upwards of thirteen hundred of the most ornamental species of plants for their arrangement, culture, &c. Fifth and Sixth Editions. Price, 1s.; post free, 1s. 3d.

London: 37, Southampton-street, Strand, W. C.

GARDEN AND PLANT PHOTOGRAPHS

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded.

The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; out flowers, prettily arranged; pretty cottage gardens; our best fruits on the branch or branches, not in dishes; standard vegetables; good flower-gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS.—A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS.—First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or bush-fruits, to be shown on the branches, not in dishes. No prize will be awarded for photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES.—A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not wish to exclude real novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in July, 1893.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photograph may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and some note the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Covent-garden, London, W. C., and marked "Photographic Competition." All competitors wishing their photographs returned, if not successful, must enclose postage stamps of sufficient value for that purpose.

FLOWERS IN SMOKY SUBURBS.

THE dweller in crowded cities and smoky suburbs is sometimes filled with the desire to bring a little of the country into his humble plot. He envies the cottager, for there often the flowers cover the soil, and they seem to need no hand to constantly minister to their wants, the soil, air, and full sunshine giving them vigorous life. A different picture is presented in the town garden. Obstacles are often met at every turn, and perseverance is needed to bring to the fullest beauty the flowers that find a place in the crowded suburb. The Londoner or whoever he may be need not despair. The town garden may bring forth beautiful pictures when the proper plants are selected. More failures result from a bad start than from any other cause. Begin well and you will succeed, but lay down a false foundation and the whole business is vexatious. Before alluding to the best plants to grow in cities or their environs it will be profitable to devote a short space to the garden itself—soil, situation, and kindred matters. Usually the garden is composed of very indifferent soil, a mixture of builder's rubbish, odd bits of refuse, a singular hotch-potch medley of various materials, not exactly the type of "stuff" from which one can expect beautiful flowers to spring. Commence boldly by putting a little new soil, manure and lime—town gardens are usually deficient in this valuable substance—into the soil to make it worthy of the plants. If it has not been turned over for many years, as is sometimes the case where the house is not new, give the ground a thorough trenching, digging it up well so as to expose it as much as possible to the kindly influence of the rains and atmosphere, or frosts if the season of the year at which the work is done is in winter. Autumn and winter are the two periods of the year when this work is best accomplished, flowers then having departed for a time, and the ground is practically idle. My remarks are, however, made now, as everyone is thinking, of flowers and gardens in the summer months. Beware of false imitations of rocks, paltry attempts to reproduce mountain scenery. A great disfigurement to many otherwise pleasing town gardens is this so-called rockery, a heap of stones or hurrs thrown together anyhow, and providing very small habitation for the plants unfortunate enough to have a place there. The "pockets" of soil are too small to permit of vigorous growth, and the plants strive to look respectable under the starved conditions. Sometimes the Creeping Jenny will hide much of the ugly brickwork, but more often than not there is insufficient soil to promote free growth. Get the ground firstly in good order; then proceed to lay it out, taking care not to chop it up into a multitude of paths, but give every available space to flowers. As the object is to have flowers, in place of brick or stone edgings, form the edging of the London Pride or the Thrift, which grows well near large towns. I will now give a list of the plants that may be expected to live well in town gardens, and if the list is not very long it will contain many beautiful things. The Iris, popularly

called the Flag, is a splendid town flower, appearing even almost to relish smoke and a vitiated atmosphere. In the garden of the writer it makes a brave show each year, although this little space is not far removed from a busy city, and more than one kind may be grown, as the family of Flags is a very large one. Chief and foremost is the common garden Flag, or German Iris (*I. germanica*), which is recognised by its strong, sword-like, glaucous-coloured leafage, and brave purple flowers, bold, effective, and full of graceful curves, intense in colour, and though lasting but a brief time individually, appear in gay succession, one bud expanding after the other on the same sturdy stem. Even against dusty highways this beautiful flower will appear to be regardless of the unpleasant surroundings. Besides the common kind one may choose also the lovely variety *Coleste*, pallida, the milky-white Florentine Iris, Quon of May, also the Dalmatian Iris, and Madame Cherean, white, with violet colouring at the margin of the florets. The Iris fancier may also grow the tall, Grass-like Siberian Iris, but it is better to rely entirely upon the germanica types than risk failure with the other species and varieties. The Iris requires a good, well-drained soil, rather heavy than light, and once the plants are established they should not be disturbed at the root if broad-spreading masses are desired. Like many another perennial this brave flower hates disturbance at the root. It is constant interference with it that brings about failure.

THE CARNATION is a splendid town flower. It is used in the London parks with the greatest success, the Old Crimson and White Clove, sometimes called *Oleire* de Nancy, making good progress even in the centre almost of the metropolis. In my garden in Clapham—not a country village—I can grow a superb selection of all the leading kinds, florist's and the ordinary garden Carnations. The Chrysanthemum is one of the finest of town plants, apparently relishing the unpleasant conditions of town life. The unjoined list is of necessity small. Comparatively few hardy plants will live in towns, but from experience the following, if not so plentiful as in the country, always give a good return in the way of flowers for labour expended. Taking them alphabetically, we have the Japanese Anemones. *A. japonica*, a rose-coloured species; but the kind most largely grown is the variety *album*, or *Honorine Jobert*, in which the flowers are of the purest white, and invaluable to cut from for the house. A clump of this in the garden makes a fine picture, and the plant commences to bloom when the flush of summer things has passed. Provide them with a rich soil, well manured, and during the summer months give an abundance of water, as in town gardens in particular the soil quickly gets dry—almost dust-dry. Put in at the start good plants, not weakly scraps that need a lifetime almost to grow into respectable specimens; and once in position leave them alone, except for an occasional mulching, for several years. Constant disturbances at the root, as in the case of the Iris, is most hurtful. More plants are killed by mistaken kindness than by any other source. Then we may name in our small selection the Rock Cress (*Arabis alba*), smothered with white flowers

throughout the summer season, making little snow-like drifts and running riot hither and thither, deigning even to cover ground the reverse of agreeable to hardy plants in general. The White Rock Cress is one of the most accommodating of perennial flowers, and may be permitted to cover rockeries or tree-stumps with a surface of blossom. The Michaelmas Daisies will possibly occur to mind as an exceptionally attractive family, free in growth, and blooming freely at a season of the year when flowers are fast flying away. One wants, of course, to see the Aster in a country garden, filling the scenery with colour, brave masses of bloom creating a shimmering of varied purple and lilac tones in the landscape. This great North American family is composed of many "weeds;" but there are many gems, such as the dwarf *A. scris*, often a mass of bloom, the plant not growing more than 2½ feet in height. Then we have *A. besseriensis*, or *A. amellus*, as it is usually called, the flower being a mere variation from the latter; the species and a few plants of this are very showy in late September. One may also name *A. dumosus*, *A. linearifolius*, *A. ericoides*, *A. levis*, and *A. Novae Angliae*, the last-mentioned being the tallest of all, reaching a height of nearly 5 feet. The town gardener need not be deprived of the Bellflowers or Campanulas. A splendid kind for smoky atmospheres is *C. Rapunculina*, very free blooming, the flowers large and rich purple blue, and the plant is of easy growth. The writer has had for several years in his suburban garden a mass of this native Bellflower, whilst *C. glomerata dahurica* possesses much charm, the plant growing in ordinary soil, but requiring a moderately open position. Its clusters of flowers—hence its common name, Clustered Bellflower—are of intense violet-purple, and useful for cutting. The Giant Cornflower, for such it may be called, *Centaurea montana*, and its varieties are very free border plants, making rich tufts of growth, the flowers like those of an ordinary Cornflower, but three times as large, and varying in colour from pure white to quite a rose-shade. The remarkably fresh-looking *Erigeron*, or *Stenactis speciosus*, is a valuable border plant, growing well in ordinary garden soil, and bearing its large lilac flowers in profusion throughout the greater part of the summer. It is showy and free. The yellow-flowered *Coreopsis lanceolata*, which seems to live best in light warm soils, and the perennial Larkspur or Delphiniums are a host in themselves. Every old-fashioned cottage garden worthy of the name is enriched by broad, vigorous clumps of the Larkspur, the tall, straight, sturdy stems rising up from the luxuriant hush of rich-green leafage. During the past few years Messrs. Kelway and Son, of Langport, Somerset, have greatly improved this race by hybridisation, and in some of the newer varieties we get bold contrasts of colour and great beauty in the individual bloom. It is strange that some of the best of plants for town gardens are seldom seen there. The

PLANTAIN LILIES or Funkias are a case in point. Even deprived of flowers they are attractive to look at, the leaves broad, glaucous green in colour, not to be overlooked, and remarkably ornamental. *F. ovata* is one of the most suitable, as it seems

to stand better than the others the trials and hardships of a smoke and sulphur-laden air. Then we have F. Sieboldi, F. japonica, F. lanceifolia, and F. grandiflora, which has pure white fragrant flowers, requiring a sunny spot, and warm, thoroughly well-drained soil. The writer has seen even in the heart of London, where the householder is unblest with a garden, thriving masses of F. ovata grown in tube to adorn the flag-paved fore court. The chief requisites under these conditions is a good supply of water in the summer months, when the sun beats fiercely upon the pavement, and renders plant life unhappy. The great family of Perennial Sunflowers, or Helianthus as they are botanically called, form a beautiful group of hardy plants, preserving a distinctive family likeness, but differing in habit. The commonest is the double-flowered Helianthus multiflorus; then we get H. argyria and H. decapetalus, that grow to a considerable height, the shoots slender, and awaying their many flowers in the wind. All grow very readily in ordinary soils. Then the Day Lilies may be mentioned, and they will grow almost anywhere. All the plants named have the happy disposition of not being very particular as to the soil or their surroundings. They will live in the moist meadowy spots, asking simply to be left alone. Lilies are not good town flowers. One may sometimes see them in brave attire, but it is better to leave them alone, except, perhaps, L. croceum (the Common Orange Lily), L. umbellatum, and L. auratum, but when money is no object, a view of Lilies may be gained each year with new bulbs. The Creeping Jenny, full of charm when permitted to run over rockwork, Evening Primrose, the Mossy Saxifrage, London Pride, Golden Rod, Spanish Squill (Soilla capanulata), and Sedum spectabile may all receive admittance into our select list of town flowers. The Sedum succeeds in the smallest and poorest garden, the rosy flowers crowded on flattened heads, making a bright show in the month of September. The Japan Knotweed (Polygonum cuspidatum), if weedy in growth, living almost anywhere, on the top of an ash-heap or on a gravel path, is a very beautiful weed, but requires careful treatment somewhat to bring out the full beauty of its finely-arched stems and pondant strings of creamy flowers. I have often seen it bloom with great freedom in large towns, and if the display of flowers is not very imposing, the habit and leafage of this Japanese plant are attractive. The young shoots as they come up through the ground are said to be eaten by the Japanese, in the same way as Asparagus is eaten in England. Town gardens are usually much in the shade, through their small size and surrounding buildings, but even if the whole garden were deprived of the blessed influence of the sun, it would be possible to get some enjoyment out of it. Hardy Ferns delight in shade and moisture. Beautiful varieties of the Male and Lady Fern can be grown into large specimens, and such things as the Spanish Squill bloom each year with unflinching regularity. To ensure success, as before pointed out, begin well, incorporating, in the case of the Ferns, a fair share of peat with the soil, and remember that moisture is life to them. Many things suffer from the poverty of the soil. The London Pride reveals a different complexion when grown as if worthy of something better than ashes and brick-ende, and this remark applies to town and, in fact, all plants in general. Let gardening be thoroughly well done, a suitable selection of things made, and hours of recreation from business will be well repaid by healthy exercise, bringing into life gay flowers, a pleasure to see, sweet reminders of country gardens and waysides.

Pink Napoleon III.—When calling last season at Messrs. Kelway's nursery at Langport, I was much impressed with the value of the mule Pink for borders and beds as I looked on some large masses growing in the most exposed situations. At the time of my visit they were in full bloom, one mass of Napoleon III. being some 5 feet or 6 feet across. Some years ago, when living in North Hants, I grew these Pinks largely, and they used to hicom so profusely that it was difficult to obtain cuttings. I overcame this by taking the cuttings from some plants early in spring, allowing them to grow into growth, and then taking another batch of cuttings.—H.

GARDEN WORK.

Conservatory.

The weather at the time of writing is intensely hot, and shade and water will make up the principal items of management. Any plants which can be taken from the stove will do very well in the conservatory now. Palms, Ferns, and other foliage plants will give a cool appearance that will be usually much appreciated. Foliage planted out will be chemically effective hanging about; climbers of various kinds will also take off the stiffness. It is such an easy matter now to clothe bare walls that are naked; surfaces should be hidden with foliage and blossoms. I have before alluded to the value of fly-leaved "Geraniums" for this purpose, and they are also well adapted for filling wire-baskets to suspend wherever there is room. Achimenes also should be used for filling baskets. They are very effective when the baskets are of considerable size. Hard-wooded plants may now go outside for the most part, but they must not be taken from a shaded greenhouse or conservatory during this bright weather direct to the open air and placed where the sunbines can reach them or the leaves will suffer. If taken out during a dull time no harm will be done, but to place a plant outside in this scorching weather would turn the leaves brown in a few hours. If they are taken out whilst the sun is rather late, place them under the shade of a tree till the foliage has hardened a bit, or else place them on the north side of a building. They can be moved to a more open place when the foliage has got hardened a bit. Camellias must not be placed in the sun at all, as the leaves may scorch, and a Camellia with burnt leaves is disfigured for a long time. Ventilators should be left on all night now. The night air when there is no wind is very beneficial to all greenhouse plants. Watering should be as far as possible be done in the evening. There will of course be plants that will require water more than once a day in such drying weather, and an eye must be kept upon them and water given when required. Young stuff will now be in pits and frames, and can easily be made comfortable with shade and a gentle dewing over when closed in the afternoon. As the plants get larger and stronger, air will be left on all night, but at present young stuff will be kept pretty close to encourage growth. Use the engine or syringe as freely as circumstances will permit.

Stove.

There is much beauty of leafage in a collection of Crotons. I do not know that I should care to have a bonus lot of Crotons, but they are charming among Ferns, chiefly placed and clearing the air, and an eye must be kept upon them and water given when required. Young stuff will now be in pits and frames, and can easily be made comfortable with shade and a gentle dewing over when closed in the afternoon. As the plants get larger and stronger, air will be left on all night, but at present young stuff will be kept pretty close to encourage growth. Use the engine or syringe as freely as circumstances will permit.

Fern-house.

This is a good season for visiting a Fern nursery and selecting a few fresh varieties. One might easily make out a list which might be recommended; but it will be better and more satisfactory for the buyer to visit one of the large growers and see what he has in stock. If we could have all our desires gratified, I should say build me a nice roomy house, and let me have a representative collection of Adiantums. Scarcely anything could be more interesting than a house filled with Maiden-hairs of every kind, from the tall-growing trapeziform to the small, but elegant, acumin. Probably an enthusiast in Ferns would want to carry the matter further. A household of Gold and Silver Ferns well grown will be equally interesting to the Maiden-hairs, and then we must have a cool, dark corner somewhere—underground it might be—for the Fifty Ferns. Mosses, again, can be had in almost endless variety, and to the student of Nature they would be as interesting as the plants with larger and more brilliant leafage. Moisture must be freely present now in the Fern house. Much of the humidity may be obtained by damping floors and walls. Do not use more shade than is required for plants which are intended to supply foliage for outdoors.

The Rose-house.

Tea Roses are beautiful outside in the open, and most of us must have them there or not at all. But I have heard many a struggling Rose-grower wish for a glass-roof to shelter those which are not so very happy outside. It is positively true that it may not be wise to perpetuate the constitutionally weak; but if this were carried out to its logical conclusion what would become of the Marching Nile? And where is there a Rose of its colour to take its place? Then, again, see how easily the town gardener might have his roses if he had a glass-house. Whether heated artificially, glass for Tea Roses in the suburbs of towns and in cold districts generally is very desirable, and it

will be more largely used for the purpose in the near future. Let the house be light and the coolers well made and one cannot then go far wrong.

Window Gardening.

The other day I noticed a window in a cottage residence very tastefully decorated with blue and white Campanulas. At the bottom of the window were two red and one yellow Tuberosa Begonias and four of these Campanulas; two of white and two of blue were suspended, two in baskets and the others resting on small brackets fixed inside the window frame. When the Campanulas of other plants would take their places.

Outdoor Garden.

Alpine plants on the rockery will need both water and mulch. Cocoa-nut fibre will do for mulching purposes. It will also will need moisture and should have it applied liberally. If we are at the beginning of a cycle of dry seasons it will pay to make a better provision for a supply of water and its distribution. Nothing can be worse than the water supply in many gardens, and the only method of distribution is the cumbersome and old-fashioned one of dragging it about in pots and tubs. If there had been a good supply of water hoses would have been in a better condition than they are. There are plenty of good blooms of course when well cared-for on good land, but Roses and other things are suffering the drought more than they ought to be. It is better provision had been made. Mulching may be done any time when the bark will work. A coating of water to both Briere and the plants from which buds are required will generally bring them into condition. With the exception of "Geraniums," bedding plants are not making much show yet. Dry seasons just suit the Pelargonium family. Keep the soil loose among the plants by frequent stirring, and nothing more is required; but Calceolarias, Verbena, Heliotropes, Asters, Siccas, and Vinca, will need both water and mulch. Sow Myosotis distillifolia in the shade for Blooming next spring. Silene compacta, Lunanthes Douglasii, and other hardy annuals may shortly be sown for flowering next spring. Transplant Canterbury Bells and other biennials or perennials sown this spring when large enough, but the seeds of most things have grown badly in consequence of the drought. Sow Brompton and East Lothian Stocks. Wallflowers may still bloom.

Fruit Garden.

It is time the stock of Strawberries for forcing was secured, and if layered in small pots those layered first will soon be ready for pining in the fruiting pots. I shall never again grow Strawberries in pots for forcing in a smaller size than 6 inches in diameter. The labour of watering is too great and for late fruit 7-inch pots will be better. I need hardly say anything about varieties further than that those who can grow British Queen cannot do better than stick to it. Vicomtesse de Thury for early work, followed by Sir J. Paxton, J. Veitch, and President. There is no fear about these things, if they have merit, being neglected. The danger lies in getting rid of an old well-tried variety and taking up something not so good and reliable. Where kept a seedling does well it will hold its own as a forcer; the fruit must be thinned to get size, but it offers advantage for the forcer as ripening its crop altogether, the fruit can be gathered, the plants cleared out, and the space occupied with others. Outdoor Strawberries have in many gardens done badly for want of time. It is a mistake to keep plants too long in the soil, and in the preparation of ground for new plantations may well be found very beneficial where the land is light. Sift the soil on the day on which the ground has been trenched, and lightly fork it in. Rubens' Blooming fruit generally are very small. If it could have been managed it would have been well to have mulched all these things. The autumn-bearing Raspberries are coming up well, and in most cases they will need more support. Break up old Mushroom-beds, or get a few loads of sheep-droppings in manure and spread among the Autumn Raspberries, or any fruit-trees or bushes. Fruit-houses must have free ventilation now, and borders must be attended to.

Vegetable Garden.

Mushroom-beds will require careful attention especially in the matter of watering. Beds in houses, unless the position is a very cool one, will produce maggoty Mushrooms and those which can only be used in the button state, and the difficulty with beds in the open air is to provide a damp atmosphere. An underground collar is the place for Mushrooms in summer. In winter the beds are supplied liberally with water to prevent the soil from becoming too dry. If the weather continues to be so dry, the surface of the ground should be trenched, and lightly fork it in. Rubens' Blooming fruit generally are very small. If it could have been managed it would have been well to have mulched all these things. The autumn-bearing Raspberries are coming up well, and in most cases they will need more support. Break up old Mushroom-beds, or get a few loads of sheep-droppings in manure and spread among the Autumn Raspberries, or any fruit-trees or bushes. Fruit-houses must have free ventilation now, and borders must be attended to.

Work in the Town Garden.

Gardening in towns is in some respects not without disadvantages. In such weather as we have had of late a flowering that may not appreciate to have a regular and unobstructed supply of water at hand. In some districts of London the water companies have interdicted the use

In cold or northern districts the operations referred to under "Garden Work" may be done with less delay to a fortnight later than is here indicated, with equally good results.

of water for garden purposes; but, all the same, I fancy that very few men who really care for their floral pets would be above appropriating a few cans daily in order to keep them alive. In many country places water is now so scarce that it has to be fetched for miles, and in some cases is only available in the smallest quantities. In one instance that has recently come under my notice the gardener has been obliged to let most of his greenhouse plants die, very little more water than enough to supply the household being obtainable, and in several others the bedding-out has not been done yet, simply because there is nothing to water them in with. The pall of smoke, too, that always hangs more or less over a city or large town tempers the burning rays of the sun to an appreciable extent, and plants both under glass and outside consequently suffer somewhat less from intense heat. The atmosphere in large towns is very much purer now than at any other season of the year, owing to the comparatively small number of fires kept going, and consequently glasshouses of all kinds may be very much more freely ventilated. The best time to give air is quietly now is during the night and early morning, when even in the very heart of London the atmosphere is often remarkably clear and pure; but during the heat of the day it is advisable to close the roof-ventilators, or, early so, in order to check evaporation as far as possible, giving air only at the sides or in front of the house. Watering, that is to say the principal supply, is best given in the evening at this season, when the plants are drinking in moisture and strength all night, and by the morning will be able to utilize the orinal of another day. The stock should, however, be looked over in the morning as well, and in some cases about noon also, and any that are dry and re-plenished, while the early morning damping down ought not to be omitted. Tomatoes must be abundantly ventilated both by day and night, and be liberally supplied with water also. A good syringing once or twice daily will be found beneficial under present circumstances also, especially in houses that are fully exposed to the sun. Pot off Chinese Primulas as soon as possible and make a first sowing of Herbaceous Calceolarias.

E. O. R.

autumn-flowering plants has been in the bloom-pots for some time, but the late sorts will not do reported yet. In potting a couple of inches, in some cases more, of space is left at the top for top-dressings when required. Our loam is not good enough to produce extraordinary results, but a little fortifying with artificial will help. Years ago I have used night-soil to improve poor sandy loam with very good effect, but this is not convenient now. The plants, when the potting is completed, will all stand in long lines on edge of shelves, and stakes and wires run alongside to secure the plants to, as the wind is sometimes troublesome here. Shifted winter-blooming stuff, such as Primulas, Cyclamens, Cinerarias, Begonias, &c. into 5 inch pots. Cut down Pelargoniums and put in the cuttings. Commenced huddling the standard Briers; have had to water them to get the sap in motion—either had to do this or wait for rain—and young standard Roses will be scarce next year; in fact, good stuff nearly always is scarce and dear. Planted out a lot of Fuchsias; they will make a show in the borders, and I shall get some soft cuttings from them.

ROSES.

YELLOW BANKSIAN ROSE.

ALTHOUGH the White Rose that Robert Brown named in honour of Lady Banks was introduced twenty years earlier, it was not until 1827 that the Yellow Banksian Rose was brought to England from China. It quickly became an established favourite, and still occupies a prominent position in general esteem, for it makes a charming climber, able under favourite circumstances to cover the side of a house and to provide a profusion of its clusters of miniature yellow flowers. It is, unfortunately, not abso-

but what it would succeed fairly well with the growth pegged down. But it does still better under what is known to gardeners as the cutting-down plan, which means that all the growth is cut down in the winter to within about 4 inches of the ground. Under this system it does not flower so early, but the blooms come larger, and are more continuously produced—in fact, the plants continue to flower right up to the time that frost cuts them down. Unpruned plants will, however, produce much the largest number of flowers, especially if the roots receive the assistance of an annual dressing of manure.—J. C. C.

3998.—**Marechal Niel Rose.**—This Rose blooms on wood made the preceding year, and it is therefore necessary to cut back hard after flowering, so as to induce a strong, free growth. Leave from two to three eyes of last year's wood, and encourage these to break by wall syringing them daily. Little or no water will be needed till growth is being freely made, and then abundant supplies must be given. At the close of the autumn prune back the shoots to about two-thirds of their length. This is the only way to get an abundance of high-class blooms. Pruned in the ordinary way there will be very few flowers.—J. C. B.

A new Rose.—A good new Rose called Carmine Pillar, a curious and not very happy name, is likely to prove useful for pillars and

A flowering shoot of the Yellow Banksian Rose.

THE COMING WEEK'S WORK.

Extracts from a garden diary from July 1st to July 8th.

Finished patting in cuttings of Pinks and commenced layering Carnations. Went over Plums and Cherries on walls to remove breakwood and nail in young shoots to fill up vacant spaces. Gave Peaches and Apricots on south walls a good watering; they have also been mulched and the garden engine has been used two or three times a week. I have laid an embargo on all the soap-suds made in made laundry on washing-dishes, which are used wherever and cessary for cleaning fruit-trees, Roses, &c. A little air is let on all the houses now at night, except those devoted to Cucumbers. I have been working two houses side by side to test the merits of ventilation or the reverse. One house has been kept close, no air at all given, but the south side is shaded; the other is ventilated moderately every warm day, and is also shaded on the south side. The plants are very healthy, but the fruit takes twice as long to come to the cutting size as in the house where no ventilation is given. This is, I suppose, what most people would expect, and where the produce is sold nearly double the amount will be made from the house which is not ventilated, although both are the same size. Of course, the fruit from the unventilated house will not keep so long after being cut. Cucumbers rushed on in this way soon get fishy; but as a means of turning the honest penny the man who runs his place on the old-fashioned plan would starve. Wrote over Melons to give water and remove laterals. Good Melons are plentiful now, the melons having given them better flavour than customary. Melons want doing just to the right turn and casing them, as the flavour in the best form soon goes. Planted another house with Melons to follow in succession. Made a last sowing of Peas, the variety being William I.; shall not sow any more with the view of gathering Peas from them, but shall probably make a sowing or two to cut green when about 3 inches or 4 inches high to flavour soups, &c.; they do very well for this purpose when Peas are scarce. There has been a bad season for Peas, the weather too cool for even when mulched they were killed on their feet, & good; if not used the very day they became fit they will be old the next. Still shifting on Chrysanthemums. The

lately hardy, but if it be planted on its own roots, even if there should come a winter so unusually severe as to kill the tree down to the ground line, it will then be almost certain to break again from below. In a climate like that of the Isle of Wight, however, the Yellow Banksian luxuriates, and when the young growths have not been injured by late spring frosts, the display of bloom observable on some of the houses there is magnificent. With flowers resembling nothing so much as yellow double Cherry blossom, and with shining deep-green leaves of three or five leaflets, there is no more distinct and characteristic Rose, nor is there any whose flowers collectively make so telling an effect, while individually so dainty and so delicate. The Yellow Banksian is a sun-loving plant, and may be better cultivated in an abnormally hot and dry situation than in one at all habitually shady or damp, and it also makes a fine subject where it can have plenty of room in a Rose-house, some growers making it a favourite stock on which to work Marechal Niel under glass. It need to be sometimes said that to get the Yellow Banksian to blossom freely it was necessary to cut out all the strong growths, leaving only the twiggy shoots to flower; but this is not the case, except where the wood is not fully ripened, owing to a lack of exposure to the sunshine. If this Rose be grown in a suitable situation, it is of the greatest beauty. B.

Monthly Ross.—This old Rose is such an accommodating plant that I do not doubt

other such positions. The flowers are single, quite as large as those of Rosa rugosa, and the colour is deep-crimson—a glorious hue, very distinct and pleasing. It is free, bright, and essentially a thoroughly good garden Rose, and likely for its freedom and bright colour to be much grown in the future.—V. C.

A note on Tea-scented Roses.—This beautiful class wins the heart of every lover of flowers. It is full of beauty, the flowers of refined and delicate shades, yet there are not wanting those of decided colours, even crimson, as in Souvenir Thérèse Levet. This section may be split into two, keeping the more vigorous growers to themselves, and the popular Gloire de Dijon, that mounts up the cottage chimney and flings its deliciously-scented flowers in the rustic window, is representative of this type. The Tea-scented Rose is just growing in public favour. Its lovely flowers are irresistible, and only a supposed want of hardiness in the plant makes those who would grow this class largely hold aloof. Each year rosarians add to their treasures, and those societies offer a greater number of prizes for the Tea flowers. About four years ago the National Rose Society inaugurated a special exhibition for them, and its popularity justifies the undertaking. In old books and catalogues one often finds such a remark as this: "Owing to their tenderness Tea Roses cannot be properly grown in the open air, as they need protection. Under glass their flowers become well developed." Everything is changed now, and even in cold localities the plants prove successful. Give them a well-

drained loamy soil, warm, not too heavy, or much exposed to cold winds. The writer has seen them thrive on a breezy hill-top, and stand many degrees of frost without injury. If the shoots get cut down, new growth takes place in the spring, these carrying a wealth of flowers, though a little later in the year. When strong, Tea Roses will bloom from June until stopped by frosts. In very mild winters a handful of flowers may often be cut for the house on Christmas Day, but it is not often on such a day that a sweet bouquet can be provided. A little pro-

The Sweet-scented Tobacco (*Nicotiana glauca*).

tection, however, in severe weather is advisable, and this may be given by Fir-branches, or dry fronds of the Bracken. If the crowns are safe no fear need be felt as to the display of flowers. The stronger varieties, as Gloire de Dijon, are adapted for climbing over arches, pillars, or trellis-work. In spite of many new climbers, this fine flower holds its own for freedom, vigour, and sweetness. It is a pleasure to see that in smaller gardens the Tea-scented Roses are being grown freely and well. They are far better than ugly standards or indifferent Hybrid Perpetuals.—V. C.

THE SWEET-SCENTED TOBACCO (NICOTIANA AFFINIS).

The plant of which we here give an illustration is one of the best things of its kind that can be grown in a garden. It is a most excellent bedding plant, and does very well in pots or planted out in a cool greenhouse. This Tobacco-plant, although well known, is not grown half so extensively as its great merits deserve. B.

Tufted Pansy "White Swan."—It is probable that this capital Tufted Pansy is sometimes taken for Countess of Hopotoun. I think it may have been so at Claremont, where I saw it growing in huge clumps on the borders last week. No white variety could possibly have bloomed more profusely, and although Snowflake may be a trifle whiter, it could hardly be more effective. White Swan is one of the varieties raised at Bedford some ten years since, but I had lost sight of it for some time, and was pleased to see it doing so nicely at Claremont last season.—D.

Dianthus plumarius.—What delightful gems these single rock Pinks are! On the rocks good clumps of varied colours are neat, graceful, and effective. They are also attractive in the borders, and most useful for supplying cut blooms for the decoration of vases. Considering their many merits and the ease with which they can be grown (a shilling packet of seed gave us the start), for they grow freely from seed, and can afterwards be increased by piping, if required, it is surprising they are not more often seen in the case.—R.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS IN THE OPEN BORDER.

WITHOUT special attention to watering and mulching the plants, I fear Chrysanthemums in the open border stand but a poor chance of success this year. Naturally, this flower is a moisture-loving one; where water is scarce, or the time to apply it is limited, the plants suffer, and when allowed to become dry at the roots for any lengthened time, that free growth which is so desirable receives a check, the lower leaves shrivel, and eventually cannot perform their natural functions. Any house slop or liquid-mannure that can be spared should be utilised for watering the plants, afterwards providing a mulching of half-rotted horse-mannure, if obtainable, as a means of conserving the moisture about the roots by the prevention of evaporation from the soil. If manure of any kind cannot be had, decayed vegetable refuse, to which is added a portion of wood-ashes, road grit, or old potting-soil, adding a handful of quicklime to every bushel of soil as the mixing takes place for the destruction of slugs or any other vermin. Plants well soaked with water and directly afterwards mulched in this way will withstand a long period of drought with impunity, as compared to those that simply receive a watering and no mulching. It is surprising how quickly the moisture evaporates from the soil where no mulching is applied, owing to the fissures made in the surface soil, through which the sun absorbs the moisture. Even if no mulching material could be obtained at all, if the surface soil was broken up and kept loose, so that cracks would not form the plants would not suffer nearly so much as though nothing were done at all. During such excessively hot and dry weather that we are now experiencing, any little aid in the manner indicated will be felt by the plants as an advantage in encouraging growth. The plants will require some support while growing to prevent the shoots being broken or bent. A single stake in the centre of each, to which the branches can be loosely but securely looped, affords the readiest means of security without unduly crowding the shoots. All the light and air available is necessary to give the best results in a full flower crop later on. These border plants do not require any pinching or thinning of the shoots, but allow all to grow freely and uninterruptedly. Long spikes of bloom, with foliage attached, are then available, which are far superior to the short and slender spikes obtainable by continually pinching of the plants, even if there are fewer of them. E. M.

4038. — Manure for Chrysanthemums.—The manure from doves would answer quite as well as that from pigeons in a liquid state for these plants. As it is mixed with grit it might be laid on the top of the pots, $\frac{1}{2}$ inch thick, as a top-dressing. In this way it would be easier managed than making it into liquid. The corn mixed with it would not interfere with the plants at all. Perhaps some of it might grow. That is easily removed, however, when the plants are growing.—E. M.

— Yes, the manure referred to would do as well as that of pigeons. The corn will do no harm whatever.—B. C. R.

3987. — Plants for Sheffield.—I presume flowering plants are intended. If so you will find the following among hardy perennials, &c., to thrive more or less well, according to the locality, whether very smoky or otherwise: Auriculas (garden or alpine kinds more particularly), Armerias (Thrifts or Sea Pinks) in variety, Campanulas of sorts, Carnations, Centaurea rubra (Valerian), Delphiniums (Larkspurs), Doronicums in variety, Helianthus (Perennial Sunflowers) in variety, Hollyhocks, C. latifolium, and C. uliginosum, as well as the ordinary autumn-flowering varieties of C. indicum; Marvel of Peru, Veronicas, Tritomas (Torch Lilies), Creeping Jenny (Lysimachia vulgaris), and Lilies of several kinds, particularly L. candidum, L. auratum, &c.

tigrinum, L. Martagon, and L. speciosum. Of annuals Tropaeolums (Nasturtiums) in variety, Cornflowers, Mignonette, Annual Chrysanthemums, Sunflowers, Marigolds (African and French), as well as the common "pot" Marigolds (Calendula), Phlox Drummondii, Aster, and Ten-week Stocks. The Virginian Creeper, Vine, Fig, Clematis, Jasmine (white and yellow), Euonymus, Anacardium, Lilac, Weigela, Gum Cistus, and Rhododendrons will also succeed.—B. C. R.

— It depends upon the kind of plants that you wish to grow, but I presume ordinary border things. If you live amongst houses so to speak, avoid Roses, but if in the suburbs, away from dense smoke and dust, then you may grow the queenly flower, especially those kinds mentioned in GARDENING, June 10th. Advice upon plants for large towns has been given before in GARDENING, and further notes upon the same important subjects to those who live in towns will appear soon, probably; but I may mention that in your plot you can have good Carnations if the ground has been previously well prepared. This is more than half the battle, and you will do well to read my note in last week's issue upon a "small flower garden," and the plants there mentioned will succeed also in Sheffield, if the situation is not too smoky. Make a point of getting some good Chrysanthemum roots, especially if the variety Jules la Gravière, and the old Empress of China. They are very charming in the open, even in a smoky atmosphere. In a garden, not far from London, I visited recently, there was a splendid show of flowers in the borders, comprising many things not supposed to succeed under such conditions. Carnations, Pinks, Irises, which are very good town plants, Lychnis Hoegaans, Stonecrops, and Creeping Jenny, over the rockery; Erigeron speciosum, Tufted Pansies, Sweet Peas, and various annuals, beddore in variety. You cannot do great things this year. The time for plenty of hardy flowers has gone by—at any rate, to get effect this year—but if you wish to keep the garden this year put in hedges at once, Tuberoses, Bagonias, Dahlies, Calceolarias, &c. If the garden is at present bad and in quite a rough state, no good planting can be done until the autumn. Read advice given in the answer about "a small garden" as to its preparation.—C. T.

4030. — Francoa ramosa.—This is appropriately named Bridal Wreath, or Maiden's Wreath, the flowers being white, and produced freely in racemes. It is a thoroughly useful plant, and may be grown from seed, which should be sown under glass in the usual way, the soil to be light, and the pots well crooked. When of sufficient size pot off the seedlings, and keep them in a greenhouse. They do not need artificial heat, but the Francoa is often grown well in winter; even it may be planted outdoors in sheltered, dry, warm situations, such as in the south of England. The flowering season is lengthy, the plants producing a free display of the long racemes. It is a Chilean plant. If you have a greenhouse, or one of the little structures attached to dwelling-house, you may grow with success the Francoa.—C. T.

— Francoa ramosa may be raised from seeds or division. It is not quite hardy, but may be wintered in a cold frame or cool greenhouse. There is no difficulty in its culture if treated as a rare plant in winter. It does very well planted out in summer. If grown in pots use rich, free open soil. Under glass it flowers in spring, but the season varies a little, according to temperature. I have had it in bloom in March.—E. H.

Silene virginica (Fire Pink).—Without doubt this is one of the most brilliant flowering plants to be found among hardy perennials. Under cultivation, however, it is not of that robust constitution that one would desire, or such as would make it one of the most popular of choice perennials. A mixture of peat and loam, rough and fibrous, and freely mingled with old mortar rubbish, sandstone, or charcoal suits it fairly well, and planted on the higher parts of the rockery where its roots can come into contact with the stone blocks, it is, generally speaking, content for a time. But in whatever position or soil it may be found to succeed best, let it be encouraged to the full, for we have very few plants possessed of such brilliancy as this.

TREES AND SHRUBS.

SHRUBS FOR THE ROCK GARDEN.

DAPHNE BLAGAYANA.

In reply to "B. S." and others, this *Daphne* (figured below) is a most delightful little shrub for the rock garden if planted in a partially shaded position where it will not get dried up in hot weather. It was discovered by Count Blagay in 1837 in Carniola, where, according to M. H. Gussone, it is one of the most beautiful and rare plants, growing along with *Erica carnea*. It is said to be good for forcing. It has compact umbels of yellow and orange flowers, 1½ inches across. K.

Crowding up shrubs.—In both large and small gardens one sees many very beautiful shrubs destroyed by the senseless way of crowding them up together as if to destroy their characteristic growth. The beauty of a shrub of whatever kind is in its natural habit, its form, and outline. This is gone when the plant is crammed up in such a way that it is impossible for it to reveal its true character. Amateurs are greatly to blame for this careless style, and I hope that in the coming autumn when alterations are made in the garden that thought will be given to the proper growing of shrubs. I noticed a Mock Orange so crowded up that a very few branches got to the light. These were smothered with flowers, but one can imagine the beauty of the shrub when in the open, unfettered by neighbouring things and permitted to assume its natural habit, that of a graceful, distinct, and pretty shrub. One could name many other instances; and then in the autumn it is common to see a man chopping about the roots to make what is called a tidy garden. Even the little tender roots appear on the surface, chopped up with the spade, handled by one who knows nothing about shrubs, and does not care. The Guelder Roses, Lilacs, Philadelphiaeas, Mock Orange, or Syringas as they are popularly called, and many other shrubs that I could name are never allowed to flower properly in many gardens. Then again why persist in continually planting Conifers in towns, the shrubs that of all others detect an impure, dusty, and smoky atmosphere? Conifers, whether in town or in the sweeter air of the country should always be planted with the utmost caution. Nothing looks worse when out of health, and nothing is more difficult to get vigorous again. The little "Monkey Puzzles" in gardens are an eyesore than otherwise.—V. C.

4031.—A Privet hedge.—The first week in February is a good time to cut down the hedge; it might be cut in November, but you would lose the effect of its greenery through the winter. Any time before the sap rises is a suitable period to cut hedges of this kind, and the time named is as good as any. The hotter plan would be to put in cuttings by themselves when cutting the hedge down. Cut them in pieces 10 inches long, cutting square below a joint, insert them in rows 4 inches deep, with a little sand at their base if the land is heavy. Make the soil very firm about the cuttings to prevent the frost upheaving them, allow them to remain for a year, and then fill up any gaps in the hedge with the plants which would be certain to grow. If cuttings are inserted in the hedge at once they might not grow, and the gaps would still be there.—S. P.

The hedge must be in a very exposed position, or else the soil is too rich, and the growth consequently too soft and sappy to withstand much frost. Even when living in the midland counties I never remember Privet being winter killed, and have always regarded the plants as perfectly hardy. The best time to cut the hedge down would be in the spring, just as it is commencing to make fresh growth, but it is not too late yet. The gaps should be filled up with sturdy young plants in October, November, March, or April.—B. C. R.

Shorea galacifolia.—This lovely American plant belongs to the natural order Dipterocarpaceae, and is still rare in gardens. A plant in a somewhat dry, sunny position died last winter, while another in a moist and shady position, sheltered by stones, has not only survived, but has bloomed well on a rocky in Exeter. The flowers are bell-shaped, white, shaded with rose, on stems 4 inches to 6 inches high, forming an excellent contrast against the leaves, which are of a very distinct reddish-bronze, turning to crimson.—F.

ORCHIDS.

CATTLEYA SKINNERI AND ITS VARIETIES.

I AM asked by a "Lady Reader" to say something about this beautiful plant? She went to the Temple show, and saw the very fine plant that was exhibited there by Mr. Ballantine in the collection of Baron Schroeder, and really there is no wonder that any lady should have fallen in love with its beautiful soft, satiny-rose-coloured flowers. It is now close upon sixty years ago since the plant was first sent home from the warmer parts of Guatemala, and later on by some of my personal friends from Costa Rica, and various other places in Central America, and in Guatemala it is known by the country people as the Flor de San Sebastian, and is used to decorate the churches of the saint, which occurs at the season at which it usually flowers, and I think from the day of its first introduction it has never been lost, but it has been maintained with varying degrees of popularity ever since. I have grown it in varying numbers for more than forty years and in various sizes; at the commencement of my cultural acquaintance I had several specimens nearly as large as that etched by Mr. Ballantine before mentioned, and which used to flower most profusely. One, a very fine large-flowered variety, with short hurls, I came across some ten years since, so that it cannot be called a very refractory species; but many a time I have seen the plant on its last legs through having too much heat and moisture given it; and then, again, from being too severely dried in winter; but *C. Skinneri* does not like to be either kept overdry nor too wet or warm, but it likes to be kept in about the same temperature as *Laelia purpurata*, and to be kept sufficiently moist to prevent the hurls from shrivelling. This *Cattleya* does not differ much in its colour, although some slight difference may be found in its size, and in the shading of the beautiful soft satiny-rose of its flowers. Until the Messrs. Veitch & Son, of Chelsea, first introduced the pure white-flowered form we did not have a thorough distinguished variety, but this having exactly the same habit and pure white flowers, with a faint tinge of lemon in the lip, is one of the most charming white Orchids known. After a little while a

jected to; but I should say either that she herself, or that her gardener has been treating the plant to syringing with other stove plants, and so this has by constantly keeping the hurls surrounded with water, which has run down the sheaths and ultimately rotted them, caused the bad appearance which she complains of, but which "Mrs. D." must quietly consider as her own fault if brought about by the cause here given; but at any rate it has been caused by bad management, and she must tell me the treatment she has given it, if I have not guessed right already. I have always cautioned growers of *Cattleyas* against the use of the syringe, for I have a very acute feeling respecting some *Cattleyas* left under my charge for a month in my young and boyish days, and which I deluged with water from the syringe every morning and evening during that time, which resulted in just the same conditions mentioned by the lady above named. These were not *C. Gaskelliana*, however, for this variety was not known in those days, or if known the name had not been given to it, for it was not until about ten years ago that the plant was introduced by Mr. Sander, of St. Albans, and given this name, but which I think I had grown some years previously under the name of the summer-flowering *labiate* and *labiate pallida*, and I am very thankful to Mr. Sander for rescuing this Orchid from oblivion, and dedicating it to such an assiduous grower of these plants. Now *C. Gaskelliana* appears to vary very much in the colour of its flowers; indeed, like all of this group, the different types are extremely variable, and now when we have got such a lot of grand-coloured *Cattleyas* to choose from, of course, a had coloured *Gaskelliana* does not count for much, but in the earlier days we were thankful for small mercies. This plant, I have been told by Mr. Sander, is one of the famous Roxburghian collections from the Venezuelan range of South America, and it flowers upon the young growth before that is finished from about now until the month of August, some varieties being exceedingly beautiful, but all of them lighter in colour than the old type of *labiate*, of which Mr. Sander had such a magnificent lot home during the last year or two. I advise "Mrs. D." to give her plants a short rest by keeping them comparatively dry, exposing

Daphne Blagayana.

second variety cropped up in the form called *oculata*, which is somewhat larger in size, pure white, having a very deep-purple mark in the throat, and this keeps a very rare plant in collections—indeed, so also does the variety *alba*, although its very high price has gone. MATT. BRAMBLE.

CATTLEYA GASKELLIANA.

THE enquiries of "Mrs. Dunkley" are as to the growths of this form of the *C. labiate* group becoming weak and rotting? But she does not say what has been the treatment they have been

kept to, and after this set them growing again at once, which means you may get a growth out of them which will not flower this year, but which in all probability will be strong enough to produce a flowering growth another year if you scow the use of the syringe. MATT. BRAMBLE.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in

INDOOR PLANTS.

3991.—**Plumbago capensis.**—Your plant will bloom in due course if treated liberally. It is probably root-bound, and must either be well fed or be repotted. The fertilizer you mention is an excellent one, and if used according to the directions will do the plant a lot of good. The season not being far advanced I should shift into a pot 2 inches larger, using good loam with some of the fertilizer added to it. This Plumbago being of very robust habit requires a lot of water when growing and coming into bloom. If fairly treated it is one of the most satisfactory plants an amateur can grow, yielding an abundance of blooms for cutting.—J. C., *Byfleet*.

4034.—**Plumbago alba.**—Try instead *Clematis lobata*, *Indivisa*, *Niphetos lloes*, *Lapageria alba*. If there is a cool, shady corner, and *Jasminum gracillimum*.—E. H.

— I should recommend *Abutilon* *Boule de Neige* to replace the Plumbago; it is much used for floral decoration, the petals being carefully turned back and the centre (in my opinion foolishly) picked out.—A. G. BUTLER.

— You cannot do better than substitute a White Rose for the Plumbago. Climbing *Niphetos* is the Rose you want; but in a year or two it will probably require a larger pot than the one you are using now. The White *Abutilon* makes a good climber, but the flowers do not last long when out.—J. C. C.

— Yes, the great drawback of the flowers of the Plumbago is their short life. They are very poor to cut, quickly withering, and not regaining much of their former freshness. But you might get a good plant of the *Lapageria alba*, which I should think would meet with your requirements. The flowers are waxy white, produced freely on the tender shoots, and are quite wreaths of bloom in themselves. It grows moderately fast when in a border, thoroughly well drained, and the soil a mixture of good peat and turfy loam, a few nodules of charcoal, and a sprinkling of sharp silver sand. The plant requires a considerable amount of water in summer, and it is most important to have the soil thoroughly well drained, otherwise it gets sour, and the roots become diseased. I suppose that few plants are grown more largely for cutting than this White *Lapageria*.—C. T.

— *Rhynchospermum jasminoides* is a very free-flowering, pretty, and fragrant climber with white blossoms, and succeeds well in a large pot, while the flowers last fairly well in a cut state. *Passiflora "Cucurbitaceae Elliot"* is a lovely thing, with pure silvery-white flowers, but these are, of course, very fugitive, like all the rest of the tribe. *Mandevilla suaveolens* generally thrives well in a cool-house, but this must be planted out in a well-made border in order to succeed.—B. C. R.

— *Swainea alba* is a much superior subject to the White Plumbago; the flowers are much more freely produced, and last much longer when cut. Beyond these advantages it gives so many more flowers during the winter, when Plumbagos are generally at rest. Abundance of water is required, and plenty of pot-room, or the foliage is liable to attacks of red-spider, which checks not only the growth, but limits the flower supply. If the pot can be stood on a border, and the roots allowed to grow through the pot into the soil so much the better. When this plant is wholly growing in a border it is apt to make too much growth at the expense of flowers. Syringe the foliage every evening as a preventive of red-spider.—S. P.

4001.—**Zonal Pelargoniums.**—If sufficient heat can be provided any varieties can be bloomed in the winter; but if not none will do any good. Some of the best for winter blooming are *C. V. Raspaill*, *Seavious*, *Henry Jacoby*, *Queen of the Belgians*, *Mrs. Deane*, *Aurora*, *Brussels*. *Cannella* real manure is an excellent stimulant, and if given twice a week produces good trusses in abundance.—A. G. BUTLER.

Planting Gentiana verna.—Much has been written about this beautiful Gentian and the best mode of growing it, but one important fact I have not seen mentioned anywhere, and that is that when being planted it should have the soil around it pressed as hard and firm as it is possible to ram it with a blunt stick or hammer. After many failures I planted *G. verna* in this way. The soil around the plant is as hard as a throbbing floor, but the plant is evidently quite at home and has flowered most abundantly. By its side is a *Gentiana hawarica* planted in the very opposite manner in loose, spongy soil, with an abundant admixture of Sphagnum Moss in a flourishing condition. F.

PLANTING EXPOSED GROUND.

FROM experiments that have been made in many places throughout the country, it is now pretty conclusively settled that the Corsican Pine is a tree well suited for planting in cold and wind-swept regions. True, from its narrower spread of branches, it cannot compare with its nearly the Austrian (*P. anetrica*) in the amount of shelter it will afford; still, that it is equally hardy and suitable for exposed hilly ground is now well known. The very fact of its having a narrow spread of branches makes it particularly suitable for general forest planting, for, like the Larch, it seems able to grow and produce timber satisfactorily when but the top fourth of its stem is furnished with branches. Both the Corsican and Austrian Pines get the name of being had to transplant, and this is true to some extent, but not half so true as is generally stated. By lifting annually or every two years, when young and before being planted out permanently, the roots become thick and bushy, full of fibres and soil-retaining; but where judicious transplanting has for a time been neglected, there are usually but one or two large roots, and very few of the branching fibrous ones that render planting out a success. Taking everything into consideration the Corsican Pine, independent altogether of its value in a commercial sense, is a tree that is peculiarly suitable for planting on exposed ground, and may, with the Austrian, be successfully planted in the formation of woods at high altitudes, and where the ground is fully exposed to the worst winds of the particular district. The Scotch Fir (*P. sylvestris*), every mountaineer must know, is an excellent Conifer for planting at high altitudes and on poor rocky soil. Probably it ascends to a greater height in this country than any other species, while the fact of its being able to succeed in the poorest of soil is yet another and excellent recommendation. Even on gravel, and that of the unenviable "pan" class, it grows astonishingly, and may any day be noticed on some of the commons around London.

THE COMMON LARCH must not be forgotten in a choice of trees suitable for planting on the flank of the hills, but the fact of its being deciduous is rather against than in its favour. It gets heated badly about, and in the plantation to which I referred it certainly could not hold its own with either of the three Pines that have been spoken about. The branches on the worst side always become short and twisted and appear as if they had been nibbled off by sheep; but, for all that, it is an excellent tree for the purpose under consideration. The Larch is such a valuable forest tree, speaking economically, that we cannot do without it, for none other has yet stepped in to take its place, so that even if it will not succeed satisfactorily on the outside of an exposed plantation, yet inwards it is one of the best, and should be largely planted. By planting even a treble line of Austrian, Corsican, Scotch, and Mountain Pines, the amount of shelter afforded is just enough for the Larch, for then it will succeed, and if the soil is at all good, grow away rapidly. Next to the Pines mentioned one of the best trees I know of for planting on exposed ground is the American Winged Elm (*Ulmus alata*), or, at least, what is generally known under that name. All along the outskirts of a strip of woodland that many years ago was planted on one of the Welsh hills for shelter to the neighbouring sheep farms, this small-growing, wiry, tree has stood well, and clearly distinguished itself as a capital subject for planting where the winds blow hard and long. It is certainly a tree of no great pretensions, rarely rising more than 26 feet from the ground, and having thickly arranged branches that are furnished with the curious wing-like appendage, from which the name has doubtless been derived. Far and near, deep and shallow it sends out its roots, while the thick, corky bark of stem and branch seems as if purposely intended for protection.

SYCAMORES do unusually well, but they are hardly suitable for the more exposed ground, but form fine, sturdily specimens, and produce a lot of good timber when not directly exposed, or, in other words, where the first brunt of the storm has been faced by other more hardy species. Several of the Willows, and first-class trees for the exposed hillsides, good

examples of which may be seen away up in the mountains by the base of Snowden and around the beautiful lake of Gwynn and Eidwall. Then two at least of the Poplars, the Bird Cherry (*Cerasus Padua*), the Hornbeam, and the common Scotch Elm are all well able to hold their own on breezy ground at high altitudes. The Beech must not be despised, and asserts its own rights, as the grand old specimens on that Kottish peak of solid chalk, Knockholt, and which is visible for miles around, will at once prove to the sceptical. The Oak, although it gets twisted, stunted, and scarcely recognisable, is a good wind-resisting tree, and not one whit behind it is the common Alder. But about the Birch and Elder it is perhaps needless to speak, for everyone knows full well the friendly shelter afforded at meal-time by a clump of the former, while the victor to some of our wildest coasts, and where he can scarcely keep his feet, must admit that, though despised, rooted out and neglected, the common Elder is one of our most valuable shrub-like trees. A.

CELSIA CRETICA.

THIS charming and if not exactly "long lost" at any rate sadly neglected plant appears to be at last attracting some amount of attention, so that a few notes and hints on its culture may not be out of place. When it becomes thoroughly known I venture to say there will be scarcely a well-kept greenhouse or window that does not contain at least a plant of this graceful subject. Here, in Sussex, it is a favourite window plant with the cottagers, but though I have lived in several parts of the country, as well as in and near London, and always taken a great interest in this kind of thing, I had scarcely seen the plant until about two years ago. Then, although it had been grown in a few cottages for thirty or forty years, no one seemed to know what it was, but now I notice it is becoming much more common. It is a nearly hardy perennial, with comparatively few ovate leaves, thickly covered with small hairs or down. The flowers are borne in long, arching spikes, which even in quite small plants often reach a foot or even 18 inches in length, and the spikes are produced successively during the greater part of the spring, summer, and early autumn. After attaining a height of about 3 inches the young plants push up a first or central spike, and when this has flowered and died, or been cut away, others spring from its base, and others again follow these almost indefinitely. The flowers themselves, which are of a deep golden-yellow, with a curious central mass of purple and hairy anthers, are fine lobed, and almost flat. Individually they do not last long, which is a pity; but as they expand in succession from base to point of the spike, this remains effective for a considerable time. The plant, when in full bloom, emits a faint but very perceptible perfume, especially in the early mornings, which resembles the vanilla-like fragrance of some Orchids—*Onoclidium* in particular. This *Celsia* appears to thrive best in a rich, mellow soil, composed of fine loam, leaf-mould, a little very old manure, and some sand, and they like plenty of water while in full growth and bloom. They also enjoy a cool temperature, with shade from hot sun; and, in fact, succeed under much the same conditions and treatment as would suit an ordinary Calceolaria. They are easily raised from seed, and if this is sown early in the year the plants will produce the first single flower-spike in June or July, and others in August and September. They also do well planted out-of-doors during the summer. I have never been able to succeed in striking cuttings. B. C. R.

Carnation "Grsnadin."—I believe this to be the most reliable Carnation in cultivation. It is perfectly hardy and thoroughly fog and disease proof. The inclement weather that lays havoc with Carnations generally in low lying situations does not in the least affect *Grsnadin*. All other kinds I am obliged to shelter in winter, but this remains green as Grass when subjected to an ordeal that kills other so-called hardy varieties. It is remarkably showy and prolific, and produces a half a dozen two-year old plants will yield hundreds of blooms for cutting.—E. H. B.

FERNS.

POTTING FERNS.

Most kinds, both large and small growing varieties, will, before this, be throwing up their young fronds. To keep them in good condition should be the aim of the cultivator, whether it be in the case of large quantities or where a few only are grown. This desirable object may be facilitated in various ways, according to the kinds grown. Broadly speaking, Ferns are oftentimes far over-potted from some mistaken view or other of their requirements. I knew two growers of Ferns who used to keep their plants in what some would think a far too restricted condition at the root. Not so, however, for the plants were the picture of health. In one instance particularly the plants were in such small pots as to necessitate their being stood in pans similar to those used by some who force Strawberries. This was requisite to safeguard them against any oversight in watering. Some might urge that repotting would have been more desirable. That, however, would have meant increased vigour with more room required to grow them than could be conveniently spared under the circumstances. In the other instance the plants were apparently given the best of soil suited to each kind; this, combined with careful potting, had the desired results. These latter were usually in rather larger pots than the former, being more what might be termed half specimens, the plants themselves, the picture of health, being difficult to beat in competition when examples of much larger kinds were pitted against them. Those instances are cited to show, as many will no doubt have already gathered, that the overpotting of Ferns is a fallacy. This it truly is, done without doubt I do not for one moment dispute with good intentions, but, all the same, wrong in practice. For a time the plants may thrive well, and all seem to be going on as satisfactorily as one could desire, but the time comes when the soil gets into a sour and inert condition. This is not the result of the Ferns appropriating the nutriment in the soil nearly so much as it is of repeated waterings, which send the best of its properties away through the drainage hole instead of being assimilated by the plants through the roots. When a plant is potted before its proper time, the roots rush away again into the fresh soil a long time before they have withdrawn all the nourishment from their previous shift; this will tend possibly to greater vigour for a time, but decline comes all the sooner through the roots being spread over a greater space, thus not in many cases being able to absorb the properties of the soil whilst it is still in a fit condition. This

Vigorous growth for a time has to be supported, but when the season of rest (or partially so) comes round, then there is often a perceptible decline. The best plan to adopt with Ferns is to give moderate shifts only, and the better the soil, the better will be the ultimate results. Poor soil, to which some fertiliser has been added, may answer for a time and be an incentive to rapid growth, but when this is exhausted, then the plant quickly becomes impoverished unless it be repeatedly fed by some manurial agency. In the first case to which I alluded the grower used to water his Ferns with weak guano-water with the best results. Peruvian guano, when it can be had pure and unadulterated, is still an excellent manure for many pot plants. When Ferns are well potted and in a firm manner compared with soft-wooded plants in general, using good soil, the growth they make will be much more enduring. Thus treated, they can be watered far more liberally than when the soil is poor or has a tendency to be sour. I have noticed particularly when growing *Gymnogrammas* what an amount of water they will take when the soil is in good condition and, of course, full of roots. In the case of *Adiantums*, it is readily discernible whether the plants are being potted freely or left somewhat pot-bound by the size of the pinnae. For instance, take note of plants of *A. cucullatum*. When grown under what might be termed a generous treatment, that is, freely potted, the pinnae will be considerably larger, and, if they are also shaded, of a much deeper green. Such a growth is never of so lasting a character; it has a tendency to damp off if over-crowded, whilst if used in a cut state it will not last

nearly so long as well-hardened fronds from plants grown under less congenial conditions. Some Ferns, such as the *Davallias* and *Gleichenias*, for instance, are very shallow rooters, preferring to root near the surface. The creeping rhizomes of these Ferns root as they extend when they come into contact with the soil; hence shallow pans or pots drained at least half way up should be used for these and similar rooting kinds. It is not advisable to be led away with the idea that shifting a stock of Ferns is necessary more than once in a season; young quick-growing seedlings may, it is true, need the second shift, whilst, on the other hand, many Ferns with good management will stand over for two years. Even Tree-Ferns when grown on from small plants do not require such frequent repotting. Some Ferns, such, for instance, as the various forms of *Pteris cretica*, *P. serrulata*, and the smaller types of the *Aspleniums*, seem to be peculiarly adapted for cultivation in small pots. F.

THE LADY FERN (ATHYRIUM FILIX-FEMINA).

This is one of the most elegant of our native species, even in its normal condition. The Lady Fern when growing freely attains a height of some 4 feet, sometimes even more, the large,

The Lady Fern (*Athyrium filix-femina*).

finely-divided, feathery fronds being exceedingly beautiful. I cannot understand why this plant is not more grown in small suburban gardens, which sow remain bare and unsightly. Besides the normal form, as shown in the illustration, there are many varieties, a few of the best of which are named below, all of them exceedingly beautiful and deserving careful attention. It is not amongst the earliest kinds to put forth its fronds in spring. *A. filix-femina corymbiferum*: This is a hard-growing, handsome Fern, nearly of normal size, having the apex of the frond and each of the pinnae densely tasselled. It is one of the oldest recognised sports of this species, and up to the present it retains a first place amongst them. *A. filix-femina Clarissimum*: This is a very large form of great beauty; it is not crested in any way, but the pinnae are unusually long and the segments very finely cut. It does not produce young plants readily. *A. filix-femina acrocladon*: Of this form there exist many sub-varieties, all of which are beautiful. The apex of the frond is more or less densely crested with a very finely divided mass of short Moss-like tufts. *A. filix-femina Kalothrix*: This is not a fern plant, but it is one of the very handsomest forms into which the species has crested,

and were it not known to be a seedling it might lay claim to specific origin. The fronds are of large size, and the divisions of each are as fine as hair, with a peculiar translucent lustre. It requires to be sheltered from rough winds to preserve its beauty. *A. filix-femina plumosum elegans* is as other fern of exceeding beauty, but not in any way crested. The fronds are large, much broader and longer is the pinnae than those of the type, and very elegantly divided. Every lover of Ferns should grow this variety. *A. filix-femina Victorie*: In the present plant we have one of the most extraordinarily crested forms it is possible to conceive, and at the same time one of the most beautiful. The pinnae are reduced in width, so that no confusion can be detected; in fact, had the plant been grown by rule and compass, it could not have been more strictly symmetrical. The pinnae fork immediately upon the rachis, spread out, and each side pinna crosses the next one near the point, and the apex of each one has a small crest or tassel. The top of the frond has a large crest; the colour is deep-green. The plant under cultivation produces forms more or less true. Only one plant was found in a wild state in Scotland. Besides the above kinds there is an immense number of all sizes and density. Some are small kinds, heavily crested and much forked. The smaller kinds, which require an elevated situation on the rockwork, will thrive well in a Wardian case. W.

The White Lupine.—Few handsomer plants adorn the garden than the white variety of *Lupinus polyphyllus*. The type is well known, its stately spikes of blue flowers continuing to brighten the garden over a long season. It must be a poor soil or position that will not grow this stately plant, and when the white variety is seen in a bold mass it is a sheet of white. The foliage of the Perennial Lupine is elegant, but when the plant is in full bloom its beauty is eclipsed by the splendid spikes of white flowers. It may be grown in small as well as large gardens, and looks especially well when backed by an evergreen shrub to bring out the beauty and purity of the blossom. A good figure of it is given in *GARDENING* of June 10, p. 206.—V. C.

4007.—A plague of rats.—The best preventive of this serious trouble is to place chloride of lime in the haunts of the rats, as they so hate the pungent smell of this that they will decamp rather than endure it. The chloride of lime should be placed, in quantities of half a pound, under the boards, or in the drains in which the rats assemble. Probably, if the house be large and rambling, a considerable quantity may be necessary to drive them out; but they can thus be shut out of one part after another until their "castle" be known, when it might be worth while to open that part, and destroy them with dogs and ferrets, afterwards laying down plenty of chloride of lime (which is also a strong disinfectant in case of there being any dead rats about) before closing the place again. When once a large number of rats has taken possession of an old house, traps and cats are of little use, although keeping cats will usually prevent rats from returning to the house where they are.—I. L. R.

There are two or three ways of destroying rats, of which "R. W. F." may not know: 1. Traps if baited with Sunflower-seed are irresistible. This discovery was made by the keeper of some zoological gardens. Any trap which has caught a rat should be deodorised by putting it on a stove for a few hours, and on no account should it be touched with the bare hands while re-setting, as they will avoid a trap on scenting the human hand. 2. Poison should not be put down the holes, as so many people do. You should spread it on meat or bread, place it in the middle of the room with some saucers of water near, and sufficient hay or straw for the creatures to hide in, as the instinct of every animal is to crawl away to die in hiding. Strychnine or prussic acid are practically the quickest poisons, in which case soak the meat or bread in the poison. 3. Chloride of lime placed about the house near rat-holes or drains is a great deterrent, as rats abhor the sickly smell. *G. Potting Ferns*, and all seeds, if soaked in paraffin for twelve hours before planting, are protected by late N. J. A. W.

OUTDOOR PLANTS.

CATANANCHE CERULEA.

THESE charming plants, closely allied to the Lettuces family, are not nearly so often seen in gardens as might be expected, considering their showy flowers and striking habit of growth. The species figured in the accompanying cut is the most common, and although perennial in light soils, I am afraid it is at the best but short-lived, and in heavy soils at any rate gives most satisfaction as an annual or biennial. We have doubtless much to learn about the longevity of South European plants especially, and may often discard a good plant simply because it refuses to live more than a couple of years or so in our borders, when the same treatment afforded to annuals and biennials would enable us to indefinitely keep the particular species. The species in question is an excellent border plant; the everlasting-like flowers of an intense blue give it a decided character, and as it may be depended upon in a light sandy soil, it could readily be made a feature by being planted on the margins of the shrubberies or even naturalized in semi-wild places. There are a white and a bicolor form, and the three mixed together would be very effective. The stems rarely exceed 2 feet to 2½ feet high, the leaves narrow, lance-shaped, with a few small teeth on each side, and usually glaucous. The three forms are natives of Southern Europe, and were introduced as early as 1596. *C. lutea* is a hardy annual, and is similar to *C. cerulea* in every respect excepting its bright yellow flower-heads. It is a useful border plant, and makes showy patches when liberally treated. The seeds should be sown in the open border about the beginning of April, the seedlings being thinned out to the required distance, which should never be less than a foot.

THE LILY.

THE great family of Lilies reveals many charming things, from the snow-white Madonna flower, *Lilium candidum*, to the graceful *L. pardalinum* that sways gently in the breeze. It is impossible to go into lengthy details, but one general rule may be applied—that is, to have a loamy soil. Peat is not essential, and manure is positively injurious, unless well decayed and applied in the form of a top-dressing when signs are apparent of need of some stimulatory influence. The bolder types, such as *L. longiflorum*, *L. candidum*, *L. chalcedonicum*, the Scarlet Lily, and the brave Tiger Lilies will fare well on ordinary garden ground, if it is not too heavy, richer, more substantial diet being given to *L. anatum*, *L. martagon*, and *L. Humboldtii*. We are not, however, supposing that every kind of Lily will find a place in the amateur garden. A few of the less rare species and varieties, will be amply sufficient to fill the *parterre* with colour and fragrance. Large gardens usually have Rhododendron beds, and it is in these that Lilies do well. Visitors to the Royal Gardens, Kew, in the month of August and throughout the autumn will see a Lily show, the Auratums sending up their burden of flowers above the Rhododendrons, and it is precisely for this reason that a kind of brotherhood exists between the two very opposite families that such success is achieved by the combination. Peat and loam suit both the shrub and the flower, and the bronchos act as a shelter to the rising Lily shoots in spring, which when exposed are apt to suffer severely from sharp frosts and cold winds. The propagation of Lilies is accomplished by either division, or rather moving the offset bulbs from the main bulb, and bulbs in the axils of the leaves. The family of Lilies presents diverse complexions in flower, leaf, and habit. *L. pardalinum* runs up over 6 feet in height; but some of the varieties of *L. davuricum* grow only a few inches. A useful selection for the garden would be *L. bulbiferum*, *umbellatum* (scarlet-crimson, in which there is a shading of yellow), the Scarlet Turk's Cap Lily, *L. chalcedonicum* (rich scarlet, very showy in cottage gardens in July), the common Orange Lily, *L. croceum*, *L. davuricum* (rich crimson, delightful in the shrubby border), *L. martagon*, a favourite with all who care for Lilies, *L. tigrinum*, the gorgeous Tiger Lily, and *L. speciosum*, of which there is a very charming white variety, *L. Thunbergianum*, and its long train of dwarf forms, and *L.*

auratum, the king of Lilies, may be grown with freedom, the last mentioned in particular. It is one of the most precious plants from Japan, and the enormous sale of bulbs each year in London is sufficient vindication of its popularity and splendour. The Lilies are now blooming freely, and those who wish for a good selection cannot do better than select from those named. Bold clumps of the flowers in the garden in the summer months are remarkably attractive, and to get a good effect there must

Catananche cerulea.

be a mass of colour. Single spikes are not showy, especially of the quickly coloured kinds.

C. T.

4033.—*Sempervivum tabulaeforme*.

—This is a tender plant of a singular form of growth, as the name indicates; but when it is in flower it is not to be despised, and the flower-stem rises from the centre, and if the plant is well grown it assumes a perfect pyramidal form that is very pleasing, as there is a certain degree of gracefulness about it that one would not expect to see in such a pancake form of plant before it commences to flower. Seeing that you have so many plants in one pot, you had better plant them out in the garden at once. It is possible that one or more of them may flower this year; but as they are so poorly grown you will not get a correct idea of its beauty as a flowering plant. Any that do not flower you may take up again in the autumn. I grew hundreds of these plants about fifteen years ago to associate with other succulents, and, if I remember right, the plants flower when they are three years old, and then die. When the seed is properly matured it grows freely, and the second year the plants will be as large as a cheese-plate, and quite as flat.—J. C. C.

— This may be planted out for the summer, and in a bed of succulents will be useful. It may be lifted for the winter and kept moderately dry. It is used for bedding in the park, and is best adapted for such a purpose.—C. T.

4038.—**White-flowered plants for cutting.**—You do not say whether you require indoor or hardy flowers; if indoor, and you can force them, nothing is better than *Spiraea japonica*, White Polargonium, *Lapageria alba*, a fine massy white flower for cutting; *Bouvardias*, as Alfred Neuner, double white, *Vreolandi*, or *Humboldtii*, corymbiflora *Camellia alba plena*, *Calla ethiopica*, *Staphanotis floribunda*, and *Carex* of the tree class, as *La Belle*, very pure, *Mlle. Carlé*, or the *Malmaison*. But this is only a small selection of white flowers that may be got in the first half of the year. As, however, you mention Pinks, possibly you require hardy plants, if so, you might select White Pyrethrum, which could be in bloom just before the Pinks, and they last well when cut. Both single and double kinds could be chosen. A very lovely flower for cutting early in the summer is the White Snapdragon, known botanically as the *Antirrhinum*. It is as easy to grow as any of its kinds, and the flowers are pure-white. You should certainly make a good note of this. Then you could have the white variety of *Campanula persicifolia*, a very handsome and easily grown plant which has been recently commented upon

in GARDENING. There are many very beautiful hardy plants with white flowers suitable for cutting. The *Achilleas* are a host in themselves; they bloom in the summer months. *A. mongolica*, *A. The Pearl*, a lovely flower quite double and very pure, *A. ptarmica fl.-pl.*, are all hardy and vigorous plants, well adapted to be grown freely for cutting. Than for the autumn months nothing excels *Anemone japonica alba*, a very vigorous plant, strong in growth, and if given a top-dressing of well-decayed manure each year, the display of flowers will be more profuse. A good mass will produce a large quantity. Then you might have the white-flowered *Aquilegia*, a very fine thing that is in beauty before the Pinks, and amongst the *Campanulas* or Bell-flowers there is a host of subjects available; the white *Canterbury Bells* being of note. Then there is a variety of *Chrysanthemum leucanthemum* named *simplex*, which is very pretty, and for the late spring *Trillium grandiflorum*, the *Wood Lily*, a very distinct and beautiful thing, the flowers pure white, and in a setting of deep-green leaves. The *Candytufts* have in many cases white flowers, but they are not so well adapted for cutting as many of the kinds mentioned above; whilst you may also select *Lethyrus albus*, *Lupinus polyphyllus albus* (the White Perennial Lupine), *Malva moschata alba* (the White Mallow), *White Daffodils*, particular varieties of *Narcissus poeticus* for early spring, and the double *Fair Maids of France*. Other things might be mentioned, but those are all of merit, and indicate the large selection of white-flowered hardy perennials available.—C. T.

— After the bulbe are over, then comes a sort of break among the white flowers useful for cutting till the *Pink Roses*, &c., comes in. White flowers there are, of course, but all have not the same value. *White Forget-me-nots*, *Lupinus polyphyllus alba*, *White Pyrethrum*, including *Mont Blanc*, *White Herbaceous Pinks*, *Clematis montana*, *Double White Rockets*, and the *Evergreen Candytufts* are all more or less useful. *Ranunculus aconitifolius plena* is a good thing for cutting; and I have had the white variety of *Clarkia pulchella* very early and useful from autumn-sown plants. *White Brompton Stocks* are nice for cutting.—E. H.

— *Anemones* of sorts would be useful, especially the white varieties of *A. coronaria*, *A. alpina*, &c. Several of the white-flowered *Narcissus* should also be grown in quantity, such as *N. poeticus*, *N. p. ornatus*, and the fine old double white kind. *White Myosotis* (*Forget-me-not*) is also nice, and *Campanula persicifolia alba plena* is a lovely power for cutting that, if planted in a warm position, will often flower before the bulk of the Pinks.—B. C. R.

4035.—**Lilies and Irises.**—You can make your border a picture of colour with Irises and bulbe. As to the first, it depends upon what you are prepared to spend, as the Iris family is a large one and embraces expensive and cheap kinds. The following, however, are beautiful and not extravagant. For blooming quite early in the spring you have the violet-scented *Iris reticulata*, a very beautiful flower, deep-blue in colour, and with a strong fragrance of Violets, and amongst the German Irises there is a wealth of beauty, a selection of the best kinds being given quite recently in GARDENING. I need not therefore repeat this selection, but everyone mentioned is of merit. Keep to this selection, otherwise you will get a lot of poor coloured varieties that will disappoint. I should leave such ones as the *Onocycelus* alone. They are not for beginners, and this class includes the curious *Mourning Iris*, *I. pincea*, yellow, very rich and pretty; the late growing *I. ochroleuca*, the flowers white and yellow; *I. sibirica*, the *Siberian Iris*, a graceful-leaved species with blue flowers, also its variety *alba*, white, and the English and Spanish Irises may be mentioned. Both these sections give a wealth of colour, the flowers varying from white to deepest purple. The latter blooms a week or two before the former and thus provides a succession. The lovely *Kiemperi Iris* requires more moisture than I should think you could afford to give it. It is very charming in July when it flowers at the margin of winter. At the foot of the wall plant the quite late autumn or early winter-flowered *IRIS* which has foliage not unlike that of a Beet in miniature.

Of course, there are many more hardy than these, but you give no particulars as to the size of the border, or the number of lilies you require. The early-flowering species or varieties are many in number, but some are expensive. I have mentioned the more popular kinds, and except *L. alata*, and *L. reticulata*, they bloom in early summer, the great season for this family. The lilies that I should recommend would be the White *L. caedidum* that blooms in June. It has unfortunately been much subject to an invidious disease, but still you should try it. Its white fragrant flowers are very precious. *L. bulbiferum*, the well known *L. croceum*, the early June-flowering *L. umbellatum*, a showy, vigorous kind; *L. elegans* in variety, particularly the quite dwarf kinds, the flowers varying in colour; the Scarlet Martagon, *L. chalcedonicum*, *L. Martagon*, which has, however, a too powerful scent—but perhaps you will not mind the unpleasant odour; *L. auratum*, very beautiful in August, and too well known to describe; *L. speciosum* or *L. laeifolium*, as it is sometimes called, blooming in late summer and early autumn; the Buff Lily (*L. testaceum*), and the Tiger Lily (*L. tigrinum*), in variety, a superb flower for colour. This will form a very good selection to commence with, as of the species mentioned there are many varieties.—C. T.

— *L. caedidum*, *L. Martagon*, and *L. tigrinum*, and the varieties of these species are all good and are sure to do well. If I were only just beginning to grow lilies, I should get all the varieties of the above three species, and grow them well first, and gradually introduce others. These are most of them cheap and hardy, and might, for the most part, be planted in the town garden. For lilies I should recommend the English and the German. The last named are evergreen, and both families are remarkably pretty and very cheap.—E. H.

4032.—Cut-flowers.—Pyrethrums (single and double), *Asterium*, and *Gedelia* should supply your needs. Although *Gedelia* has a flimsy appearance, and when the plant shuts up every evening, it is one of the best flowers in existence for cutting. The fact of separating it from its parent stem seems to paralyse it, so that it forgets to close up at night, and its decay seems to be arrested; indeed, I have known it to stand in water for a fortnight before it faded.—A. G. BUTLER.

—The variety of Yarrow (*Achillea millefolium*) named roseum is of the colour suggested by the name; then if you have a warm, sunny, sheltered border, such as skirting a wall of a plant-house, you might have the Belladonna Lily (*Ameryllis Belladonna*), which has rose flowers, also *Anemone japonicum*, not alba, the type bearing rose flowers, *A. fulgens*, well known for its bright-crimson colour, the crimson-flowered Snapdragon, Sweet William, Thrift or *Armeria*, excellent as an edging, and may be cut, Michaelmas Daisies of this colour; for the autumn, Indian Pink, *Carex*, of these shades of colour, *Dielytra spectabilis*, or the "Lyra flower," Foxglove, Scarlet Lychnis, *Proseis*, particularly the old double crimson and the blush varieties, *Pentstemon* in variety (there are several that have flowers of this shade), *Phloxes*, herbaceous varieties in particular, *Pyrethrums*, *Schizostylis coccinea*, *Spiraea palmata*, the flowers rich-crimson, and, of course, various hardy bulbs. All the above named plants are quite hardy, not difficult to grow, and bear flowers in one or other variety of the shades of colour that you require.—C. T.

—Roses of several sections and many varieties, if planted in warm and sheltered positions, on sunny walls, &c., will generally commence flowering early in June. *Aconitum fulgens* and several of the varieties of *A. coronarium* will also be found extremely useful. *Dielytra spectabilis* is very graceful, and lasts fairly well when cut and placed in water, and a shrub that everyone ought to grow for cutting from is the exquisite *Weigela rosea*.—E. C. R.

—Pyrethrums and Paeonies are among the most beautiful things for June cutting. To these may be added Red Pinks in variety, Oriental and other Poppies, but this season the Oriental Poppies went off very quick, but the same hot summer which hurried those away brought on the Shirley Poppies. Red Lothian or Brompton Stocks will be useful.—E. H.

THE HARDY ANTHEMISES.

ALTHOUGH a large and comparatively showy genus, very few of the species find their way into cultivation, and of these few perhaps the most popular is the species in the accompanying cut. Many of the species are free blooming and showy, and will be found very useful where flowers of the Marguerite class are in demand. Only two of the alpine species known to us are to be found in gardens. *A. Aizoon*, with its silvery leaves and white starry flowers, is fairly well known, but *A. Biebersteinii*, a grand species from the Caucasus, is rare, and although one of the most beautiful early summer rock plants, it does not seem to be very common. They are both easily managed compared with many of these plants from high altitudes, requiring a warm, sunny position, and a deep, light, rich soil. They may be increased by seeds, cuttings, or division—the former as soon as gathered, cuttings in July and August, and division in early spring.

A. AIZOON.—A charming dwarf growing rock plant, rarely exceeding 2 inches to 3 inches in height, has a compact or tufted habit, the loose rosettes of long silvery leaves looking well in winter as well as summer. The flowers are produced in abundance during summer, white, and somewhat resembling a large Daisy. It is a native of Northern Greece.

A. BEBERSTEINI.—A rare species, and from specimens growing in the rock garden at Kew, one to be noted and eagerly sought after. It forms dense mats or carpets of short silvery leaves, narrow, and more or less deeply cut. The flower-stems, which are numerous, are about 9 inches high, each bearing a very large golden-yellow Marguerite flower, almost as showy as that of the fine *Arnica montana*. It flowers from April to July, and is a native of the Caucasus.

A. TINCTORIA is of an entirely different

OUR READERS' ILLUSTRATIONS: The Yellow-flowered Chamaemelum (*Anthemis tinctoria*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Wolley Dod, Edge Hall, Malpas, Cheshire.

character. It may be classed as a herbaceous perennial, and when done well is one of the most beautiful objects in the autumn garden. It is so hardy and requires so little attention that large groups in the wood or wild garden would soon increase and make a grand show. Its compact and dense habit would keep the undergrowth from interfering with it in any way. As a border plant, or even in beds, it has few equals. Its bushy habit, fleshy cut, fern-like, dark green foliage, and abundance of bright yellow flowers (as shown in cut) make it a very attractive and beautiful object. It flowers all

through the autumn months, and is a native of Europe.

Others are *A. Kitchellii*, *A. nobilis*, with white flowers, *A. arvensis*, &c. D.

A note on Hollyhocks.—We welcome back to life again the stately Hollyhock, almost lost to us by the visitation of disease, a kind of fungus, that for a time banished its presence from English gardens. Years ago, before the plague made its appearance on English soil, the Hollyhock was grown and exhibited in all parts of the British Isles, but the cloud of disease over-shadowed its stately spikes, killed outright many of the old varieties, and threatened to exterminate every vestige of Hollyhock from our gardens. It seems, however, to have outlived this remarkable plague, and once again nods over the weeden fence in the cottage garden, and lends dignity to the larger domain. One reason of the peculiar severity of this disease was that the plant, through hard propagation, had become in a sense weakened. It was the fashion to strike the cuttings in a high temperature to get a stock quickly; but the effect of this was to weaken the constitution of the plant, and ill fit it for such a severe attack of a virulent disease. The secret of success in the culture of the Hollyhock is to grow the plants well, providing them with a very rich soil, which should be deeply dug, and incorporated with it plenty of manure, whilst in the case of plants whose spikes are desired for exhibition, weak liquid manure water occasionally will promote the development of splendid blossoms. Stagnant ground in winter is fatal; but it should not be too dry in the summer months, whilst division of the roots is a ready way to gain an increase of stock. Besides division, there are two other ways of propagation—by seeds and by cuttings. These may be taken in spring, placed in pots filled with good soil, and given slight heat, such as that supplied by a hot-bed. When rooted, pot them off, and transfer to a cold frame before planting them out in the garden. If the plants are propagated in the summer, keep them in a cold frame during the winter, and plant out in the following spring. They will bloom well the same year. A good time to sow seeds is as soon as they are ripe, which will be in the autumn, treating them similar to half-hardy annuals, and giving them a little heat. Let off the seedlings in due course. Keep them during the winter in a frame, and plant out in the ensuing spring. When in the beds during the winter they are, if very young, likely to succumb to the trials and privations of English weather in that capricious season. Even when cutting down in the autumn the old stems, after the festival of flowers has been held, leave them of moderate length, so as to preserve the crown as much as possible from the influence of damp.—V. C.

Sweet Peas.—This lovely flower has been increased in interest of late years by the introduction of several very beautiful varieties, that give considerable range in colour, and have lost none of the good qualities, the sweet fragrance, and freedom of the old kinds. The Sweet Pea is not rightly grown, as a rule; it is not used in the best possible way. A few bold clumps are very pretty, but we want something more from such climbers. I lately saw quite a bank of them—a screen, shutting out an objectionable feature in the garden, and the plants fulfilled the object in view. They grow easily from seed, and bloom freely and continuously if not allowed to form seed. Masses of them trailing over twiggy sticks in the border, or running over a hedge, are very pretty, especially when a good selection of varieties is made; and all know the beauty of the tenderly coloured, fragrant flowers when arranged in a bowl or vase in the house. The "invincible" kinds are very pleasing, the scarlet, carmine, and so forth, but a few mixed varieties may be mentioned. Apple Blossom is one of the sweetest; its large, headsome flowers are white, with the wings delicate-rose—a charming contrast. It may be used for posies for its soft colouring. Butterby is another gem, the flowers white and lavender. Cardinal, one of the most recent acquisitions, is brilliant scarlet. And to these may be added Beatrice (rose-crimson), Boreator (rich-maroon), Imperial Blue (a good, distinct, and net dingy colour), and Princess of Wales (delicate blue and white).—V. C.

HOUSE & WINDOW GARDENING.

BRITISH FERNS FOR A ROOM.

THERE are many sitting-rooms with a rather sunless aspect, or in which the blinds are kept down a good deal, where flowering plants will not thrive, and yet some graceful greenery is needed to set off the cut blossoms in vase or glass. For this situation nothing is better than our own British Ferns, many of which are extremely handsome, and now that they have received a little of the attention they deserve there are many very desirable new varieties (some crested and with divided fronds) which make charming plants for a room, while they are quite hardy, and are much stronger in constitution than their foreign cousins. They can be grown to perfection in an area, and lifted into the sitting-room when in full beauty, for they need a cool, damp place without draughts when they are unfolding their lovely fronds. If an area be not available a flat bath or tray, with a layer of damp Moss in it, or Cocoa-nut-fibre, should be placed in a bath-room, or any shaded place, in which the pots may stand at night, surrounded by the moist air arising from the Moss or fibre, which should always be kept damp, and free from the dust and draughts of the sitting-room when it undergoes in the morning the necessary process of brushing and airing. Several beautiful cultivated varieties of the common Hart's-tongue Fern (*Scopolopodium vulgare*) are now to be had, and these are especially valuable, being evergreen, so that they are available for room decoration during the winter months. Another very elegant evergreen Fern is *Asplenium Adiantum-nigrum* (the Devonshire Black-stemmed Fern); it is smaller than the *Scopolopodiums*, but has remarkably pretty fronds, much serrated, and of a brilliant shining-green tint, set off by its dark stems. For larger specimens during summer there are few more beautiful Ferns than *Athyrium Flix-fumina* (the Lady Fern), also varieties of the *Laetrasia* family, remarkably elegant, and growing to a considerable size. All Ferns do best in a mixture of peat (not too finely divided) and leaf-mould, with silver sand enough to make the compost light, and a slight admixture of charcoal (burnt wood-ash) is very beneficial, and the plants must not be very tightly potted. In potting Ferns it is necessary to give plenty of drainage, and this should be covered with a little Moss, dipped in soot, to keep out insects, and prevent the drainage from becoming stagnant. Ferns after being potted often lose their fronds, and look very wretched for some weeks, but this need not discourage their owner, as they are only untidy for a time, when, if they have been kept in a damp, cool place, they will throw out fine new fronds, and take thoroughly well to their new quarters. Plenty of water should be applied to them, and if grown out-of-doors the pots should stand on fine ashes, which can be kept in a damp state, to supply the surrounding moisture which Ferns need. I. L. R.

ZEA JAPONICA VARIEGATA (JAPANESE MAIZE) FOR A ROOM.

ONE of the easiest, and at the same time most satisfactory plants to grow in a window (as a change from the ordinary run of room-plants), is this elegant Japanese Maize, with its graceful outline, giving something of the effect of a fountain in shape. The seeds germinate quickly and easily in warm weather, especially if covered with a bell-glass or tumbler until they are an inch or two high, when the glass should be gradually raised, and may soon be dispensed with altogether. The easiest plan for an amateur is to put one good firm seed into each small pot of sandy soil, and put the little plants on as they require it, never allowing them to become pot-bound. They grow so fast, and are so pretty from their earliest stages, that they are always ornamental, but when they reach their full height of 3 feet or 4 feet, and are crowned with their graceful plumes of blossom, the effect is remarkably elegant, and they stand well in a window (on the floor), or in the summer fireplaces, as a background for flowering plants and Ferns. They are also very effective in a balcony or verandah, but must be protected from very strong winds, which sometimes break them down. Good rich soil is necessary for the Japanese Maize (after the first

stage of growth), and they enjoy a rich mulch of compost laid over the surface of the soil to nourish their surface-roots. Plenty of water, too, is needed for their nourishment, and they must never be allowed to become dust-dry. Soot-water (easily made by brushing down some soot from the chimney, and tying it securely into a hit of coarse canvas, which should be deposited in a pan of soft-water), should be given them once or twice a week in a thin and clear state, the water surrounding the bag of soot alone being used, when more water can be added while soot remains in the bag, giving it an occasional stir with a stick. I. L. R.

3991.—**Creepers for a wall and plants for boxes.**—The best creeper for a north-east aspect are the *Oleiro de Dijon* Rose, *Clematis montana*, with white blossoms, flowering early in spring; *Ampelopsis Veitchi*, with magnificent autumn foliage; the winter-flowering *Yellow Jasmine* (*Jasminum nudiflorum*), and various handsome kinds of Ivy. For the north-west a more delicate set of creepers may be selected if the situation be a sheltered one. William Allen Richardson Rose or the *Red Glory* (*Marie Henriette*) may be tried, with the larger-flowered varieties of *Clematis* (C. Jackman and many others), *White Jasmine*, *French Honeysuckle*, *Virginian Creeper*, and a *Banksian* Rose. But if the aspect be more northerly than westerly, the latter will not thrive; it also requires shelter from high winds. For window-boxes at the same aspects many plants may be selected; in fact, few will not thrive at one or the other. Tuberous *Begonias* well hardened off will do well with the morning sun only of the north-east aspect, and they make admirable plants for a box if the drooping, neat-habited double varieties are grown. The trailers in front of them may be either *Blue* and *White Lobelia*, used alternately, or *Nierembergia gracilis*, with the rich-bronze lace of *Saxifraga sarmentosa* alternating with its delicate masses of bloom. *Tropaeolum canariense* (Canary-flower) makes a charming creeper for the ends of boxes, being easily trained on string, with a few stout nails, to form an arch over the window. It will grow well in a north-east aspect, either for boxes or walls, and is very useful to cover bare walls quickly, though it only lasts till the frosts come in autumn. For the north-western boxes Ivy-leaved *Polargoniums* (pink and white or carmine and white) may be grown, which will trail down over the box in great beauty if strong plants are selected; or *Calceolarias*, *Zonal Polargoniums* ("Caraniums"), *Lobelias*, *Petunias*, and *Marguerites* will all do well here, although they may not bring quite such a profusion of flowers as in a sunnier aspect. Much depends, however, on the soil provided for them, and the daily care they receive. Plants in boxes need plenty of nourishment, and must have a good compost to start with, and the box should be drained with crocks and ashes, and not overfilled, so as to allow room for a plentiful supply of water, which will be daily needed. Most plants in boxes are more or less starved; they need much more moisture in that exposed position (crowded together as they must be for the sake of effect) than when they are in separate pots or in the open ground, and they should be syringed or watered with a rose every evening during dry weather. A top-dressing of rich compost laid over the surface soil once or twice during the summer will help them much, and liquid-manure in a very thin, clear state will suit them once a week. Soot-water (easily made by tying up a little chimney-soot in a coarse canvas bag, and placing it in a pan of water) is one of the best of liquid-manures where the plants grow in or near a dwelling-room, as it has no impure odour, and is most health-giving to the plants. If it is not possible to give all this attention to the plants, very pretty and cheap arrangements may be made by growing in the boxes a mass of the common *Nasturtium*, which does best in poor soil, and is hardy in constitution, so far as the question of constant watering is concerned. The Dwarf *Tropaeolum*, with flame-coloured flowers and deep bronze foliage, makes a handsome variety, and if well selected the result is very good. An edging of the new Hybrid *Mimulus* tones well with *Tropaeolums*, and this will grow in a very unpleasing aspect.—I. L. R.

3992.—**Early Fuchsias for window culture.**—Fuchsias will succeed in a window

through the summer if kept carefully watered, and not exposed to cold draughts. A very good variety for this purpose is *Earl of Beaconsfield*, which has very bright, long-tubed flowers. From experience I have found this very free and strong in growth. One of the best is *Sun Ray*, which has very brightly variegated leafage, keeps its colour well, and is not "spotty." A useful double kind is *Miss Lucy Finnie*, which is very free, the flowers quite double, yet not ungainly or grotesque, and pure-white, the corolla and tube rod. *Rose of Castilla* is a good kind, the flowers with white sepals and petals are purple-coloured corolla. Try *Ma. O!* and *Mrs. Rundell* are also worth notice.—C. T.

—*Mrs. Merball* (light), *Sourcity* (dark), and *Rose of Castilla* (purple and white), are, I should say, three of the earliest-flowering Fuchsias in cultivation. Of the last-named the improved form is superior to the old type. *Lady Theobald* is also early, and a very free and elegant variety.—B. C. H.

FRUIT.

EARLY CHERRIES.

CHERRIES are not grown so much as standards and pyramids in gardens as formerly, owing to various causes. Of late years, choice varieties have suffered badly from canker, and as the tree flowers so early the bloom is frequently injured by frosts, so that a poor crop is the result, while birds in most gardens are so troublesome, that only under the most favourable circumstances can a crop be secured. In orchards with a quantity of trees the last named difficulty can be minimized by earing, but does not pay with a few isolated trees, so that there is no better plan than wall culture, as the trees can be protected from frost and from birds by netting. One great advantage with wall trees is the long time the fruit will hang without shrivelling if the trees are in a healthy condition, with ample foliage and kept clear of black-fly, which is a great pest, and attacks most Cherries on walls. Unless stringent measures be taken in time, the whole crop is disfigured and the trees crippled for the following season. By planting Cherries in different positions a supply of fruit can be kept up for a considerable period. The earlier kinds, when planted on a warm south wall, will give nice dishes in June. One of the best is *Early Rivers*, a large shining black handsome Cherry (indeed, one of the best of all the black kinds) of rich flavour, with a great quantity of flesh and but little stone. It is equally good indoors or out, and the tree grows vigorously, rarely failing to bear a heavy crop. It is a seedling from the *Early Purple Gean*, a good old variety. The fruit of the *Early* (lean is richly flavoured, but the tree is very delicate and does not do well in many gardens. The *Early Frogmore* *Bigarreau* is another valuable wall fruit that can be relied upon, and though classed as a second early kind, with ma on a warm wall it ripens during the second week in June in a good season. The tree is a vigorous grower, of good constitution, and an abundant bearer, and if only two or three varieties of Cherries are grown this one should find a place. It does not canker so badly as some kinds, and keeps well if there is not too much moisture at the roots after the fruit is ripe. *Governor Wood* is also a favourite variety. It is a large pale-red fruit, richly flavoured. It is a useful variety for

WALL CULTURE, and equally good for pot or indoor culture. This last named is not quite so hardy as others, and to do it well it must have a warm wall, as in cold districts I have found it gum badly. On my light soil in a sheltered corner it crops heavily and makes plenty of clean wood. *Belle d'Orleans* is an early rich fruit of medium size. It comes into use early in June, but I prefer *Early Rivers* to this variety. *Early Lyons* is also superior, and a free grower and heavy cropper. *Bigarreau*, commonly called *Amber Heart*, is a sterling variety, and one of the best wall Cherries grown; my trees are old, and bear heavy crops of fruit of rich flavour. This is grown in quantity in Kent and other counties as a standard for orchard culture. The fruit on a south wall is large, red and yellow in colour. The tree is very hardy and vigorous and a great cropper. Though one of our oldest and best-known Cherries, it is worth wall space in every garden. This is a good variety to plant on a north wall, as it gives a later crop and is a free grower on that aspect. *May Duke* does equally well on a

north aspect, and should be included in the list of good early kinds. Duchesse de Pallau, a large dark-red kind with a brisk flavour, is a good north wall variety to form a succession to earlier kinds. Bigarreau Banmann's May and Belle de Choisy are early kinds, but I do not think they are so good for general cropping as those more fully described. For later purposes we have a wider selection of excellent kinds. The great drawback with these fruits is that the choicer early thin-skinned varieties crack badly in wet seasons. If the heavy rains can be thrown off them when fully ripe they last in condition much longer. On walls this is more readily done. I use the Vine-border shutters or corrugated zinc cover for the purpose. In dry seasons when the trees are swelling their fruit, moisture is equally necessary, or the fruit fail to swell and are soon attacked by black-fly. A good mulch early in May of decayed cow-manure greatly assists in the swelling of the fruit on light gravelly soils, as the trees do not thrive long in such positions without good feeding. With the roots in a good depth of loam less manure is required, but drainage is necessary, and in all cases the roots of Cherries should be kept as much on the surface as possible, and be encouraged to come to the top by feeding with liquid and top-dressing. When this is seen to there will be less loss of trees from canker and gumming, a freer growth being secured if due attention is paid to summer pinching of the shoots and extension of the main branches. G.

LAYERING STRAWBERRIES.

THE preparation of a stock of plants for growing in pots next year, or for making new plantations in August or September, should be no longer neglected. Where so many persons fail in growing Strawberries in pots is by making too late a start in securing the runners. It is not possible for late plants to make vigorous crowns and mature them afterwards. It is the same with plants out-of-doors. Those planted before the end of September will, if strong at that time, give a fair crop of fruit the following year, but those planted during the winter or spring will not produce any the first season. Plants in the garden that are allowed to fruit do not give early runners in quantity. My plan is to put out a few plants of the sorts required at the end of September when sufficient have been obtained for pots and outdoor supply, especially for giving an early and full crop of runners. I choose a position just within a Box-edging of one of the fruit borders, Gooseberries for instance. Here the runners are easily layered into pots and are convenient for watering; the soil is not carried off the quarters on to the paths as in the case of layering between the ordinary rows. I plant these runners 10 inches apart and 8 inches from the Box. The plants are not allowed to fruit, but are induced to throw out early runners. Fill to within half an inch a sufficient number of 3 1/2-inch pots, with loam two parts, and partly decayed horse-manure one part. Make the soil firm in the pot, placing but one crook at the bottom, merely to retain a free water passage. Plunge the pots up to their rims in the ground near the runners. Fasten one runner on the top of the soil in the pots with a small peg thrust into the soil, or by laying a stone on the runner immediately behind the leaves. If there are plenty of these early plants, without requiring to take a second on the same runner, cut off the runner directly beyond the leaves to induce all the strength to enter into the one plant on each runner. If more are required, as many as half-a-dozen can sometimes be obtained from one, so freely do they branch from strong and early runners. The soil in the pots must be kept moist to induce roots to form quickly in the soil. When the pots are nearly full of roots, sever the plants from the parent, and either plant out in their permanent quarters, or place them in their fruiting-pots if required for that purpose. It is a waste of time to allow the plants to wait longer in the small pots after they are well supplied with roots. An early start in the ground or in the fruiting-pots means a lot towards obtaining success the next season. S. P.

A good Gooseberry.—One of the best Gooseberries is Roseberry, a little green kind, very sweet, prolific, and a splendid dessert fruit

when ripe, whilst it makes good pies. I saw lately some bushes of it perfectly laden, and the flavour of the fruit, whilst sweet, is refreshing and not insipid. The old Warrington is another good kind, also the Champogne, and such sorts as these are far better than the big, watery, coarse fruits that are often seen at exhibitions. These are of no use for the table, although they may be thought much of for their size. One needs to discriminate carefully in the selection of all fruits, as the lists are filled with kinds that are not worth ground. Rosebery is, I believe, not a common kind, but it is worth a place in the gardens of all who want good table fruits.—C. T.

THE LARGER APPLES.

THESE form a considerable class of themselves, but by far the larger number of them belong to the cooking section. This is, in fact, as it should be, for nothing beyond a medium-sized fruit is desirable for the dessert. The larger Apples are most useful in their respective seasons, either for baking whole or for the well-known dumplings. Apples of large size (or rather under) are not so much wasted in paring, relatively speaking, as the smaller ones; hence

Apple "Warner's King."

they are in that respect rather desirable than otherwise. When speaking of "larger" Apples I do not allude to those of abnormal size, brought about by other than ordinary methods of cultivation. These may in their way be all very well, and as specimens of high-class cultivation reflect great credit upon the growers of such, but these fruits of extra size will not, when extra attention in labour is considered, proportionately recompense the cultivator. Those Apples which attain to a large size without more than ordinary attention are certainly most desirable, when the sorts are of a relatively good constitution, and at the same time reliable croppers. Of such is the Warner's King, otherwise known under the synonyms of D. T. Fish and Nelson's Glory, well illustrated in the accompanying engraving. This Apple is in good condition for use from October to January. When generally shown in October at the autumn fruit shows, it is of a fresh green colour, but a few weeks later on the fruit changes to a rich-yellow shade. The tree is a vigorous grower and a good bearer, being suited to either pyramid or standard culture, and is less liable to disease than some kinds. Belonging to the same category is Golden Noble, a truly noble Apple, and, considering the many years it has been in cultivation, a name that should receive far more recognition than it has hitherto done. Cox's Pomona is

another reliable kind for autumn use, and small examples of this when well coloured may be used for the dessert. Stirling Castle and Echlinville Seedling are two free-bearing varieties. Stone's Apple is of handsome appearance, bears early, not making too much wood. Waltham Abbey Seedling is another first-class Apple; this was formerly confounded with Golden Noble, but it is quite distinct from that kind. As an early sort Alexander is to be recommended as a good orchard variety. Winter Hawthornden is larger than the old variety of the same name; also a good cropper. Alfriston is an excellent late kind. Two first-rate Apples of recent introduction are Bismarck and Sandringham, both of which should be seen more in a few years when better known. Peasgood's Nonsuch is a very fine-looking Apple, but I doubt if it can be classed as a good keeping variety. J.

EARLY PEACH "AMSDEN JUNE."

THE above variety is useful on account of its earliness, its free-bearing varieties, and good flavour. Some good Poach growers may not agree with me in my estimate of this variety—and here let me remark I am only speaking from my own experience, as I do not think it is widely known and is not often planted indoors—but it deserves a place, as when it succeeds well it is not inferior in flavour to older and good-flavoured varieties. I may state I prefer it to Alexander and Waterloo, both of which are American introductions of late years, and here, no doubt, many will not agree with me, as Alexander is supposed to be the best of the trio; but with me it does not do nearly as well; it certainly blooms well, but more than three parts drop; indeed, all the first flowers never set; only a few late blooms and smaller flowers set. It is wonderful how soon these late flowers set and swell up, finishing long before the older kinds are ready. I do not depreciate Alexander on any other account, as it is really a valuable early Peach, but its erratic behaviour when in bloom causes much uneasiness and a thin crop at the best of times. Waterloo is much liked by some, but I prefer Amnden June. I grow Waterloo in pots better than planted out, as I get more colour in the fruit. It is quite six weeks earlier than some of our good sterling kinds. For outside culture it is very good. The great value of these early Peaches is that they can be forced readily, thus prolonging the season greatly. I formerly grew Early Beatrice indoors, but the fruits are so small that they are not to be compared with the above kinds. One point worth recording is that it is best to force slowly till the fruits have set; then there is less danger of dropping, as they will stand more heat later than is often given if not hurried too much at the start. For instance, Amnden June last season was ripe in fifteen weeks from the day of shutting up the house, and at the coolest end, this latter being greatly in its favour. Some think these early Peaches, such as Alexander and Amnden June, one and the same, but Amnden June is distinct in colour and sets much better than Alexander. Amnden June colours all over with the least difficulty, whilst Alexander requires more exposure. I prefer Alexander to Hale's Early for a cool Poach-house; indeed, those who have late houses would find these varieties useful, as they then get the treatment they like. Alexander is earlier than Hale's, though much like it in appearance. For outside culture Hale's Early is very good, but it is, I consider, less suitable for forcing, as being later than those named. We have Dr. Hogg, Early Grosse Mignonne, and others that cannot be replaced for their good qualities to succeed the early kinds. With me the Amnden does much best, sets freely, comes of a nice size, and is always of a good colour; therefore, I have no hesitation in recommending it for a few early dishes of fruit. G.

4037.—Treatment of an Apricot.—The root-pruning was not efficiently done, or the Pear-tree would not make such luxuriant shoots; most likely the tree has a strong tap-root; if so, until this is severed it will be useless to expect fruit. Do not give the tree manure in any form at present until the conditions are altered for less growth and fruit.—S. P.

THE KITCHEN GARDEN.

BRUSSELS SPROUTS.

The Brussels Sprout is no doubt the best winter green vegetable we have, and I always have a good breadth, one of the best plots in the garden being especially set apart for the purpose. Why people will persist in setting out their Brussels Sprouts between rows of Potatoes I cannot imagine. Planted between rows of Potatoes, the young plants become so weak and attenuated that they do little good. As a set-off to this, moulding up the stems is resorted to to keep the plants erect, but when planted by themselves, at a fair distance apart, the stems stand up erect, and produce sprouts from base to summit. Moulding up the rows is a good practice in itself, but this will not compensate for other shortcomings. The seasons, again, are so short, that if the plants do not receive rational treatment from start to finish they have not time to do their work, and winter is upon us before they have fully completed their growth. Sowing in the open is of little use except in the milder parts of the country. Recognising the above, I always now take the precaution to sow in a cold frame about the third week in February. I do not believe in sowing in a box and drawing up the seedlings in heat. To get an early supply of plants I have known the seeds to be sown in the autumn, but it is a risky method, as the seedlings are very apt to bolt. Brussels Sprouts, like other Brassica crops, succeed a deal better on some soils than others. It is quite evident that

GRAVELLY SOILS do not often receive so much manure as they ought, and although on very strong soils this can be overdone, yet with the former it is often the reverse, the stems being stunted and puny, and the foliage taking on that bluish tinge so plainly caused by poverty. Close planting is also a very great evil, 3 feet on strong soils and 30 inches on light soils not being any too far apart. Good Brussels Sprouts can never be secured under the system of close planting. The tops in these cases meet almost together, if not quite; consequently, with the loss of light the lower leaves upon the approach of autumn speedily turn yellow and decay, to the detriment of the sprouts. Besides the loss of foliage through the exclusion of light, the sprouts open out and have the appearance of small Coleworts. I like to see the foliage retained until the winter is far advanced, this affording protection largely from frosts. The selections of Brussels Sprouts which are now obtainable from our best seedsmen are excellent, the plants being much smaller and compact. Large sprouts are not cared for, as herbs being too large they are strong in flavour. The Aigburth is a step in the wrong direction for private consumption, however well adapted it is for market. This type appears to be favoured by exhibitors. I find Northway Prize a capital selection, the sprout being of just the size for table use. This season I am growing Northway Prize with Veitch's Paragon and also the Aigburth, but the two former are the best. As far as hardness is concerned, coupled with a dwarf, sturdy habit, the Aigburth is quite as good, but on our strong soil the sprouts are too large and also strong in flavour. The Imported grows too tall and not sturdy enough. From a good strain the sprouts are of the right size.

A.

CELERY TRENCHES.

THERE ought to be no fixed rule as to the depth of trenches for Celery, so much depending upon the position of the garden, nature of the soil, time of planting, and the variety grown. In cold, low-lying positions, and also in all cases where the soil is of a heavy, clayey nature, deep trenches are a mistake, and that whether dug for early, midseason, or late Celery. Nor are they to be commended for shallow soils. Cultivators would appear to be under the impression that the Celery does and ought to derive its sole support from the trenches in which it is planted; whereas, the best produce, as far as quality is concerned, is had when the roots spread out well into the surrounding soil. If the latter is warm, and has been recently manured and trenched, then the roots will spread out into it freely, but when it is of a cold, sterile nature, the Celery roots will be principally confined to

the trench. In cold, sunless summers, Celery planted in deep trenches starts badly, and subsequent growth is of an unsatisfactory character, and rather than plant in trenches from 10 inches to 15 inches deep, I would prefer to put out the plants nearly or quite on the surface. Deep trenches, if frequently unsuitable for early and midseason Celery, as well as dwarf varieties generally, are still more, or always, so for the late crops. Buried deeply in saturated soil, the soft, sappy stalks and the hearts, as a matter of course, are liable to decay prematurely, even during mild winters, while should we experience severe frosts, Celery planted high and well moulded up is not so liable to be badly damaged. Nor am I a great believer in the efficacy of

SOLID MANURE when used to excess, as it very often is in Celery trenches. That this crop revels in a rich and moist root-run there is no disputing, and it must also be admitted that a deficiency of moisture at some period of the plant's growth is very often the principal cause of premature belting. By all means let the Celery have plenty of water and also liquid-manure at the roots, not merely when first put out, but more especially after the moulding-up has been partially completed, this being often the time when the plants suffer the most. Properly attended to in respect to watering, it is not so very much manure that is needed, the plants foraging for themselves right and left, and instead of the top-growth being soft and rank, the flavour also being much too strong, a solid, crisp, and sweet stick will be built up, this keeping better and proving altogether superior to that obtained with the aid of so much manure and deep trenches. What I consider deep trenches are any wholly cleared from the first deep spit of soil. The latter being distributed on each in the form of a level topped ridge certainly makes the trench appear to be much more below the level of the surrounding soil than it really is; but it is, as a rule, too deep all the same. In many cases a depth of from 6 inches to 9 inches of manure is thrown into the trench, a very little soil being brought up to the surface or mixed with this mass of manure, and this is supposed to be exactly what meets the requirements of Celery. I hold that the trenches ought not to be at any time cleared of more than half-a-spit of soil, and that a depth of 3 inches of good manure is ample for mixing with what good top soil is still left in the trench. When ready for the plants most of our trenches are filled with this mixture of soil and manure to within 10 inches of the top of the ridge, and the sides being made sloping, shrinkage is prevented, while the sunshine can reach the bottom of the trench throughout the greater part of the day. Those trenches intended for the latest crops are still more shallow, but as they are rarely 4 feet apart, there is plenty of soil between for banking up with. From the very first the plants do well, no matter how small they may be when put out. After having tried

TRENCHES OR BEDS 5 feet wide, these to hold four rows of plants, and others 18 inches or rather more in width to take two rows of plants, I long since arrived at the conclusion that in all cases where garden room is not very limited in extent and labour scarce, trenches 15 inches wide and single rows of plants are the best in the end. As far as the double rows are concerned, there is very little gain in the number of plants in a trench, especially seeing that in a single row they may well be put out not more than 3 inches apart. It is not huge "sticks" or such as gladden the heart of the exhibitor that are the best for home consumption—they are really very wasteful—but neat solid stuff, having hearts large enough for anything. In each and every case it is of the greatest importance that the trenches be got ready some time before they are wanted, as they will then be in much better condition for the reception of the plants than is the case when only dug as required. It is also most unwise to defer planting till the pricked-out plants have overgrown and spoilt each other, and having the trenches early dug does away with any excuse for not getting out the Celery at the proper time. If the plants are sturdy and moved with a good square of soil and roots, they flag only slightly in quite hot weather, and being freshened up with water occasionally, soon recommence active growth.

PREPARING FOR WINTER.

AT this season of the year it is advisable to make a note of what we may term green vegetables which will be required during the following winter and spring. Failures of the past can be guarded against, and kinds which have exceeded well must be planted in sufficient quantities to meet the supply, as it is very annoying after having only planted a small quantity of any kind for the supply to be quickly over, and to have to fall back upon others of poor merit. Many people only commence to find out what they really require when the planting season is over, or, indeed, perhaps not until the winter storms have commenced their destruction. It is very evident that crowded planting is answerable for many of the failures which do occur, and whilst summer vegetables are allowed ample room for their development, the winter kinds, and which should have the most room afforded them, are generally the worst off in this respect. High prices have often been obtained by growers for sale during the past dry months, and those who were wide-awake enough to give their produce rational culture were well repaid for their pains. Last year, when so many green vegetables were destroyed by frost, Spinaoils was about the only kind which came out unscathed, and growers who were fortunate in having good-sized breaks realised good prices. But however wholesome a vegetable Spinaoils may be, it is not everyone who cares for it, especially to use it regularly. However desirable it is to grow such a crop, other staple kinds must be forthcoming. Of the undoubted hardness of Brussels Sprouts there cannot be any question. It is without doubt the most popular and useful winter vegetable we have. To crowd such a useful and esteemed winter vegetable upon amongst rows of Potatoes is a great mistake, and I know of no other crop which so well repays for good culture. The plants after they have finished growing should stand up erect, and when this is the case, through having a due amount of room afforded them, solid sprouts from base to summit will reward the grower for his pains. This is in marked contrast to crowded-up plants, for these are invariably weak-stemmed, and the sprouts are loose instead of being solid and compact. Of the value of Kales there cannot be any doubt, and although these may stand rougher treatment, yet they will repay for liberal attention. These must be fall-grown plants by the time winter sets in, and then whatever weather—for they seem proof against all kinds—occurs, may they be relied upon in proportion to the strength of the plants, as will secondary sprouts be produced. It is in these secondary sprouts wherein lies their value, for after the main head has been cut out, sprouts which are more delicate in flavour burst out in profusion and keep on until the month of May is well advanced. The old Cottager's Kale is as useful as any, the young sprouts being very delicate in flavour and not at all bitter. The Green-courled, Road's Hearting, and Aparagus Kale may all well find a place, the last being the latest of all. It also does not appear to be very particular as regards site, as in my case it was planted in the shade of trees and has turned out well, being now (the first week of June) still good for use. Of other useful vegetables, or rather green kinds, I may instate the hardy Coleworts, so well known in the London markets, but not seen very much in private gardens. Why not, is a question, for they have a flavour, and this a very palatable one, peculiarly their own. Of their undoubted hardness there cannot be any question. By two or at the most three sowings, a succession may be obtained if a lengthened supply is needed. The first may be made in June, the second in the beginning of July, and the third with the sowing of the earliest Cabbage. Other

USEFUL VEGETABLES are Chou de Burghley and the Winstedt Cabbages. Large plantings of Savoie are not so very serviceable; certainly they are very acceptable whilst they are good, but not so hardy as the above mentioned kinds. Tom Thumb from a sowing in May is always very serviceable, and, being of a small size, the plants do not succumb so quickly to frost and damp, and after being touched with frost they are very delicious. Like the Coleworts, they may be planted a foot apart on borders (instead of early Potatoes. Preccoli I have

touched upon in a former article, and grown as there suggested serviceable crops may be secured. All the above kinds being of a hardy nature, there should certainly not be such dearths in the early spring as there have been in many gardens during the past two seasons. It may be probably on account of relying on doubtful kinds of Broccoli and also too many Savoy. I cannot give any other reason, as if the kinds I have mentioned are rationally grown, a winter supply of green vegetables should be assured. Of the value of late Celery, or, indeed, a good main supply, there cannot be any question, and if care is taken not to commence earthing too early, the stems keep sound and good throughout. When Celery decays it is through forcing on the growth, through over supplies of rank manure, and this with early earthing is the main cause of failure, too often attributed, but very erroneously, to the action of the frost. Certainly frost does play havoc, and seriously at times, but the saddle is only too often put on the wrong horse. Another useful vegetable is Celeriac. Spinach cannot be dispensed with, but the mistake is generally made in not making two sowings instead of one, or it is even better to have three, the first the latter end of July, and which will be fit, and may be gathered from early so as not to interfere with the winter crop, which should be sown about the middle of August, or even a few days later, and the third the latter end of September. Root crops I need scarcely refer to, as the value of Balsafy, Beetroot, &c., is well known. The above, it will be seen, is a fairly long list of

Early Beet.—The ordinary Egyptian or Turnip-rooted Beet has long been grown by me solely for early use, the roots becoming coarse and badly coloured before storing time arrives. The improved form, in addition to being quite as soon fit for use and better in quality, or, at any rate far more reliable as to colour, also keeps better, the roots not growing to such a great size as in the case of the old form. Last season my seed of Gilman Bill was not sown till April 20, and I commenced drawing roots about the size of tennis balls on June 24. When properly cooked these young roots prove of good colour, tender, and exceedingly flavoured.—E. W.

4002.—**Paraffin oil and water for plants.**—It is not safe to use this mixture to dip plants in, as the oil floats on the surface. It is not, however, generally known that paraffin mixes much better when first beaten up with the same amount of fresh milk, thus making it use with the syringe for easier than without this mixture. A wineglassful of paraffin, beaten up in the same quantity of milk, should be added to 4 gallons of hot water, in which 2 oz. of soft soap has been thoroughly mixed. Having added the paraffin and milk, the syringe should be brought into requisition to thoroughly mix the solution, and, in fact, used alternately between each time of syringing the plant, for the purpose of keeping the solution well mixed. Managed in this way, the paraffin will do no harm to the foliage, and it should be used thoroughly, allowing it to run down the stems, where it will collect in the "eyes," and if used as strongly as

Autumn-sown Onions.

hardy vegetables which may be produced in the open air. Do not forget to sow plenty of Onions for spring in August. A good autumn-sown variety is illustrated herewith. A.

4006.—**Tomatoes not setting.**—You have been treating them too generously, thereby causing them to make wood instead of setting their fruit. Tomatoes require an abundance of moisture and food when swelling their fruit; but until a bunch or two of fruit is formed it is easy to overdo them. Let the soil nearly dry out before watering, and then give them just enough to moisten the soil through. Give all the air possible in the day-time, and leave some on at night. This is the only way to check overluxuriance, and throw them into bearing. Pinch out the side shoots, but let the leaves that come from the stem remain.—J. C. B.

Kidney Bean Smyth's Hybrid.—This did not greatly please me when grown in pots; it proved inferior to the old Syn House, in fact. On a warm border it has done better, and last season I gathered several good dishes of it, commencing July 13. It is of erect growth, more wiry than stout, and a very heavy cropper. The pods are somewhat small, and disappointingly thin to look at, but when cooked remarkably tender and delicately flavoured. It is certainly quite distinct from any other variety I have seen, and its productiveness, coupled with the superior quality of the pods when cooked, may be sufficient to make it become popular. Note that the pods must be kept closely gathered, as they quickly become old.—I.

some reoommend might kill the plant. Many gardeners injure the tender foliage and buds irretrievably by using too strong insecticides. It should be borne in mind that it is far better to use a weak insecticide twice (at a distance of a few days apart), with clean water between, than to risk injury to the plant by the too strong or too frequent use of paraffin. But when syringing is done, it should be carried out thoroughly. There is a great difference in the way the syringe may be used; a light sprinkling from the top is of little service, and the right way to ply the syringe is in short, sharp jerks, throwing a strong jet of water both on the tops of the leaves, and more especially on their under surfaces. When syringing with vigour ordinary soap water, used once or twice a week, will keep down green-fly, with clean water between each application. It is necessary to remember that nothing should be allowed to clog the pores of the leaves for any length of time, or the health of the plant will suffer.—I. L. R.

Lychnis Haagsana.—This is a very bright flower, and one an amateur should take note of. The plant grows about 2 feet in height, and produces deep, scarlet flowers, fringed at the margin of the petals, and they vary somewhat in shade. It is a good garden plant, thriving in even none too favourable spots, but requires a little shelter to prolong and retain the colour of the bloom. The best position for this very handsome Lychnis is one that is light, well drained, and warm; but in too damp spots, frost inflicts injury. I have several fine clumps of it, and in other gardens have noticed it flowering. The robust leafage is in rich contrast to the large, showy flowers.—Y. C.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* is sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be omitted, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely, that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4015.—**Show Ferns.**—Will someone kindly tell me the name of the best six Show Ferns?—LURE TO KNOW.

4017.—**Blinds for conservatories.**—What is the best material to use for an outside blind to a large conservatory?—B.

4043.—**Hawthorn.**—Can the common Hawthorn be propagated by cuttings or, and if so will someone kindly give me all necessary instructions?—S. LEEV.

4049.—**Hardy Azaleas.**—I should be glad to have hints as to hardy Azaleas for outdoor blooming—soil, treatment, and best kinds to be selected?—INDICA.

4050.—**Shading for a greenhouse.**—I should be glad of a few recipes for greenhouse shade, including one made, I believe, with flour as a basis.—COMMON.

4051.—**Rhododendrons and Azaleas in shrubberies.**—When is the proper time to attend to these? Mine are much overgrown. Is it all right to cut them back?—T. S. R.

4052.—**A garden fence.**—I should be much obliged if anyone would kindly tell me the best kind of fence to protect my garden, which is exposed, from the east winds and frost?—LATE FROST.

4053.—**Quick growing Ivies** to plant and the best time of year to plant them, and what particular treatment would most advantage their growth?—TORMANTINE.

4054.—**Packing Peaches and Grapes.**—Will someone kindly tell me the safest and cheapest way to pack Peaches and Grapes, the same having to travel from Cornwall to London by rail?—WILLIAM MITL.

4055.—**Box-edging.**—Would anyone be so kind as to tell me the best way of putting down a Box-edging to a path? Can I take cuttings from a bush of Box, and how should these cuttings be treated, and when taken?—ALINE.

4056.—**Creeper for a cemented wall, &c.**—What creeper are there besides Ampelopsis Velutina that will cling to a cemented wall without being killed? Is it best to sow Variegated Hop and Canary Creeper in the autumn?—TORMANTINE.

4057.—**Cucumbers in a greenhouse.**—I have in my greenhouse, in pots, strong and healthy Cucumber-plants and produce a lot of fruit, but when very small, drop off. Heat 60 degs to 80 degs. Can any of your readers tell me the cause?—A. B. GREENGLADE.

4058.—**Rosa W. A. Richardson.**—I have a plant of this Rose that does nothing but grow and will not flower. It is in a very healthy condition. I planted it in the spring in a greenhouse where there was a little heat. Will anyone kindly tell me how to make it flower?—H. A. L.

4059.—**Lilies and Irises.**—I am obliged to "J. C. B." for his answer; but my mind was rather directed to growing the bulbs (Lilies and Irises) for the London auction rooms, treating the question of marketing the flowers as subsidiary. Perhaps "J. C. B." will kindly give me further advice?—AUSTRALASIAN.

4060.—**Marie Louise Violets.**—Will anyone kindly advise me how to grow Marie Louise Violets for the market with profit? What disease ought to be between the plants? Also how could I best common garden frames for the Violets? Would ordinary oil-lamps answer the purpose in winter?—S. G.

4011.—**Stachys tuberosa.**—I should be very pleased if someone will kindly give me some information regarding the culture of this vegetable? I duly planted the tubers in March; the plants are now about 3 inches or 4 inches high. I was told to earth them up like Potatoes; but I presume, considering their size, that only a slight earthing up is necessary. What size do the plants ultimately attain, and when should the roots be dug up?—A. S. M.

4061.—**Walnut tree dropping its nuts.**—I have a Walnut-tree of considerable size and age, and to all appearance very healthy, but I am sorry to find that the nuts, about half-size, are dropping in numbers from it. Can you tell me the cause of this? I am informed it has done this for several years. It is very close to a wall and is rather dry situation, and perhaps this may have some effect upon it—the soil is good and of considerable depth.—A. P. J.

4063.—**Alpine Auriculas.**—I should be glad to know what is the best time of year for mulching alpine Auriculas, and whether black mud from the bottom of a pond would be good for them? My Auriculas have not flowered yet, although they were sown nearly two years ago, but they are growing fairly well gradually. Also what is the best course to proceed with bulbs of Spanish

Iris to ensure their flowering the second year, as they seem very uncertain about coming up twice. Should I lift them when the leaves are withered?—F. RIZKA.

4061.—A plague of cockchafers.—Will someone kindly inform me the best means of getting rid of a plague of cockchafers? There are two or three trees (Horsebeams) a few yards from the house, and in the evening the Chafers swarm round these and the Virginian Creeper which covers part of the house, and thence enter by chimneys and windows into the house. We have had trees and creeper examined in the early morning, but no chafers were found on them. Would it be possible to syringe the creeper with anything which would prevent the cockchafers coming round the house?—T. H.

4062.—Treatment of a Penicillium.—I shall be grateful to be told the proper treatment of Penicillium liturcum. I planted two files but last autumn, and one is just appearing above the ground. A friend, to whose garden they have been long established, has had here over a long time. One that I had three years ago has not come up at all. Should they be planted deep or just below the ground? I think mice might be too deep. I have in my unheated greenhouse two good Prides of Peasbush Carnations. How should they be treated when the bloom is over? They have made scarcely a bit of grass.—A SUB-SCRIBER.

4063.—Ivy growing on forest trees.—I have a number of forest-trees, such as Oak, Ash, Alder, Birch, &c., on many of which Ivy has grown to a considerable extent, whilst on others it is only beginning to creep up the stems. Is its growth detrimental to all of them, and to the Ash in particular, so it seems to me to be most affected by the Ivy? In many cases it has a nice appearance, and I hesitate to cut it away from such. Gught I with those where it has but recently begun to grow out of it off? Or if it is not detrimental to the trees I might allow it to go on. Your opinion or that of any of your readers will oblige.—J. P. A.

4064.—Preparing ground for Rosss.—I wish to plant a bed of Rosss, 20 yards long by 4 yards wide, in an old neglected garden. Will someone kindly advise me as to the preparing of the ground, which is very poor? The soil is inclined to be stiff and is about 3 feet deep on clay. At present time there are strawberry plants growing and look well, but not up to the stems. I cut away from the bed a White Rose-tree in splendid bloom and covered with bloom (probably the late tea-scented one for this). The seposit is looking east and in front of my cottage. Would turning it over and mixing well with manure, or manure—or say dig out the top soil and mix up the subsoil with old mortar rubbish, and then put on the top soil—be of any service? I shall be thankful for any advice on above subject?—Novice.

4065.—A Vine question.—I wish to ask a very important question about two lots of Vines. I have three Black Hamburg and three Yellow Muscats, and both of them have plenty of fruit on them, and have looked most fruitful up to a few days ago, and now the berries shrivel up in a few minutes. It is heartrending to see it, and I only look to them next March. I was told that the berries fresh done last autumn, and now they tell me that the berries have come off for three years. I think they must be had at the roots. Would it be better to pull them out and put new ones on, or not? I must further state (from the man that was here last year) they had had spider on them, but it is out on them this, and I painted the house myself before the Vines broke. A note in this matter will be very acceptable to me and others.—A CONSTANT READER, Sals.

4066.—Management of an orchard.—I shall be glad if someone would tell me what is the best to be done with an orchard of rather more than 5 acres I have in South Gloucestershire, not far from Bath. The trees are 27 feet apart each way. They are about 6 inches in diameter, have a clear stem of about 9 feet, and there is a very great deal of unoccupied space between them. The soil so far as I have dug down, about 3 feet, consists of about two-thirds loam, rather more than one-third heavy loam, and the lower stratum osody yellow clay. The aspect is sloping due south, sheltered on the north by the rise of the hill, and on east and west by large trees. What I desire to know is what is the best way to till the unoccupied ground under, and between the trees so that I may make most of the ground than just the yearly orchard crop gets. Whether pyramid espalier fruit-trees, or bush-fruit, or vegetable, and if so, what sorts and best positions to plant?—ARRIS.

4067.—Preparing ground for planting a hedge and Papaw.—Will someone advise me how to proceed with above? If having purchased a cottage with garden and some ground, which formerly was an old bridle-path and by-road, 60 yards long by 8 yards wide, adjoining I have built a rough stone wall to the height of the ground from the bottom of ditch, and on this ground I wish to plant a hedge for about 30 yards. The ground is in the poorest condition, having run wild for years growing in abundance Ribwort, Ferns, and Blackberry bushes on the part adjoining ditch, and the road being full of Couch Grass-Seed. As the wall will be a protection from cattle, I thought to plant a Privet-hedge or some other shrub that would grow quickly. I could mix the ground or sods with manure or rotten manure to improve it. I have wired off with barbed wire and noted the other 31 yards, and one side I wished to plant a few tall-growing Poplars, which would break the south-east winds, and on the other side I wished to plant a few Rhododendrons. I could cut plenty of old sods to chop up and mix with either manure, or lime-rubbish to plant in.—NOVICE.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4071.—Pleiones (Tur).—I do not like to venture upon naming varieties from sketches, and I might make a mistake. You had better by far wait until they flower, when I should have much pleasure in naming them from a flower of each being sent.—M. B.

4072.—Oncidium cicutaria (Tur).—What are the flowers you send under the name of G. Gardnerium are

both different forms of O. curtum, a very beautiful kind. These, with O. proctotium and G. Gardnerianum, are apparently newly lifted, and they are often mistaken for each other. Each also differs much in its markings. Your two flowers appear to be a good ordinary form of O. curtum.—M. B.

4073.—Amatungula (G. Cross).—I am asked what fruit produces this preserve, which comes from South Africa? I remember some years ago having a bag of seeds given me to sow, and a box containing some preserves made from the fruit, which I at that time thought was very good. The plant is a member of the Dugheia family, and is known by the name of Arduha. Several species appear to yield a fruit, A. grandiflora being known as the Natal Plum.—J. J.

4074.—Laelia elegans (T. Johnston).—The flower you send me which bears the name is nothing but a very poor form of Cattleya Intermedia, which you can prove for yourself by examining the pollen masses, when you will find but four. You might set this plant on one side for outling flowers. I do not recommend this out of any disrespect; but I know if certain plants can be left for this purpose it saves many a fine flower one is anxious to preserve.—M. B.

4075.—Cattleya Mossii.—Jean sends me a flower of this old favourite, asking me if it is a good form. Now really, to speak (or write) truthfully, I must say this about the worst form of the plant which I have ever seen, and I have seen many. I would advise Jean to try the plant on the fire and not to be troubled with such a bad variety any longer. A fair variety does not require a white more care, and it gives infinitely more pleasure. When you buy ask if the plant has flowered, and what sort of a variety it is; you then have a guarantee.—M. B.

4076.—Oncidium Lepoldianum.—J. C. B. E. asks me what this kind is like? Well, now this is one of the few Orchids which are so cultivated of which I have no knowledge, and, therefore, I cannot enlighten my enquirer's friend. I only know it is a plant that has been introduced by M. Ledoer, of Brussels, who has dedicated it to the King of the Belgians; therefore, I should imagine it to be a good thing. Perhaps some of my readers have the plant either in flower or just coming into bloom, and if so a flower would be highly appreciated by—MATT. STAMER.

4077.—Laelia Picheriana (Chas. West).—You have evidently been misinformed respecting this plant. It is not a cross between Laelia crispata and Laelia elegans; the last-named plant is quite innocent of any complicity in the cross; but I, in the address made by my good old friend, Mr. Dunlop, between L. crispata and L. Picheriana, and it is dedicated to Mr. Picher, who had charge of Mr. Rucker's Orchids to the last. I think, however, that the plant is very rare. You certainly would not pick it up for a few shillings. A plant having this name you may have got, but it certainly is not Laelia Picheriana.—M. B.

4078.—Oncidium essale (C. Jessop).—This is the name of the flower you send, and in spite of what you say I cannot help ascertaining that it is a very beautiful species. It used to be very rare, and now, although not commonly seen, it has yet been imported in some numbers. Its flowers are of considerable size, in those blooms no just under 3 inches across; the sepals and petals are bright esnary-yellow, with bright brown dots, and these give rise to the esposito name. The lip being of the same colour, dotted with reddish-brown. It first flowered in this country upwards of forty years ago.—M. B.

4079.—Lagerstromia.—G. Robinson asks if these plants are really beautiful plants. I can only assure him that they cannot have heard their praises overrated, for they certainly may be said to be amongst the most lovely flowering plants that I know. They belong to the family of Loose-strifes, and are species of L. Indica; they thrive and flower well in the open border in the south-western counties. They should be grown in a mixture of peat and loam, made esody. They should be potted firmly and watered freely. In the winter season they should be kept by keeping them feily dry, but the wood should not be allowed to shrivel.—J. J.

4080.—Cattleya Intermedia (Tur).—The flower sent represents an excellent variety of this pretty plant, and it is one which I am very fond of. If you cannot keep it moist enough on the back, build a little Spagnum upon it. I do not see why you should be compelled to take it off the wood. If you do not do it, but endeavour to hang as I told you, it should be alive upon it. You will have no trouble in keeping it supplied with the necessary moisture, but then you will have the advantage of growing it in its natural condition. If you wish to pot it, in the spring is the best time to do so, taking advantage of the time before it starts into growth of either root or shoot.—M. B.

4081.—The Papaw-tree (C. Jenkins).—This, my enquirer says, is said to be a native of the East Indies, to which I must differ from him, for I think it is now admitted to be a native of South America. But the Papaw (Carina papaya) is cultivated in most tropical countries, so that its exact native place is somewhat obscure. It is said to have the property of making fresh killed meat quickly tender, simply by hanging it up amongst the leaves, and the fruit gives a mild preservative and renders their flesh tender. But it is the ladies appreciate it the most, for they use it to juice for the removal of freckles from the face.—J. J.

4082.—Sophronite grandiflora (Tur).—Yes, I have noticed all the three forms that you sketch, and I hope you will not be disappointed with No. 3; but this one I have observed produces small and poor flowers; but No. 2 of your Illustrations I have seen produce very fine flowers.—Indeed, the finest form of this species which has ever been seen, I think, was from a bulb in this description. The No. 1 I have never seen to yield but poor blooms. The price paid for it, however, was by no means excessive, but the sale prices for the others were simply absurd. You do not deserve to get a good variety from other, and this is my candid opinion. I am glad you are making the home of the late Captain Maryatt famous. His mother used to have a fine collection of plants there in her day; but perhaps you do not remember it?—M. B.

4083.—The Turk's Cap Cactus, Misocactus (Columbus) (Henry Mansell).—These, I should think, are the plants which you have recently received from the West Indies. I have often received them as large as you

name, and like yourself, failed to save even a single one of them. Long before twelve months was over the place that knew them once knew them no more for ever, because they decayed just in the same manner you describe yours to be doing. This set me to thinking—what could be the cause of it? And I come to the conclusion that it was quite a mistake these large plants, which in all probability were near their full size, and these, perhaps, in consequence of their size, received more damage to the transit than would be the case with smaller plants. So I got a box of plants 6 inches and 9 inches high, sent home, and these came home under the esposito's charge, and the plants came to hand in sound condition. They were potted in old mortar rubbish and a little loam, treated like other Cacti from warm regions, and they grew and increased to size beautifully.—J. J.

4084.—Jalantinas.—C. R. C. says his plants of these are now growing well, and he thinks they would like a shift now. Might he give it them? They are to large 60's cow, three bulbs in a pot, and they are now about half grown. Yes, certainly, shift them into a small 3 1/2", using peat-fibre and Sphagnum Moss, with a little sharp sand mixed with it. You may keep them in the warmth of the stove, with a nice moist heat, and do not allow them to want for water to their roots during the growing season. No, I should not advise you to use mortar of any sort to them. I do not like it. I have seen many collections to which liquid-manne had been given dis quite out after a few years. They became attacked by a black spot which affected the bulbs first; afterwards increased with the growth, and eventually spread over the young bulbs, finished them off and causing death and destruction to the whole lot. If you have not begun to give your plants any liquid, do not give them any, and if you have given them some, I advise you to stop it at once.—M. B.

4085.—Blight on a Pear-tree (The Rev. H. I. Rawlinson and F. Barchard).—Your Pear-trees are attacked by the grubs of the Pear Saw-fly (Sals adria esalis), which eat the surfaces only of the leaves, the veins remaining untouched. When these grubs are fully fed, they climb their skins, and having got rid of the dark brown, scaly covering, appear as bright yellow grubs. They now leave their mid quarters on the leaves, and reaching the ground, bury themselves and become phrysalides within a dark papry cocoon, two inches or so below the surface. In this condition they pass the winter, the Saw-flies emerging to the spring. If everyone in a certain district would remove the earth in the winter from trees which have been attacked to the depth of 3 inches, not harm or bury it, this pest might be almost stamped out. As regards means of destroying the grubs when on the trees, dusting the leaves with well powdered quick-lime, or gas-lime, or esyloging with 7 lb. of soft soap, or extract from 8 lb. of Quassia-shells, or 2 lb. of Tobacco, and 100 gallons of water, are the best.—G. S. S.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Miltbush, es. Kidder.—Festuca paniculata;—Subscrber.—Cattleya Mossii, good in size, but deficient in colour.—C. Hebbel.—1, Phlogoth norooopis; 2, Valeriana dioica; 3, Parisotia officinalis; 4, Potentilla reptans.—C. Dyanond.—1, Epilobium radicans; 2, Cattleya Forbesi; 3, Odontoglossum luteo-purpureum.—G. Ellis.—1, Lycaste Harrisonii; 2, Cattleya Mossii; 3, Laelia purpurata; 4, Oncidium festucosum; 5, Vanda tricolor insigne.—C. Bell.—1, Athyrium Filix-femina glomerata; 2, Lactuca Filix-mas gracilioris; 3, Polypodium angulare divilatum; 4, Scopolium tuberosum; 5, Lactuca Filix-femina; 6, Athyrium Filix-femina serotianum.—J. Marchant.—1, Cattleya Steudeliana; 2, Laelia Russelliana; 3, Epilobium violaceum majus; 4, Odontoglossum luteo-purpureum radicum.—G. Berrie.—1, Euphorbia Helioscopia; 2, Polypodium monspeliense; 3, Allium triquetrum; 4, Senecio Jacobina.—Charles Watson.—Venus Looking-glass (Specularia speculum).—Mrs. Prince.—Speculons not numbered, so we cannot name them.—A. M. C.—Thlasium adanifolium.—Antoinette.—We cannot name garden varieties of it, but we can name some of them.—Andrews.—Daisy.—Impossible to name from such dried-up specimens.—J. Paley.—1, Acer Negundo variegatum; 2, Weigela rosea; 3, Yucca Traversi (probably). Send again.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot take time to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Anxious.—Yes, an Index to GARDENING is published annually, price 1s., and can be obtained from this office.—Andrews.—Baz.—Mr. A. Piper, High street, Uckfield, Sussex.

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This journal is published in weekly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price, 1s. 6d.; post free, 1s. 8d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Farm and Home" Monthly Parts.—This journal is published in weekly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 6d.; post free, 6d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with full details of their arrangement, culture, &c. With a new and improved Edition. Price 1s.; post free, 1s. 2d.

CHINA ASTERS.

It not infrequently happens that these Asters, ere they can become well established, are badly infested with aphid. The leaves then become stunted, and the side shoots, which at once break up prematurely, are never capped with fine blooms. Generally this season so far, and in spite of the earlier drought, Asters are very good, and we may look for a full bloom in due course. It is difficult when Asters become blighted to dislodge the insects, because they usually favour the undersides of the leaves. Perhaps the best plan is to water liberally with soapy liquid in such a way that much of the water will splash up under the leafage and render it obnoxious to the aphid. If this be done at night and a good dressing of soot added it will prove very efficacious. The soot should, however, be partially washed off by sprinkling with clean water next morning ere the hot sun scorches the foliage; those waterings thus serve a double purpose, as whilst checking the fly they also help to manure and stimulate the plants, so that very soon new roots are formed. Stout growth ensues, and a wonderful change is presented. It is not at all satisfactory to sow Asters where they are to bloom, not only because owing to our late, cold springs germination must be both late and uneven, but also, unless transplanted, too thick to be of any use. Aster seed, if of a good strain, is also too expensive to be sown in any other fashion; hence the rule invariably followed of raising the seedling plants in boxes or pans or in frames, of course, under glass, is at once the wisest and most economical. I can remember the time when in a large nursery in the south of England it was the rule to raise the tender annuals on long hotbeds covered with soil, and which were protected from the weather by hoops of Ash or Hazel, and covered with mats. That was the practice some 50 years ago when glass was not so cheap and frames not so plentiful as now. In the area of a frame some 8 feet by 6 feet it is possible either in shallow boxes or by sowing the seed in shallow drills in a soil bed, that is, near to the glass, to raise plenty of stout plants. There is, perhaps, no better way, because plenty of air can be afforded as desired.

DRILLS may be seven inches apart, and the seed should not be sown thickly, as if such be the case the end of the grower will be largely defeated by producing an excessive quantity of weak plants rather than fewer stout sturdy plants. The same rule applies to raising Asters in pans or boxes. Once the plants are 3 inches in height they need immediate transplanting into other frames or where they can have shelter from cold winds and frosts. The soil should be specially prepared with plenty of chert manure or leaf soil to promote abundant root growth, and some shading can be given if required until the plants have become established. Even in preparing for this first transplanting it is poor policy to pull the plants bodily from the seed-bed or pans to the manifest injury of the roots. The best course, as in all similar cases of seedling plants, is to employ a small hand

fork to assist the roots coming up freely and without injury. When so much trouble is taken the plants are far less likely to be attacked with aphid than when roughly used. If then dibbled out carefully at some 3 inches apart all over the frame in prepared ground, they will soon form strong plants. If seed be sown early in April, even in a cold frame, for bottom-heat is rarely needed for good Aster seed, the seedlings will be ready to dibble out in five weeks, and again may be finally transplanted where to bloom early in June, being then very strong, sturdy, and well-rooted. Each plant lifted with a trowel will have a good clump of roots and soil attached, and planted also with a trowel will, if well watered—that is, if the weather be dry—hardly suffer at all, and, making good growth all the summer, carry in the early autumn fine heads of flowers. In the case of growers of the seeds of plants, either for market sale or seed-production, it is the rule to transplant seed only, that is, from the seed-boxes or frames direct into the open ground. Where that course is perforce followed, it is best to sow seed thinly in shallow boxes, getting it to germinate quickly in frames; then as soon as the plants are well in rough leaf, leaving them fully exposed to light and air except at night, so that the plants in no way become drawn and are rendered hard and wiry. These plants have to be put out when comparatively small, and, of course, presenting an easy prey to slugs; therefore, the harder the stems before being exposed to that danger the less likely are they to be attacked. If, however, after being well watered in, a dusting of soot be given some two or three times during a fortnight, very few indeed will fall a prey either to slugs or aphid. Once well established in the open ground, Asters can take good care of themselves and in due time give a superb show of bloom. Truly beautiful indeed are the colours to be found in the various sections. We may, if we want variety, have a dozen diverse sections, and a dozen of diverse colours or markings in each. Growers for ordinary garden decoration like plenty of variety; growers for market like a few striking colours, such as white, blue, purple, carmine, red, and crimson. Of this last hue, some sections give most brilliant shades, and masses of them growing in the broad sunlight are indeed beautiful. The crown or edged flowers are pretty, but not so constant or, on the whole, so useful as are the self flowers. Striped flowers also are more or less pretty, the white and blue and red and white of the Victoria and Peony-flowered sections perhaps being the most effective. Those two sections give the best flowers for exhibition, the dwarf Chrysanthemum, dwarf Victoria, and the Bouquet the best for market work, lifting the plants and clumping them into pots for sale. The Mignon is the best section for cutting from. Those who like quilled Asters will find them easy to grow, but the flat-petalled forms are on the whole cheaper and more effective. A.

Marigold Orange King—A fine variety of the common Marigold is named Orange King. The flower is of very large size, the boldest I have ever seen, and the colour is intense orange.

It is a bright and handsome variety, and although very large is in no way excessively coarse, as many high things. The Marigolds are so easily grown that the variety Orange King may be tried. In a group its large handsome flowers tell well.—V. O.

FLOWERS FOR DUSTY GARDENS.

ONLY those who are fond of flowers and are similarly situated can understand the difficulties and annoyances that have to be endured by those who have gardens in front of their houses close to a dusty road or which there is much vehicular traffic. Three years ago my advice was sought in this matter, since which I have been experimenting with a view to find out what are the most suitable flowers to grow in such gardens, and I find that these with a pendant habit give the most satisfaction. Fuchsia, I should say, head the list, and next to these the drooping forms of the Tuberosa Begonia. These two subjects may be called almost dust-proof, as not much of it finds its way into the centre of the flowers, and, what is equally so important, the dust is more easily washed off without injuring the blossoms. Anemions do fairly well, and the same may be said of the Dwarf Nasturtium. Amongst hardy flowers the old-fashioned Columbine, Pentstemon, and Antirrhinum are fairly satisfactory. I may also include the Tufted Pansies, not because the dust does not lodge on the foliage and flowers, but because the blossoms are not injured when it is washed off, which it can be through a fine rose watering-pot. Plants with narrow leaves and small flowers are certainly the most suitable for dusty gardens. Roses are, I think, the most unsatisfactory of any, especially those with cup-shaped blooms, and double Pelargoniums do better than single ones. I should mention Sweet Peas as being serviceable, because the dust can be removed by gentle syringing with water without damaging the flowers. Taken altogether I do not know of a garden in any other position so unsatisfactory as those to which I refer. I fancy there must be many readers of GARDENING who could help each other by sending the names to the Editor of any flowers they have found to be suitable for such gardens as I have alluded to.

J. C. C.

SHADING PLANTS DURING DROUGHT.

THE prolonged drought is beginning to tell its tale with all sorts of plants, although some, by their stronger or deeper-rooting nature, withstand it better than others; but all will need extra care to guard against injury, or the probability is that many valuable plants will be lost, and others greatly crippled. Amongst those that show signs of distress with me are the Primrose, Polyanthus, Daleis, and other spring-flowering plants which have completed their growth and are about to rest for awhile; but it must be remembered that they are not able to defy drought like the Cactus or Agaves, and if allowed to go fully exposed to the burning sun and acid drought will probably succumb, and I find that slight shading helps them greatly—in fact, far more than copious supplies of water,

for if a covering of long Grass is shaken over the beds before the soil gets very dry, one good soaking will last for a long time. Violets are moisture-loving plants, but as they are making their growth now, they cannot be shaded in the same way; but I always plant between rows of fruit-trees, where they get partial shade. They must be kept well watered at the roots, and a good dash with the garden-engine in the evening will greatly help to keep red-spider at bay. Plants in pots, especially Azaleas, Camellias, &c., when placed out-of-doors, need shade from the direct rays of the sun. A good place is where they get shade from 10 a.m. to 3 p.m., as the sun's rays will do them good at other portions of the day; but in such seasons as the present, when we are getting a double share of sunshine, great care is needed to guard such plants against full exposure, as, however good sunshine may be for many plants, there are many that cannot withstand its full force without injury.

J. G. H.

GARDEN WORK.

Conservatory.

Many plants which have been brought on in the stove will now do in the conservatory. Gloxinias will make charming groups mixed with Maidenhair and other light-foliated Ferns. Specimen Bougainvilleas may have prominent positions, and Caladiums will last in beauty of leafage a long time if kept a little close and shady. Groups of Calceolias, mixed with Ferns, may also be employed to give variety. Lilies, a variety and others, now throwing up flower-stems should occupy a light position to prevent being drawn up weakly. Insects have a preference for the flowers of the plants which are now in flower, and must be kept down by dusting with Tobacco-powder or by washing or dipping insecticides sufficiently strong to kill the insects, but not strong enough to injure the tender growth. Winter-flowering plants growing in the border, such as Abutilons, may be cut back to get a new growth for winter flowering. Should mildew appear on the Tea or Nettle Rose planted out, dust the first affected spots with sulphur; but, as a rule, mildew will not give much trouble under glass at this season unless the Rose roots are too dry, and this should be soon to. Indeed, all specimen plants growing in the border will require more than the usual supply of moisture in the present season. The last of the hard-wooded plants should have their growth sufficiently verdured to bear exposing outside if the removal is well-timed. Pick a dull day, if possible, to take them outside, or else stand them in a shady spot for a time till the foliage hardens a bit. Specimen Plumbagos, both the lilac and white, will be very useful now, though the flowers are hardly lasting enough for cutting. Both kinds are rather a pretty plant for blooming in summer. It belongs to the second class of old-fashioned plants. The Brugmansias are striking plants, and either planted out or in large pots will require a good deal of attention in the shape of water and liquid manure. These are useful plants when grown in tubs for standing outside in association with Agapanthus, Orange, Myrtles, &c. Cut down Pelargoniums and put in the outtings. They will strike anywhere new. Surplus Fuchsias may be planted out. Outside plants are the best to get cuttings from in autumn for early blooming in small pots. Zonal Pelargoniums for the conservatory should have their final shift. If over-potted the plants will get the growth ripened sufficiently before the short days come. A good specimen may be had large enough for winter bloom in a 6-inch pot, and many of ours will be in 5-inch pots, as these pots are more suitable for placing on the shelves near the glass.

Stove.

The various varieties of tropical Asparagus are charming things to plant out in the stove wherever there is room for freedom of growth—the ferns are so nice for cutting for table decoration and other purposes where elegant greenery is required. Young plants should be grown in pots, shifted into those of larger size as more root-space is required. They are easily raised from good seeds, but seeds are scarce. Propagation by division is rather a slow process when one only has a few plants to deal with. It will be better if those foliage plants, such as Crotons and Dracomas, which require a strong light to colour the foliage, could be moved to a small house where less shade is used. The syringe must be used freely to keep down trips and other insects, but soft water alone should be used. It is well to have a deposit of lime on the foliage that would spell the effectiveness of the plants for a long time. A little more ventilation may be given to the stove during the next two months or so, and a little less moisture used inside. Ties will tend to the maturing of growth, and fit everything to pass through their third days of winter. Orchids which have completed their growth will be all the better for a little more air and less moisture. Achimenes and Gloxinias may be moved to the conservatory with any other plant in bloom which can be spared.

Ferns under Glass.

If the fronds are required for cutting give as much light as is consistent with plenty of green colour in the fronds. If the glass is unshaded, or not shaded sufficiently, the fronds will be of too dark a green. We want to be the happy mean of producing dark-green fronds with sufficient substance to remain firm in a cut state. Young plants which are in 6" or 8 1/2" pots, and which are moved at once into 6-inch, will be useful for winter decoration. Ferns of all sizes are requiring the room and table decoration nowadays. Even plants in thumb-pots,

if healthy and well grown, can be usefully employed. There is an endless variety in Ferns, but the number that will bear the rough usage of the decorator is limited. If fertile fronds, with the spores sowing a dark colour, are gathered and placed on white paper in a cool room, the spores will fall as they ripen, and may be sown immediately.

Hard-wooded Plants in the Open-air.

These should be arranged on beds of coal-ashes, with paths between, at suitable intervals to give free access for the purpose of watering &c. Camellias will be better in the shade, as their hard, shining leaves are so easily injured by hot sunshine, or otherwise damaged. It is not customary to pot hard-wooded plants so late as this, but if there are any plants in a pot-bound condition, or the principle of choosing the least of two evils, I should repeat now, pressing the soil in with the pointing-stick as freely as possible. Plants in the open-air often require more water than they do under glass, especially at first, and constant vigilance must be used that nothing suffers for want of water. Every pot must be tapped with the knuckles to insure its proper condition being ascertained. In very hot weather it is beneficial to sprinkle the surface of the ash-bed every evening.

Frames.

These will chiefly be occupied now with young stuff coming on from the production of winter bloom. A little air will be useful now to harden and check luxuriant growth. Seedling Begonias which have been raised this year may be planted out. The early raised plants will be in blossom, and even the latest plants will make mere growth if planted out in a bed of good soil than in pots. These small tubers will, of course, be lifted and packed away in boxes of sand for the winter. Primulas, Cyclamens, and Cinerarias are growing freely new, and will require shifting into 6-inch pots.

Window Gardening.

Among flowering plants will be Fuchsias, Hydrangeas, Double Petunias, Musk, Tuberosus Begonias, and Zonal Geraniums. All these may be improved by weak stimulants. The well supported plants look sounder, better, and happier than these which are given the help beyond what is contained in the soil and water, as obtained in a state of Nature. Do not keep any plants in the room which are not effective, as they will recover tone sooner outside. Cuttings will strike even in a shady window, or even outside, if placed in a shady position.

Outdoor Garden.

Now that rain has fallen in sufficient quantities to make some impression on the thirsty ground, budding of Roses and layering of Carnations must be no longer delayed. Unless Carnations can be layered as early as possible, the strong plants ready to pull out early in October, they do not get that grip of the soil which will enable them to resist successfully the lifting power of the frosts of early winter. Unless I could get Carnations planted in the beds early in October, I should pot them and keep in a cool frame or cool house all winter, and plant out in March. I am convinced that this is better than late autumn or winter planting. There is yet time to sow annuals for spring blooming. Most of the hardiest annuals may be sown, if desired, including Iceland and other Peppars; but for bedding purposes something compact in growth is required, and in this respect Silene composita, Bapenaria caerulea, Limnethes Douglasii, Myosotis denticiflora, and Clarkia poliochilla alba, are reliable. Prick out Wallflowers and any other biennials or perennials large enough to handle. There is always time to do among Dahlias, Hollyhocks, Phloxes, and other late-growing things. Delphiniums have been wonderfully good, and have stood the drought well. Asters are also good dry weather plants where well established and fast enough in the ground. The dry warmth of the season seems to have suited the Toll-trees; several fine specimens which have come under my notice lately have been beautifully in blossom quite a month earlier than usual. The Tulip-tree should have a place on every lawn, where there is room to plant a tree that will grow 70 feet high. Bedding plants are growing freely now, and will used a good deal of attention.

Fruit Garden.

The land intended for Strawberries should be made as good as it can be by deep culture and fairly liberal manuring. It is a good plan to trench up a piece of land in winter for an early start in the spring. The Potatoes are not likely to be diseased; and when the Potatoes are lifted give a dressing of soot and superphosphate; fork it in lightly, and plant the Strawberries. Here the plants as strong as possible, and take a good crop first year. This is quite feasible if the early conners are secured, and either layered in pots or in mounds of rich soil placed among the plants for the purpose. Red-spider will be busy, both under glass and also outside, where the water supply has been too limited. Watering is heavy work, but it is such a pleasure to be able to point to clean, healthy, well-developed trees in a season like the present, and healthy nourished fruit-trees and plants are a standing reproach to those in charge. This is what makes a good man feel so uncomfortable when his hands are tied for want of means. If the young shoots or the fruits on Peach-trees still seem crowded, remove the surplus at once. It is the worst possible treatment to leave too many; this has ruined more trees than either frost or insects. Young trees on walls making very strong growth should be stopped to reduce eyes to break level down, and the best of these lateral shoots may be laid in. In strong growths which young trees often produce grow out their full length unstoppped, as they will have to be shortened back considerably to get the bottom furnished. Leave a little air on vinerias and Peach-bowes all night now.

Vegetable Garden.

There are some things which must be sown or planted, on matter what may be the condition of the weather. If sufficient Cabbages are not sown, get the seeds in as once, having first well soaked the bed with water the night previous. The only kinds suitable for sowing now are the earliest of which a good selected stock of Ellam's Early is the best. Endive, both the green curled and the Bolognese, will come all right now. Every bit of lettuce that should be sown as soon after the preceding sowing as

cleared off as possible. There are many things which ought to be sown or planted within the next month. Sow Brown Coo Lettuce. Spinach of the prickly variety so now; a few of the plants may bolt, but for the most part, if the seed is in good heart, as regards depth and mairing the crop will stand. Lift early Potatoes, and prepare the land for other crops, such as Turnips, Leeks, Cauliflowers, &c. Get out a good patch of Veitch's Self-protecting Autumn Broccoli; it will prove invaluable towards Christmas. See that the plants have a fair number of strong fibrous roots to come on for succession. Trim off the leaves from Cabbage stems where the Cabbages have been out; several good hearts will spring from the stems. The rows of early White or Red Celery may be blanched by wrapping folds of paper round them, first tying up the leaves. Any kind of paper will do, so that the light is excluded. Watering can be continued after the paper is on. Give ample support to Tomatoes, both on the side and under glass. Stop all leaders on the outside plants by the end of the month.

E. HOSKAY.

Work in the Town Garden.

If the showery weather we have been having for the last two or three days continues, things will grow more in a week than they did in a month previously. No amount of watering has the same effect as the natural moisture that falls from the clouds, and it is curious to notice how quickly even plants under glass respond to the effects of a rainy day or two at this season, for no matter how freely watered they are, they are always a little behind those on the outside air is heavily charged with moisture. In the outdoor garden stage, of which I have said little or nothing for months past, will soon be putting in an appearance again, and steps must be taken to check their ravages in good time. They are particularly fond of the young shoots of Dahlias, so that every plant must be surrounded by a good ring of ashes and soot; sawdust is also a capital thing, and as long as it remains in anything like a loose condition they cannot possibly crawl over it. Pelonias, Marigolds, and some few others they are also very partial to, and these must receive particular care. To destroy, or rather keep down, the multitudes of small fry that are found in some gardens, the best way is to get out after dusk on a moist evening, with a muslin or other open-textured bag full of quicklime in a finely-powdered condition, and a stick, and by a judicious use of the latter give the whole of the beds and borders a light dusting. This will effectually settle all that it touches, and do no harm to the plants. This is the right kind of weather to plant out seedling or small Begonias; with very little care they will get hold almost directly, and grow right away. Chinesa Begonia in May should be planted out at once; those who do not want these charming and ever-lasting flowers until the autumn will find this plan an excellent one, and far less troublesome than the usual method of sowing under glass. Carpet-bedding should be finished off without delay; in many places the bedding-out has been delayed long beyond the usual time on account of the scarcity of water, and the period of extreme drought and tropical sunshine we have lately passed through (I trust), has been very trying to small plants of a tender description only just put out. Best layering of Carnations as soon as possible, the earlier they are got to work the better, and the "Grass" is usually forward, and where the plants have been well attended to, strong also. Prick off seedlings in stove beds as soon as they can be handled; there is nothing to equal seedlings for flower production. A light sprinkling of nitrate of soda on a burnt-up lawn will quickly restore it to a healthy colour new.

B. O. I.

THE COMING WEEK'S WORK.

Extracts from a garden diary from July 8th to July 15th.

The budding of Roses and layering of Carnations has taken up a good deal of time during the week. The flowers of both of these classes of plants are so beautiful for every purpose for which flowers are required in a cut state, and the plants are so popular, that no one is likely to be too anxious to have them as soon as possible on the dwarf Brier, some on the seedling Brier, and others on the stocks raised from outtings. Tus chief thing that is impressed on my mind, after many years' experience, is that one cares to dwell overmuch upon, is the necessity for dressing and manuring the soil for Roses of all kinds. And I have had more ups and downs in my struggles in growing Carnations than with Roses; and I envy those who have nothing to do but potter about and watch these things grow and blossom. Wireworms are a terrible pest in a garden; they can be got rid of in time, but it takes years to clear them out. Thorough cultivation is the best remedy for wireworms. In all the land I have seen turned up, I have never found a dead wireworm, and their bodies, if they died through the application of lime, soot, &c., which has been scattered over them, would be found sometimes. If one could turn in a lot of chickens every time the spade was used their sharp eyes would detect a good many of them. But in the struggle with insect pests man will, if he perseveres, conquer. Sowed Cabbages of the earliest kind. I have seeds sown earlier, but I generally sow two sowings. The best sowing not injured by frosts in the seed-bed till spring, and Cabbage-plants are always useful, both to plant out, and give away to neighbours; but the old-fashioned idea of giving away surplus garden stuff is now expanded. Even the squire and his lordship sell garden produce. We shall soon all be shopkeepers or market gardeners; the only difficulty will be, in face of the increasing foreign competition, to find customers. Nailed in young wood on Peach wall. Early kinds of peaches are showing signs of ripening; turned back the leaves which fall over the fruit, and some of the leaves have been pinched; fruit cannot colour unless exposed to the light. Peaches on walls have been heavily watered over the mulch of manure which had been previously placed over the soil containing the roots. This mulch will be raked off when the Peaches are gathered to let the solar warmth into the border, and to help in the ripening of the wood. Gave another top-dressing of Patent Silicate Measure to borders of late vinery. Tomatoes in unpeeped houses are ripening in large quantities now. Ham Green Favourite nearly as much earlier than the old red, and the round kind which ripen well, though the crop does not

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

look so heavy on the plants. It pays to mulch Tomatoes with manure; it saves watering, and the roots derive much support from it, and the blossoms also. I always find it necessary to begin this feeding when the first trace of blossom has set and the fruit swelling. If this support is not given in time the upper blossoms fail. I do not believe in syringing Tomatoes, as a rule, but in hot, parching weather I often turn the hose on just to give the plants a light, refreshing spray; it helps the setting. Potted on Cinerarias, Primulas, and Cyclamens. Potted off seedlings of Dracaena and Aralias. Put in cuttings of Hydrangeas.

FERNS.

NOTES ON FERNS.

CONSERVATORY FERNS.—Under this head I would more particularly direct attention to those kinds which will thrive in a minimum temperature of 40 degs. or thereabouts during the autumn and winter season. In most conservatories and show-houses there is room for

are grouped together. When the supply of flowers is at all short, a good stock of Ferns is of great assistance in conjunction with other plants of fine foliage. It pays therefore to grow some few kinds in goodly numbers, according to the case in point. Of these mention should now be made more particularly of the hardier of the Aspleniums, most of which can be easily increased at this or any time of the year by the small hulihs forming on the fronds. About now these are in a good condition for removal. This may be done by taking small pieces of the old fronds with several young ones forming and pegging down upon sandy soil, or it may be effected by taking each young plant separately and then carefully embedding it into the fresh soil. For this purpose shallow pans will be found the best, as no great depth of soil is really required. If taken now these hulihs would form nice y ung plants fit for 2½-inch

CYRTOMIUM FALCATUM is another fine enduring Fern for the cool-house. The greenhouse varieties of Lastreas (Aspidiums) should also be noted, particularly L. lepida, L. Sieboldi, and L. Standishi. Several of the Pteris family are decided acquisitions. Of the taller growing kinds P. tremula is one of the best of all Ferns, suitable both for associating with other kinds as well as for grouping with flowering plants. The various forms of Pteris cretica and P. serrulata are also excellent Ferns for many purposes, particularly P. cretica nobilis and P. serrulata cristata major; P. nimbrosa, although of more vigorous growth than P. cretica, is equally useful. Woodwardia radicans is not half enough grown; when seen fully developed it is a noble plant. The foregoing list does not include nearly all that are well worth more extended cultivation. I feel fully persuaded that not nearly enough is made of Ferns on the whole for the purposes indicated at the commencement of this article. If looked after with ordinary care they are always to hand, and are so useful when rearranging is being seen to, filling in many places when flowering plants would not be nearly so suitable. Scale may in some cases be found troublesome, but with attention bestowed in nothing more than the average way it is easily kept under.

HARDY FERNS FOR DECORATION.—One often hears the complaint of such an amount of plants being required for indoor decoration, with the results consequent thereto of the plants being permanently injured, or so much crippled, as to require careful treatment for some time to come. Now if hardier plants were more used, as those now under notice, a deal of future trouble and annoyance would be saved. They are well suited for the purpose in many ways, and may be chosen in considerable quantities as to variety to suit given cases. These are those which always look best when placed upon the floor or sufficiently low to be looked down upon. For instance, the Polypodiums, the Lastreas, the Onundas, and the larger forms of the Scolopendrium all look well when stood upon the floor. For vases and baskets there is also a good selection from amongst the following: Adiantum Capillus-Veneris and A. pedatum, Allosorus crispus, the Aspleniums and Athyrium, Cyatopteris bulbifera and C. fragilis, with the crested forms of Scolopendrium vulgare. A few of these latter may require for greater safety the protection of a cold frame in winter, otherwise when they grow shabby in the autumn all that will be required is to plunge them in a bed of ashes, quite covering the pots. For this purpose a north aspect against a wall would be as suitable as any place that could be chosen. Here they could remain until the first signs of growth are apparent in the spring when any needful attention in the way of potting or top-dressing could be seen to. It should be borne in mind that large pots are not in any case required, whilst if not so much over-watered during the summer as to cause injury to the roots, they would remain for some few years in the same pots. Loam, not too heavy, with leaf soil and road scrapings is a good mixture for them, potting being done pretty firmly. One great advantage in making use of these hardy Ferns is that they never need occupy any house room during the winter, neither, indeed, do they require it at other times, although probably they might be found useful even in conservatories during the summer months. These hints on hardy Ferns and a few of their uses in pots are made now so that those readers who during their country rambles may come across the British kinds can collect them for potting up this autumn. If not obtainable in this way, they can be easily purchased at a cheap rate, but in any case it is best at the start to repot in the autumn rather than the spring. The hardy kinds (not British) are catalogued, and the best sorts even can be purchased at cheap rates in small pots; this it would be desirable to do next month whilst they are still in good condition. F.

A Maiden hair Fern (Adiantum) in a basket.

small or medium-sized plants of this character. There are frequently in such houses places where it would not be possible to keep flowering plants for any length of time with even a moderate amount of success, but where Ferns that are of an enduring character may be kept for months together. By growing a goodly number for such purposes there is a considerable saving in the quantity of flowering plants required to completely furnish a house, whilst the effect is in nearly every case considerably enhanced by the addition of the green foliage of the Ferns in contrast to or the subduing of the various colours of the flowers, particularly when these are employed in a liberal manner. In the case of tall-growing flowering plants, as Lilliums of various kinds, the Callias, the Tuberoses, and the Francoas, these Ferns constitute a most desirable and effective groundwork, in this manner looking much better than when many flowering plants

pots by the end of September, and 3-inch pots the following spring. Asplenium hulhiferum, A. flaccidum, and A. diversifolium are three of the most useful as well as being those of the easiest to propagate for decoration by the aforesaid method. Asplenium lucidum is best raised from seed; this is one of the hardiest of all greenhouse kinds, somewhat liable to attack by thrips, but these are easily overcome by the usual methods employed. Seedling plants of Dicksonia antarctica are extremely useful whilst in a small state, with the knowledge that the most promising will eventually make good specimens with ordinary care. This Fern, like the Aspleniums, will withstand the sun's rays remarkably well. Of the Adiantums note should be made of A. pubescens, a very hardy kind; A. venustum, of Maiden-hair-like growth; A. colpodes, A. decorum and A. Williamsii, also partaking of the same character, are all good enduring kinds

4046.—**Show Ferns.**—If exotic Ferns are intended, the best genus to select from is the Gleichenias, and the best for exhibiting are G. fiabellata, G. Mendell, and G. spalnance. I will add five others to these three, and if one only is selected I would choose the last-named as being the easiest to cultivate: Davallia Mooreana, Dicksonia antarctica, Polypodium hirta cristata,

Adiantum concinnum latum, and *Davallia bulbata*. Six of the best hardy Ferns for exhibition, and such as may be readily obtained, are: *Athyrium Filix-femina* var. *plumosum*, *A. Filix-femina* var. *grandiceps*, *Lastrea Filix-mes* var. *grandiceps*, *Polystichum angulare* var. *plumosum*, *Scolopendrium vulgare crispum grande*, and *Osmunda regalis cristata*.—J. D. E.

It is generally more a question of culture than variety, though of course a well-grown *Adiantum Farleyense* will carry more weight than any of the common *Pterises* or other Ferns which are of similar value. The following six, if well grown, will take a good deal of beating: *Adiantum Farleyense*, *A. cuneatum*, *Asplenium nidus*, *Nephrolepis devallioidea forestans*, *Gymnogramma Mayi*, *Microlepia hirta cristata*, or the following half-dozen are nearly as good: *Adiantum concinnum latum*, *A. Williamsii*, *Platyocarpus alcockii*, *Lemna gibba*, *Pteris nobilis*, and *Pteris argyrea*.—E. H.

Amongst the chief kinds of Ferns grown for exhibition may be mentioned *Adiantum cucullatum*, *A. concinnum latum*, the beautiful *A. Farleyense*, *A. formosum*, *Dicksonia antarctica*, *Microlepia hirta cristata*, *Cyathea decubata*, *Davallia crenariense*, the *Nephrolepis*, and many others. These, however, are amongst the more important, and you will find much information upon them in recent issues of *GARDENING*. It is not a very easy matter to get thoroughly fine exhibition Ferns, such as one sees at the great exhibitions of this country—Shrewsbury, Wolverhampton, &c. If you are going in strongly for them, write again and get advice from "J. J."—C. T.

THE KITCHEN GARDEN.

KITCHEN-GARDEN NOTES.

THE present season will be remembered for some considerable period, for having passed the longest day and no rain sufficient to penetrate 1 inch of soil since the first week in March is enough to explain the more or less entire failure of many crops on which we rely for the coming winter's supply. Potatoes of all early and second early kinds must be a very light crop. Late planted ones, if rain falls soon, may yet produce a fair crop, but Onions, Carrots, Parsnips, and many other things, are looking very miserable, and preparation should be made at once for supplying substitutes or an extra supply of such root crops as can be grown after midsummer. To meet this undoubted deficiency I should suggest that Early Potatoes be lifted and stored at once, for after the skins are set rain will not make them swell any more, but will cause them to grow out wherely they are split for table. The land thus early set at liberty should be at once cropped with the following kinds—viz.,

CARROTS of the intermediate and Short Horn kinds will grow to a good size if sown at once, and they are never so good as when pulled and used fresh from the soil. Don't lift and store them, but cover the bed with a good layer of litter if frost threatens, but if it appears likely to continue, lift a portion of crop and cover the rest.

CAULIFLOWER, Early and Autumn, plant out directly a break in the drought allows, for they fill a gap in the list of first-class vegetables somewhat hard to supply by anything else, and Autumn Giant, if planted in succession, will yield a supply from September until Christmas by protecting the latest planted crop from frosts.

SPINACH of the round-seeded summer kinds comes on rapidly, and makes an excellent green vegetable. It can be grown in rows about 1 foot apart, or grown between other vegetables, such as Peas or Beans.

TOMATOES should receive extra attention as they enjoy heat and drought, and as the fruits can be utilised for salads or culinary purposes in place of other vegetables, they are doubly useful.

VEGETABLE MARROWS are excellent dry weather crops. Keep the soil mulched, and the roots well supplied with manure-water, and do not let any of the fruit get seedy, for they check the formation of young fruits. Plants put out now may produce useful crops.

TURNSIPS should be sown in extra large quantity to meet the great demand that is sure to

arise, owing to the failure of other root crops. Sow the seed thinly in drills, and as soon as the lines are visible thin out to about 1 foot apart.

WINTER GREENS, such as Savoys, Kels, Brussels Sprouts, Cabbage, Broccoli, &c., should be planted out as soon as space is available, or between the rows of second early Potatoes; but unless they can be kept supplied with water for some time after they are shifted, it is almost certain death to remove them, and in many places the supply of water is getting so limited that gardens are likely to get out off altogether, and where this is the case, it will be safer to let the plants stand in seed-bed until sufficient rain falls to moisten the soil.

SHALLOTS, Oerlic, and autumn-sown Onions are now quite ripened off, and should be stored at once, as rain would start them to root again, and detract from their keeping qualities.

JAMES GROOM, Gosport.

VEGETABLE MARROWS.

THESE are most valuable aids to kitchen gardeners, especially in hot dry seasons, for with but a minimum of care they will continue to produce abundant crops when many of the more succulent vegetables are dried up, and a great advantage attending this crop is that it can be grown in positions where hardly any other crop can be produced. I utilise any out-of-the-way corner for rubbish-heaps, and at this period of the year I pack the whole mass into large long ridges placing that which is most decayed on the top, and finish off with a coating of good soil, in which strong plants are at once put out, and abundance of Marrows are procurable until frost finishes off the supply. The following varieties are all good—viz., Long White and Olean, or the running Marrow, is probably the best for most purposes, the fruits are excellent in all stages of growth, and if allowed to ripen off they make an excellent winter vegetable. The Dwarf Bush Marrow produces very fine fruits, but the shoots do not ramble like the preceding; excellent for small gardens. The Curled Vegetable Marrow is very much liked by many, but is not of such a robust habit of growth as the preceding. Pen-y-hyd is the name given to a very prolific variety raised in Wales a few years back; it produces an enormous quantity of fruits, but they do not attain so large a size as the preceding older sorts, but for cutting in a young state it is one of the most useful sorts that can be grown.

J. G., Hants.

WINTER SALADS.

THE advantage of having plenty of the above cannot be over-estimated, and though there is little difficulty in getting salad in abundance in the early autumn there is often a scarcity in the winter and early spring. Of late years there has been mere choice of subjects for the salad bowl owing to the taste for Tomatoes and the greater quantity of Cucumbers that are now grown. In this note I will only refer to such salads as can be grown with ordinary care and at moderate cost. To get winter salads in quantity it is necessary to make preparation early in August, and in cold late districts the sooner the better, as by sowing various seed at this date, such as Lettuce, Endive, and such like, there is no loss if they are sown a little early. If not sown too thickly they may be thinned out to make room for these that are to stand the winter. Many sow earlier than advised, but to do this requires plenty of room to winter the plants. When sown too early the autumn frosts are most destructive to full grown Lettuces, whilst others much smaller are rarely injured. Again, varieties have much to do with hardiness, as some are much more tender than others. Of late years we have had several new varieties introduced that were to withstand our winters, but they are no better than older kinds.

LETTUCE—As this is always in demand for salads, I will give a few words as to its culture in the winter, and those who require it in quantity would do well to depend upon two sowings; some make mere, especially those who require plenty of large Lettuces early in the autumn. To get a regular supply through the winter, beginning in October, I prefer to sow the end of July or early in August, and again the third week in August, and for a quantity of

young plants to put out in the early spring, two or three weeks later. To get Lettuces through the winter, seed should be sown on a dry sloping position sheltered from the east end north, as it is the winds that play such havoc with the plants when on the move after a long winter's rest. The earlier sowings—that is, those sown in August—will furnish nice heads early in October, and as we rarely get severe frosts to do much injury till the end of September, they should then be covered on frosty nights. If there has been delay in sowing for this supply, a little time will be gained by immediate sowing on a warm border in drills 1 foot apart, using the thinnings for a once-over, planting on a warm rich border. Good ground is necessary for this sowing, as a quick growth is required. When these Lettuces are large, if covering is objected to they may be lifted with a good bell and transferred to cold frames or under shelter, piling thickly together. By sowing in drills, there is no delay or check by transplanting. The second sowing in August will prolong the supply through the winter and will require protection or lifting. I generally plant these out of the seed bed much closer than usual, 6 inches apart each way on a warm border, and this is covered with temporary frames, a few lights placed over them, and some boards round the sides. This planting does not give large, full-hearted blenched Lettuces, but nice sized heads, as it will be found large plants decay in the winter months. With a little extra covering in severe weather in the way of mats this lot comes in about the middle of December and lasts some time. To continue the supply through the early spring some of the largest plants from the late sowing are planted thickly in frames, and these commence to grow very early and are large enough for salad, Cabbage Lettuces being the earliest to come in. In a mild autumn these sown now often continue the supply till nearly Christmas and with little protection. The varieties used for sowing for winter are often a matter of opinion, as some growers prefer Cos to Cabbage, but I advise both. I like Brown Cos (Hicks's Hardy Cos to sow early in August), using the Brown or Bath for the later sowing and to stand the winter. Of Cabbage varieties there are no better for winter than Hardy Hammersmith, Victoria, and Stanstead Park. I like the Cabbage varieties to sow late for early spring use as they come to sooner than the Cos. For the late sowing to remain in the seed-beds or to prick out thickly into frames, the Hammersmith and Stanstead Park are good. After housing or lifting the winter supply, it is necessary to air freely and keep free of decayed foliage. Even those who do not possess frame protections may have good Lettuces till late in the year when covered with mats or canvas. I often utilise dressed covers for this work, or rough wood supports, unrolling the canvas night and morning, and if a late lot of plants is secured on a protected border, these give a much earlier supply in the spring than plants raised to heat, and when a few can be planted early in the year in boxes or on warm leaves, they soon come in. Many shifts can be adopted to raise material for the salad bowl, as if short of Lettuces, a few pans or boxes sown in mild heat every few weeks, and cut over like Mustard and Cress, furnish nice salad at little cost, a quick-growing variety being used for the purpose. Last spring I found Golden Queen and Harbinger very good for the purpose.

ENDIVE.—I have devoted more space to Lettuces on account of their being liked by nearly everyone. Endive is not so popular, but a useful salad, and next in importance to Lettuce, being readily grown and sheltered through the winter. Much the same treatment is required, except that it is not wanted when there is plenty of Lettuces; but, growing freely in the late autumn, it is most useful. To get it large requires early sowing, that is early in July or earlier, but large Endive does not winter well. It is necessary to lift as advised for Lettuces, so that a large quantity early in the autumn requires a lot of room for shelter. I prefer to sow now, and to get medium-sized plants by October; these will then stand a certain amount of frost, and may be lifted later to take out the supply of Lettuces. If a quantity is required a sowing early in July is essential. These may be wintered in frames, lifting as advised for Lettuces, or they may be protected on the open border by covering. I usually plant a good

quantity rather close and protect with litter or mats, and if not too large they do well. Protection may also be afforded by tying up the plants and placing litter between them. There is no gain by sowing Endive too early, as it often runs to seed, and for plants to remain in the open not lifted, the Round-leaved Batavian is the best, very hardy, a compact grower, and readily blanched in the winter if placed in a Mushroom-house. The Green Curled varieties, though more showy, are not nearly so hardy. For an early autumn supply the green and Moss Curled are nice, but the latter will not stand frost. I consider the Green Curled and Round-leaved Batavian the best of all, using the first for the early lot and the latter for mid-winter use.

CORN SALAD is not used so much as it deserves, it being a valuable adjunct to the salad bowl and easily grown. I prefer to make two sowings, a large one early in July and one (a smaller) first week in August; this latter on good land and sheltered and well supplied with moisture, during severe weather throwing a little dry litter over the bed. In the summer this variety is not required with plenty of choice subjects, but in winter it is useful and of easy culture, the Broad-leaved Italian being the best variety. Chicory, a useful plant and easily grown, should be sown early in June, and the roots stored and forced in the winter months. It will give a lot of cutting, and half-a-dozen roots placed in a Mushroom-house fortnightly will give a good supply. When sown too early, especially on light soils, the plant runs badly. The large-leaved or Witloof is the best variety. Dandelion requires the same culture and to be forced, and is valuable for the salad bowl during the winter; indeed, with plenty of Dandelion, Endive is not missed. The value of Beetroot is too well known to need any remarks, and as the last named requires attention earlier in the season to get the roots large enough, I merely note its value as a winter salad. I would point out the value of small Beet for this purpose; and if Dell's Crimson is sown in June, it is of a useful size by the autumn, and keeps good a long time. I do not like coarse Beet mixed with green salad. Celery is equally useful in the salad bowl as in a plain state, and when the blanched tops are used they give a nice flavour, besides eking out the material in the spring when short of green salad. Mustard and Cress should be sown every fortnight. Watercress may be had all through the winter by sowing seed in pans or boxes and growing in frame, or it may be sown broadcast in frames and well supplied with water. I have also grown it in pots, pricking off a few seedlings into 4½-inch pots, and growing close together near the glass in a temperature of 55 degs. to 60 degs., watering freely in bright weather. Early in the year the last-named plan is useful to get early Watercress, and when cut over it continues growing, and may finally be planted out in a shady place for a summer supply. G.

better, with a rise of 10 degs. during the day. Regular attention to trailing and pruning the plants is absolutely essential. Cold water is a source of evil; that which is tepid should be used.—S. P.

— Probably the Cucumbers require more nourishment. Try them with artificial in the water; one ounce to the gallon.—E. H.

Potatoes and manure.—It is only where manure has been applied with a free hand that this, or for that matter any other crop, is making anything like satisfactory progress this season. As a rule, I am by no means an advocate—quite the reverse—of using stable or farmyard manure in direct contact with Potatoes at planting time; but where this has been done, and applied liberally, the growth and promise is far in advance of those planted in other ways. A man who annually grows a field of Potatoes near here has the last two years had them planted by taking out for each row a square trench in much the same manner as for Celery—that is, flat at the bottom and about 9 inches wide and deep. These were filled full of manure (London dung), the sets being laid on the top, and covered with the soil shovelled out of the next trench. These Potatoes are now growing and promising better than any others in the neighbourhood; but if we get much rain from now onwards there will be a lot of disease among them, no doubt. Early Potatoes are turning out very badly here (in

Chicory, blancheted.

Sussex). In most places there is not a quarter of a crop. Fortunately, I think, I did not plant my main breadth until quite the middle of May, and if the rain comes kindly now, just as the tubers are beginning to form, they will do far better than the early planted lots. I have just given them a sprinkling of ammonia sulphate, which ought to make them move.—B. C. H.

4061.—Stachye tuberifera—This excellent does not take up much space, as the plants do not grow more than about 18 inches in height, and they are planted in good, rich garden soil. I plant them in lines about 18 inches asunder, and allow 12 inches between the plants. The tubers are in good condition to use in September, and they may be dug up for use all through the winter months; but the quality is not so good when they are used in January and February. They are certainly best in October. I do not earth them up at all. It is only necessary to cover the tubers if they should appear above ground, but they do not.—J. D. E.

— The cultivation of this plant is of the simplest kind. The tubers should be planted in drills 3 inches deep, and about 9 inches apart, the drills twice that distance. The plants do not require earthing like Potatoes, and they grow about 15 inches high. Your plants being only 3 inches in height at the present time it is plain they are suffering for the want of root moisture. If the dry weather continues give them a good soaking of water once a week.

The largest tubers are about 2 inches in circumference, and a little more in length. As a vegetable it is a poor thing. In that respect it is not equal to the Chinese Yam. Its only merit is that it makes variety in the winter season. If you take the tubers out of the ground before you want to use them you must keep them away from the air, or they will quickly shrivel up.—J. C. C.

INDOOR PLANTS.

4050.—Shading for a greenhouse.—Fresh lime, mixed with water, so as to make a rather thick wash, is very commonly used for shading, and answers sufficiently well, though, I believe, that in time it eats into the surface of the glass to some extent. A mixture of whitening and water may also be used, and has a cleaner and better appearance, but a small proportion of milk should be added, or some size be dissolved in part of the water, made hot, or else it will be all washed off by the first rain. Flour and water only (not paste), mixed smoothly to the consistence of cream, makes a capital shading, as when wet it becomes semi-transparent, and, consequently, admits more light to the plants beneath on rainy days, but as it throws only a light shade it is sometimes necessary to mix a little whitening with it. Any of the above may be put on with a broad flat brush (a soft house broom will do), or if not too thick may be distributed with a syringe having a coarse rose on.—B. C. R.

— Elliott's Summer Cloud is by far the best material for a permanent shading; but roller blinds are better still. During dull weather the plants are benefited by all available light. In the case of movable blinds they can have it. Flour made into the consistency of paint with clear, cold water, and put on to the glass with an ordinary paint brush, choosing a dry day, is the best cheap shading that I know; it will not wash off for some months. Lime made hot will adhere to the glass for a time, but is injurious to the paint where it touches it.—S. P.

4047.—Blinds for conservatory.—Tiffany is undoubtedly the best material to use for shading a conservatory. As you say the structure is a large one, are you wise in wishing to place the blinds outside? I think not, as there will not only be some difficulty in fixing and working them, but you will find a rough wind blow them into shreds. There is no more difficulty in fixing blinds inside than out, to be drawn up and down. Movable blinds are, however, not wanted for a large structure. If the Tiffany is fixed permanently for the season to the rafters inside that is all that is required.—J. C. C.

— If the house is very large you will find blinds rather expensive, although they are the best kind of shading, as they can be regulated according to the weather, and the plants are never in perpetual shade. During the early summer, for instance, it often happens that the sun is fitful. Tiffany is the best material to make the roller blinds, and get it as white as you can, so as to admit as much light as possible. The old idea of heavy shading has long been exploded. If deprived of a fair share of light plants suffer severely.—C. T.

— What is termed Rot-proof Scrim makes a lasting blind, and the shade is quite dense enough for all flowering plants or Ferns. I do not think anyone requiring blinds can do better than write to Edgington for samples and prices of different materials.—E. H.

Carnations and drought.—These beautiful summer flowers have withstood the trying ordeal of over three months' drought, and are now flowering splendidly; in fact, better than any other class of hardy flowers I grow. I cannot say that the individual blooms are fully up to size, but for height of stem and quantity of bloom they are fully up to the average. My soil suits Pinke and Carnations well, being a light sandy loam of good depth, in which layers strike root readily without any addition of fresh soil. I may add that I have not used artificial watering, having so many other things that were really dying for want of water while the Carnations look vigorous, but I have kept the surface frequently hoed and raked, as I find a good layer of finely powdered dust on the surface one of the best means of saving them in hot weather.—J. C. H.

4057.—Cucumbers in a greenhouse.—As a rule, Cucumbers do not succeed so well in pots as when planted out, certainly during the height of summer, when it is so difficult to keep the roots sufficiently moist without making the soil sour. How large are the pots? If 12 inches or more in diameter it would be as well to plunge them in, or surround them with, a bed of fresh tan or spent Hops; if smaller, better remove or break away the pots and surround them with rich turfy loam, well drained, and made firm—to plant them out, in fact. Possibly the growth is too crowded and weak to perfect fruit. Of course, they get plenty of nourishment in the shape of liquid manure.—B. C. R.

— There are various causes for the premature decay of Cucumbers, such as overcropping, dryness at the root, also stagnation about the roots, caused by too much moisture or the want of proper drainage. Again, another great source of the small fruit turning yellow is fluctuation of the temperature. If no fire heat is employed on a cool night exceeding a hot day the plants receive a check, which results in a stoppage of growth, causing the small fruit to decay prematurely. This is the primary cause of defective cultivation in greenhouses. To succeed with Cucumbers really well the temperature should never fall below 65 degs. and should not

ROSES.

OWN-ROOTED TEA ROSES.

TEA ROSES on their own roots are best, because if well cared for they are virtually indestructible. Place a little ridge of burnt earth or something similar round the base of each plant when first set in, and there will always be life below ground that will push out vigorously should the top be injured by stress of weather. But many planters of Tea and other Roses do not give their plants a fair start at first. The soil for Teas must be deep, well drained, and fairly rich, though strong, rank manure is not desirable, as its tendency is to make the soil close and sour. A good many years ago I turned out a lot of home propagated Tea Roses in various positions. That season I remember I had an abundance of home-grown Teas, mainly because there was a better lot of cuttings to work upon. One lot, consisting of Catherine Mermel, Niphotos, Homère, Marie van Houtte, and other kinds, was placed along the front of a Vine border, where the soil was deep, well drained, and rich. With the exception of Niphotos, these plants along the front of the Vine border did famously, and formed immense bushes from which a supply of fine blooms could always be obtained. Another hatch of plants was set out in a warm south border, and these also were a success, producing the same year they were propagated beautiful blooms. Other plants of similar sorts were placed in various positions, but the plants on the Vine border were the most successful. I have long held the opinion that for anything we wish to grow well it is both better and cheaper to thoroughly prepare the ground first, and Tea Roses must have a dry, warm, deep bed. The

PROPAGATION OF TEA ROSES under glass is as simple as striking Verbenas, and well-nigh as successful. Cuttings which have been obtained from plants under glass are firmer and riper than any growths made in the open ground can possibly be, though as regards the selection of the wood for cuttings, I do not care how old it is. In a propagating bed where there is a temperature of 75 degs. to 80 degs., and an atmospheric heat of 60 degs., all cuttings, except those which are very soft and young, will strike with a small percentage of loss. I think cuttings from wood of more than one season's growth are even better than younger stuff; at any rate, it is a decided advantage to have a heel of old wood at the base of the cutting. Cuttings may be rooted from single buds, but unless the buds are strong the growths they make will be weak, and it takes a couple of years to make them into plants. I have struck Teas and other Roses in pots plunged in Cocoa-fibre in a genial bottom-heat, and I have rooted them by simply thrusting the cuttings into the moist fibre without potting, and have invariably obtained more plants from the same number of cuttings when pots are not used for striking. The reason is, I think, obvious; Cocoa-fibre is always in one even condition as to moisture, and that condition can be maintained from the time the cuttings are inserted till they are lifted for potting without having received any water beyond a very light dewing over during the process of rooting. This equable condition of moisture without the use of the water-pot is worth everything in the work of propagation. Water kills more cuttings than all other causes of loss put together. I like good-sized cuttings, but the wood is too valuable to use big pieces, and by the one-hand or eye system one has to wait a long time for strong plants. This is why a grafted plant has an advantage over the own-rooted plant at first, but as the years roll round the advantage is on the other side. It is true that in course of time if the stocks are hurried in planting the Rose forms roots of its own, and then, I think, the stock begins to become an embarrassment, and would be better away. As regards layering Roses, it is a very old and a very good process, but it is slow. Many years ago, when it was the fashion to have large beds of Roses in gardens of one kind, such as the Provenço, York and Lancaster, Maiden's Blush, and other old sorts which are now being sought for again in some places, the beds were always kept full by layering the strong shoots, this being usually done in February. So far as regards open-air propagation, layering is decidedly the best plan to adopt, and when the

strong old plants of the best and hardiest varieties have been obtained, there will be plenty of own-rooted Tea Roses with hardy constitutions. H.

BUDDING ROSES.

JULY and August are the two best months for budding, the former month being preferable; but in cases where large quantities have to be done, or the stock of any desired variety is small and weak, it must depend in a great measure upon when one can find the buds. To ensure a fair amount of success all stocks should be budded before September, as the sap on which the bud enters itself does not flow so freely after that time, and consequently the bud has not so good a chance of getting "set" to the stock. I prefer the stocks to be growing fairly well, not rampant, or the bud is flooded with too much sap. It is well to have them of medium growth only, and to secure this end I never manure my stocks when planting, finding they grow quite strongly enough for successful budding without any such assistance, and that a steady summer's growth tends towards setting the bud earlier and firmer, both of them getting more matured and better able to withstand winter frosts. If grown too strongly, the bark sometimes swells completely over the bud, smothering and so killing it. This last point applies more particularly to the seedling Brier, a stock that often swells from the size of an ordinary knitting needle to as large as 2 inches in circumference, if growing at all strongly and upon rich ground. Supposing, then, that the stocks are not on too rich a piece of ground, they may be budded as soon as sufficient sap has risen to allow the bark to be easily lifted. Let the Rose-shoot you intend working from be as nearly as possible in the same stage of growth as the portion of the stock you are operating upon, so that they may heal over and unite more perfectly. If this be attended to, they will be set in from two to three weeks, when they may be looked over and any failures rebudded a little higher up the stock. By getting this operation done fairly early in the season fewer failures will result, and one has the opportunity of inserting a second bud where failure has attended the first attempt. It is by no means necessary to have prepared stocks for budding upon, as any strong growing Rose may be converted into a more desirable variety. Where a good plant of any inferior kind exists it is sometimes better to bud a more desirable kind upon it than to destroy it and replace with a nursery-grown plant of the favoured sort. In many cases one has a plant under glass that is growing vigorously, but is unfortunately of some little-desired variety. Almost any variety of Rose will do excellently upon such a stock, and it would be wise to so utilize the established roots of such Roses.

THE MANETTI is one of the staple stocks for dwarf Roses, and if properly budded they will do excellently upon it, and not produce the quantities of suckers too often found upon plants worked upon this stock. Some time ago I advised that all dwarf stocks should have a little earth drawn up to them. If this plan has been followed, the benefits accruing from it will be very patent during the budding season. Before inserting any buds remove the soil as much as possible without injury to the stock, getting as near to the crown of it as you possibly can. Let this operation be done very carefully, so as not to bruise the bark. The lower the bud can be got the better will it be as regards suckers, as you thus leave a very small portion indeed of the original stock to produce them; otherwise they are almost certain to emanate from the space between the bud and crown of the stock, robbing the Rose, and unless constantly attended to eventually resulting in the death of all but the stock itself. On the other hand, if properly worked, very few suckers can result, and the Rose is much more inclined to strike off upon its own roots, and thus receive additional support to that afforded by the stock. In the case of all dwarf stocks, one bud to each is quite sufficient. Seedling and struck cutting Briers may be treated exactly the same as the Manetti; so also may the De la Greffierie and any of the Polyantha or other Roses that are grown from cuttings in the same way, and which are much used by some few amateurs as

HEDGE BRIERS for standard and half-standard Roses require somewhat different treatment, although the actual operation of budding is the same. As soon as the Briers in this form commence to grow, remove all of the young shoots, except the two or three you intend working a Rose upon. The exact height of these must be decided on according to the height you wish your future Rose-tree to be. When the remaining growths are a little thicker than an ordinary lead pencil and the bark at their base is efficiently matured, they should each have a bud inserted into them and as near to the main stem as possible. One bud in each of the two or three shoulders will be sufficient. We now come to a very important point in the operation of budding Roses—viz., what stock to work certain varieties upon. All Roses, of what-ever class, will do well upon either of the Brier stocks; but it is best to put only strong growers upon full standards of the hedge Brier, as the weaker kinds do not possess sufficient strength to keep the Brier roots in active growth and the stem healthy. It will not do to allow suckers to grow out occasionally with this object in view, as they would soon take the whole of the sap, and the Rose itself would dwindle away and die. The majority of the Hybrid Perpetuals, Bonbons, Mosses, and strong growing Tea-scented Roses do well upon the Manetti, notable exceptions among the first being Captain Christy, Xavier Olibo, Marie Verdier, Sultan of Zanzibar, and Her Majesty. The actual operation of budding may be carried out by the most inexperienced with fair prospects of success if done cleanly, quickly, and neatly, after a flower has been cut from a shoot about a week or ten days and the remaining eyes are nicely prominent without being actually started into fresh growth is an excellent time for budding, also when the prickles of a half-matured shoot will snap off readily when touched. If these hang to the bark, as a general rule the bark surrounding the bud will hang too, and this would necessitate too much force in removing the small portion of wood. It is essential that the bud be in as nearly a ripe condition as possible consistent with an easy and free removal of the wood from the bark, also that the seat of the eye be on level with the bark and so rest upon the wood of the stock. R.

4067.—Preparing ground for Roses.—A stiff soil resting on clay is the very ideal of a soil for growing Standard Roses, and for dwarfs on the Brier-stock. Never mind about its being poor, you can enrich it with manure. You need not disturb the subsoil unless the clay retains water, but dig over the space two spits deep and mix plenty of manure with the soil as the work proceeds, not forgetting to leave a thick layer of 8 inches under the surface. In a bed 4 yards wide you may have two rows of standards on 2 foot stems, and two of dwarfs on each side. The fact that the White Rose of which you speak thrives so well proves what I say that your soil is very suitable for Roses, and if you get it up to a proper condition as regards the application of manure, you will find that even standards will live and flower grandly for a number of years, especially such varieties of H.P.'s as Merville de Lyon, Boule de Neige, General Jacqueminot, Captain Christy, Alfred Brunnner, Madame Nachary, and Duo de Rohan. The ground should be prepared at once, and the Roses planted early in November.—J. C. C.

Trench the ground up from 2 foot to 3 foot deep, but do not bring any of the bad subsoil to the top, though. A layer of manure should be placed on the top of the broken-up bottom spit. When the whole has been trenched up give the surface a heavy dressing of the best manure available, and fork or dig it in. Do the preparation work now, and leave it to the action of the weather till November, and then plant. The reason why so many people fail to grow Roses well is in the lack of preparation at the beginning. Roses will not thrive with their roots thrust into hard, unmoved, unmanured land.—E. H.

In one point you are at least fortunate—viz., that the soil you describe is just the thing for Roses, and with proper preparation and due care afterwards you may look forward to a perfect feast of Roses in the course of a year or

two. You had better commence by trenching the ground well to the depth of three spades; but do not bury the top spits—throw it on one side, and keep it still on the top. The turf may be pared off 4 inches thick, and be stacked up by itself; when partly rotten it will do capitally with a little leaf-mould to work round the roots when planting. Throw some brickbats or the like in the bottom of each trench and if the water "lies" about put in a drain to carry it off. Work in plenty of rough manure in the the third spit, and some of a finer nature near the surface. It will still further improve the ground to burn part of the clay with small coal or wood, and use the rough ballast down below, and the fine siftings near the top. Take care to employ the plants on the Brier-stock only; the Manetti is useless on such soil. Plant in October.—B. C. R.

— As your soil is poor but stiff, and of such a uice depth as 3 feet, there should be little difficulty in getting it into good order for Roses. I would not use any marl in your case, nor

will be at hand to fill it in and so finish. I cannot think that your soil is quite so poor as you imagine, seeing Strawberries are growing so strongly.—P. U.

— It is necessary to have a good moderately heavy loam, especially if fine typical blooms are desired. It is useless to grow Roses in poor ground, and if the staple is naturally sandy, wanting in fibre, so to speak, then new soil must be brought to the garden. If a few beds are to be planted, first get the ground in readiness, not forgetting to dig in a fair allowance of manure, working it thoroughly into the ground. If left in lumps, little benefit is received by the plants. In soils at all poor there must be an ample allowance of manure—not the kind of material one uses in a hot-bed, but good cow-manure. Always take the greatest care in planting. A distance of 3 feet is, as a rule, sufficient for the plants to be apart, but much depends, of course, upon their size, in the variety. When planting, spread out the roots carefully, and place a little of the finer part of

sufficiently matured, or you prune it back too hard each season. Which of these causes it is in your case you must judge for yourself. With me it is one of the freest of all Roses, and it by no means a difficult variety to ripen. If you have been cutting away the long growths, you have also been removing the best of your flowering wood, provided it was fairly well ripened.—P. U.

THE HOUTTYNIAS.

A SMALL genus, containing only three species of very remarkable plants, they are nearly allied to *Saururus Loureiri* and *S. cornus*, and are the only hardy representatives of the natural order Piperaceae. They are beautiful and graceful as well as curious plants, and are well suited for the bog-garden, where in a rich peaty soil they present quite a tropical appearance. They are all perfectly hardy in the south, at any rate, and may be increased readily by division.

H. CALIFORNICA.—This very remarkable plant is also known in gardens under the name of *Anemionis californica*; it is now, however, placed under *Houttynia*, and along with other two species forms the entire genus. It was first found by Nuttall at San Diego, Upper California, and later by Douglas, who sent specimens home. It is a true perennial, the leaves nearly all rising from a fasciculated rootstock. They are always on long stalks, the blade elliptical, nearly cordate at the base, blunt, and the edges entire. The flower-stem is very hairy, erect, longer than the leaves, and bearing numerous small inconspicuous flowers on an oval cone. This is surrounded by six large spreading bracts, the inner three spotted with red, the others white. These bracts are very persistent, and remain fixed long after they have turned brown. It is a useful plant for the bog-garden and very easily managed. Increased by division. It flowers June to August. The accompanying figure gives a good illustration of a robust specimen.

H. COMATA, figured in the *Botanical Magazine*, 54, tab. 2731, is a perennial, with a stout creeping root throwing out a few fibres. It is quite distinct in habit from the above, the stems growing from 1 foot to 2 feet high, erect, and rarely branched, the leaves alternate, cordate at base, pointed, with entire margins. The spathe or bract resembles a corolla, and consists of four large pure-white spreading leaves from the base of the spadix or cone of flowers. Thunberg first found this curious plant in Japan, where it appears to be known as *Dokn Dami*, or *Kijun-ki*, growing in abundance in ditches by the wayside. It is also found in Nepal and Cochin China, where Loureire found it only growing in gardens. A useful companion to the above, flowering July and August.

H. CHINENSIS, which was first named *Gymnotheca chinensis* by Decaisne, is a native of China, and appears to be a very ornamental plant. I have not seen it in cultivation, though apparently well worth it. D.

Primula sikkimensis.—There is doubtless much variety in this species. I have had plants with very thin scapes 3 feet high, but the most glorious specimen I have ever seen was a plant with upwards of thirty stout scapes about 18 inches high, some having as many as thirty flowers upon at once in an evenly-balanced umbel, and all the scapes carrying bloom at the same time, continuing to do so for more than a month, and to-day in very good form, after the very rainy and windy weather. I particularly mention this plant because it is at least five years old, and some of us have hitherto imagined that good results could only be had with younger plants to be raised annually for succession. The plant, I may say, has not been grown in a wet place, but an ordinary border, screened, however, from midday sunshine, where doubtless it runs a steadier and longer life course.—W.

4061.—A plague of cockchafers.—Possibly others will give you better advice, but I was troubled similarly once with this pest, and the remedy was to syringe with water in which was placed a little soft-soap and paraffin—a very small quantity of the latter. They did not care for this reception, but the great thing is not to use the preparation too strong, otherwise the remedy will be worse than the evil. Nothing

Houttynia californica. Engraved from a drawing sent by Mr. C. A. Orrell, California.

would I turn the soil to the top. If you "bastard-trench" the ground well, and add a fair amount of manure, I do not see that it will be necessary to do anything else. Bastard-trenching consists of the following operations: Take out a trench from one end of your plot, say about a foot deep and eighteen inches wide. Remove this to the other end of your plot, where it will be ready for filling in the last trench you open. Having removed the first foot of soil spread a good layer of manure in the trench, and proceed to turn the subsoil bottom upwards, working it as deeply as your spud will allow. Pig-manure is about the best you can use, but any well-decayed dung and rubbish will answer. London manure is also very good, containing a much larger proportion of droppings than ordinary farmyard manure. Now set out another breadth of 18 inches, and as each spit is lifted let it be thrown over into the open trench by its side. Shovel up the loose soil from the trench you have formed last, manure and turn over the subsoil, and so continue until you arrive at your last trench, when the soil already carried there

the loam over them, into which they will send their delicate fibres. Thick roots without fibres may be cut back hard, but use the knife cautiously. Bold surgery of this kind is easy to perform, but injudicious "hacking" can never be remedied. Avoid deep planting, covering the roots with about 4 inches of soil, and if the trees are standards place a stake firmly to each, to prevent the stem swaying about in the wind. It is essential not to disturb the roots, otherwise they will never take hold of the soil. The best time to plant is late October, as the soil is then in a sweeter condition, moderately dry, as a rule, and the trees have a fairly long season to recover themselves before they meet the trials of winter. A dressing of well-decayed manure on the surface will not be money wasted.—C. T.

4058.—Rose W. A. Richardson.—I would rather see a Rose so recently planted grow freely than flower over much. The Rose is doing well enough; let it grow, and train in all the strong shoots. It will flower in due time.—R. H.

There may be two reasons why your plant does not bloom. Either the wood does not get

ORCHIDS.

ZYGOPETALUMS.

"MARK HUNTLEY" asks me to give him some advice about these Orchids? Now, if I do this I shall confine myself patriotically to the old genus as founded by Hooker, and I think this is what my friend means and wants. Indeed, he refers to the very type species, *Z. Mackayi*, for the genus is used in the present day for anything that one does not know, just calling it a *Zygopetalum*, and there is an end of the trouble. However, I do not profess to know the plants with the accuracy of a Bentham or Hooker, but I will here just record some few of this old genus, which will not require much care in their culture, and which will give you a host of beautiful flowers in return, which last a very long time in perfection either left upon the plants, or they may be cut for the decoration of the rooms of the dwelling-house, or they may be used for purposes of personal adornment, and in each and in every position they may be made to fit pleasingly and well. These plants are strong growers and large rooters. They, therefore, require a larger space in which to ramble than do many of the Orchid family. They require a large amount of drainage material, for as these plants require a quantity of water during the growing season, so must this be enabled to pass away quickly from the roots, so that everything about them may be kept in a sweet and clean condition, for without this it is done you cannot look for success, and this indeed being neglected is the cause why I see these plants fail to give satisfaction to so many. They want a fairly light situation, although they do not like the bright sunshine, therefore shading should be provided to be on over them when this luminary shines. For soil use about equal parts of good peat-fibre and chopped Sphagnum Moss, and in potting the plants use some sharp sand amongst it occasionally. Pot the plants upon a small elevated mound, and press the base firmly about the plant. Some persons take the plant out of this soil every season, but I do not hold with this plan, as a rule, to be adopted; neither do I appreciate those careless growers' system who will allow the plants of this genus to grow year after year and never give heed to the renewal of soil until the plants get weaker and weaker, like my friend, "Mark Huntley's," and they refuse to flower, this being the second year they have omitted to send up a single flower-spoke. In the growing season they like the heat of the Cattleya-house, with somewhat more shade, and the syringe may be used more freely upon them than upon the Cattleyas, and with a much larger amount of water to their roots, and in the winter months any house with a fair amount of moisture in the air, and a temperature of 58 degs. or 60 degs., as the lowest reading, will suit them admirably. Treated in the above manner, renewing the surface-soil every spring, and picking carefully away any decaying or sour soil, I think no one would have the slightest cause to complain that their plants of *Zygopetalums* failed to produce flower-spikes.

Z. MACKAYI.—This plant is mentioned in my correspondent's letter, and therefore I put it first on the list; moreover, it is the finest in the series here given. It has been a constant plant in our stoves, I think, for nearly seventy years, and I do not think has ever been lost to cultivation since its first introduction by the worthy man whom it commemorates. I have seen some splendid specimens of it bearing many spikes, some 3 feet and 4 feet high, bearing many flowers, each of which measured fully 3 inches across, the sepals and petals being yellowish-green, blotched with brownish-purple, and the large lip spotted and thickly streaked with purple or violet, and which last a very long time in perfection, yielding a delicate and grateful perfume in the autumn and winter months.

Z. INTERMEDIUM is similar to the above; indeed, it is frequently to be found in gardens under the name of *Mackayi*; but, however, may be distinguished from *Mackayi* by its smaller form, its longer, narrower leaves, as well as by its shorter spike and smaller flowers, the colours also are more or less duller, but it is a very beautiful plant.

Z. CRINATUM.—This is a plant which frequently is called a variety of *Mackayi*, as likewise is the last. This may be the case in fact, but the present plants are very distinct,

inasmuch as the flowers much resemble the typical form, but the plant is very much dwarfier, the spike, too, is also shorter; indeed, this may be grown by persons not having room to accommodate such a large plant as *Mackayi* hooceae, whilst the flowers, which are very little inferior in size, but fewer on the spikes, are similarly coloured. There is, however, a variety of this plant which has rosy-red or crimson stripes in place of the blue or violet. Amongst other kinds there is *Z. rostratum*, having very large white flowers; it, however, requires greater heat, and does not grow with the kinds previously mentioned. *Z. maxillare* is a smaller flowered kind, having a lip of bluish-violet, but it requires to grow in the stems of Tree-Ferns, and is, therefore, not recommended to the amateur grower. *Z. graminifolium* is another plant similar in colour, and with just the same habit; it is a beautiful little species, for which we have to thank Mr. Sander, of St Albans, for introducing to our notice, but it is scarcely an amateur's plant, whilst *Z. Burkei*, introduced by the Messrs. Veitch, of Chelsea, with its white lip and green sepals and petals, stands somewhat in the same category. I think I have brought before my readers' notice the heat of the showy species and varieties, and those, too, are the easiest to grow, so with the above remarks I hope my friend "Mark Huntley" will be satisfied and be able to get on with his *Zygopetalums*. MATT. BRAMBLE.

RODRIGUEZIA SECUNDA AND OTHERS.

This is a very old and pretty Orchid, and a somewhat variable kind in its depth of colour. The spikes sent me by "M. Johnston" are very bright and showy. It is widely spread over tropical South America, consequently it may be expected to vary somewhat; but the plant first became known to us from the Island of Trinidad, and it used to be a frequent occupant of any box of Orchids received from South America in my young days, and I observed that the plants that came from the warmest parts were usually the deepest in colour, and I found that during their growing season they liked to have a good heat, and to be kept in a very moist state, and during the resting season their hulks must be kept in a fairly moist condition, and not subjected to the drying influence which was so prevalent in the earlier days of Orchid culture, when every Orchid had to have a decided dry season, and be shrivelled; but now a better system is adopted, for by lowering the temperature, the plant or plants can be kept and rested far better, because they can be furnished with sufficient moisture to maintain the growths in a plump condition, and this enables them to start away and grow with strength and vigour at once, without the expenditure of time, in making up the growth, or having the new growth from a shrivelled and worn-out old hulk, and these shrivelled and worn-out hulks render the plants so old and worn-out looking, and it gives them such an untidy appearance. I recommend the lady who writes to me to grow this plant in a hanging position, either in a shallow pan, a small basket (see our p. 267), or upon a hloek of wood, and I must confess I like the hloek system the best for this plant, and I use for it Sphagnum only in this case; but if a small shallow pan be used I would drain it well, and I would use with the Moss some little good peat-fibre, from which all the fine soil had been removed, potting it very firmly, for I have so frequently seen this plant go wrong from being so loosely set in the soil, and this is one of the chief reasons why I like hloek culture for this and many other of these small-rooting plants, because they can be kept firmly fixed by the copper wire that is used in fixing them. *Rodriguezias* like an abundance of water, the heat of the Cattleya-house, and a nice moist atmosphere during the growing season. The following are one or two of the best and most floriferous kinds:—

R. SECUNDA.—A small-growing plant, having small hulle and dark-green leaves, which form a beautiful background for the sanguineous flowers, which are thickly set upon the short spikes, and which all stand in a one-sided fashion.

R. CANDIDA.—Now this plant I need to grow under the name of *Burlingtonia*, but according to the modern theorists the latter genus is a synonym, and so for once I accept this theory

and adopt the new order of things. This plant is a stronger grower than the last named, but I like for this plant the hloek system of culture best. The flowers are produced on pendulous spikes, they are large and of the purest white, with a stain of bright-yellow on the lip. It is a most desirable plant.

R. FRAGRANS.—This plant resembles the preceding species in the colour of its flowers; they are about of equal size, and they yield a most delightful fragrance which much resembles *May-hlossom*.

R. VENUSTA is a plant which is smaller in its growth than the last-named although I have found some folks who make them to be the same species, but with this I cannot agree. The flowers are not half the size, they are pure-white, stained with yellow in the lip, and they do not possess any fragrance which renders the last-named kind so very welcome, especially by the ladies. The above-named plants are all worthy of a place in any and every collection of Orchids, and all of them will thrive admirably on good-sized hloeks of wood.

MATT. BRAMBLE.

4052.—**A garden fence.**—There is nothing better than a good Holly-hedge, but it grows so painfully slow at first, especially on some soils, that one hesitates about recommending it. If the fence forms a boundary, evergreens, such as Yew-tree or Arbor-vita would hardly do, or else they are capital shelters and blinds. White Thoro and Privet in mixture makes both a good shelter and grows rapidly, and when well established will form a good fence against stock.—E. H.

—This question is not very clear, as there is no information as to whether there is an existing fence or not, and if protection is wanted outside of the present boundary. A close wood fence 6 feet high is very suitable for a garden, but it does not give much protection against spring frost. Supposing there is an existing fence, a line of Lomhardy Poplars beyond that will quickly grow into a thicket, and afford shelter sooner than anything else. If planted out 4 feet apart they can be grown in the form of a hedge any height or thickness you want.—J. C. C.

—There are so many kinds of quick-growing subjects suitable for fences that it is difficult perhaps to choose the right one for all positions. Thuja Lobbi is perhaps the one that will grow the fastest up to 30 feet high if needed, and it makes a capital screen also. The common English Yew is another quick-growing evergreen, preferable to any other where a fence up to 10 feet high is required. Common Holly makes a thick and warm screen, but does not grow so fast. Portugal Laurel is another fast-growing subject, but requires more space in width. Evergreen Privet is of rapid growth, but is not quite so firm as the others; still, it makes a good screen. Quick is undoubtedly the best of all hedges where cattle are kept, but some years are required to get a really good Quick fence. Whatever is chosen, all the difference is made in its progress by the manner in which it is planted. The ground should be trenched 18 inches deep at least, and plenty of manure added at planting time, not hurrying it too deep either, afterwards mulching the surface to prevent evaporation of moisture from the soil during the summer. With the exception of the Quick all the other subjects are best planted in the early part of April. Should dry weather set in for any length of time during the months of May and June the plants will need attention in watering. Whatever pruning is required should be done in February, or March at the latest.—S. P.

4028.—**White-flowered plants for cutting.**—If you exclude trees and shrubs, the hardy plants that flower before the Pinks are mostly of low stature. The Double White Rocket and Brompton Stocks might possibly flower before the Pinks if they were given a warm position. The Perennial Candytuft (*Iberis coronifolia*) and Snow in Summer (*Cerastium tomentosum*) are two low-growing plants that may help you with white flowers. Amongst shrubs that bloom early I may mention the White Lilac, *Dutzia gracilis*, and Syringa.—J. C. C.

TREES AND SHRUBS.

CHOICE SHRUBS.

RETINOSPORA AUREO RETICULATA.

CONIFEROUS plants do not, as a rule, do at all well in a town garden; but this plant (here illustrated) is quite an exception to the rule. For window-boxes, when the plants are young, or for a lawn this Japanese Conifer has no superior. It should be much more largely planted than is the case at present. B.

PLANTING EVERGREENS IN SUMMER.

I AM not aware that anything new can be said in favour of planting evergreen trees and shrubs during the summer months. The questions bearing on this matter are two—the probable results as compared with spring planting, and the effect that a hard winter has on newly planted subjects. As regard the first, I have no hesitation in saying that the best results will be obtained from summer planting in all cases where the plants to be moved exceed 6 feet in height, provided they have only to be moved from one part of the grounds to another; but in the case of large plants that have to be brought long distances by railway, I should prefer to wait until the middle of September. When practicable, I prefer to prepare all the plants to be moved if they have stood in the same position more than four years, and if they exceed a height of 6 feet. The preparation should be made in the previous October, and should consist in digging a trench round the stem of the tree 2 feet deep and 1 foot wide. The distance that this trench must be from the tree will depend on its age and size; for a tree or evergreen shrub 8 feet high, the inner side of the trench should be 2 feet from the stem all round, and the width should be in proportion to the height. In digging out the trench all roots met with should be cut clean asunder; the trench may then be filled in again and left in that state. It will be found, when the time arrives for removing the tree thus operated on that every root cut asunder has broken out into a mass of fibres, and it is considered that these fibres are of far greater benefit to the tree after removal than the single root would have been if left undisturbed until the time of lifting. Experience proves this, for in practice I find that all trees or shrubs prepared in the way just described suffer much less than those not so treated; in fact, the percentage of living trees thus managed is far in advance of that of the other. The question as to the effect that a hard winter has on newly-planted trees is one that demands the serious attention of intending planters. It must be taken for granted, I think, that a shrub or tree only recently removed is not in so good a condition to withstand the severity of a long winter as one that had not been disturbed. In my own experience I have had trees removed during the late summer months that have stood to all appearance sound and healthy up to the time when severe frost has set in, then become brown in the foliage and ultimately die. This, however, to my mind does not to any serious extent injure the cause of summer planting, because it is only in the severest winters that trees thus suffer. On the contrary, it cannot be too well known that there is a decided gain by adopting summer planting. If a tree is moved towards the end of July, it will in great measure have completed its growth for the year, and if moved as soon as it has done that it will

get, other conditions being favourable, pretty well re-established before growth commences next season, and under ordinary circumstances it may be expected to make a fairly good growth the first year after removal; but in the case of autumn or spring planting it generally takes the whole of the next season to recover, and makes little or no growth. There is just one particular time in the summer eminently favourable to removal—I mean that period of the tree's first summer growth when it comes to a standstill. Many trees make two growths in a year, and the best time to move them is in the interval between the first and second growth. A little observation will enable anyone to detect when that time occurs, but as the habit of different trees varies, the selection of the time for

the A. mollis type I think it is best to purchase seedlings. Named varieties can be obtained at a higher rate. I would leave the selection to the dealer who supplied them, but a few good varieties of the Ghent type are Admiral de Ruyter (deep red), Altalacrensis (bright yellow), Carnes elegans (pink), Coccinea major (scarlet), Cupree splendens (pink and yellow), Elector (orange-scarlet), Sanguinea (crimson), Mirabilis (delicate pink), Horteri (yellow), Viscosa floribanda (white), and Decorata (pink).—J. D. E.

—The best varieties are Mollis, which have so many shades of colour; the Ghent type also possesses a great variety in colour; most of them are richly perfumed. Amens and pontica are early free-flowering kinds, with smaller flowers, but interesting and useful. The month of April is the best time to plant the bulk of sorts. It is needless trying to cultivate these Azaleas in the natural soil if there be the slightest trace of lime in it. Where the soil is peaty, or even sandy loam, they may be grown with success if leaf-soil be freely added. Where the soil is clay or heavy in character the whole of it should be removed to a depth of 18 inches, replacing it with peat and leaf-mould, two parts of the former to one of the latter. If the former can be easily obtained dispense with the leaf-mould entirely, but where peat is scarce the leaves may be used to economise the peat. After planting, if the weather be hot and dry, water should be supplied to the roots freely to induce the roots to push quickly into the new soil. A mulching of half-decayed leaves spread on the surface 3 inches thick checks the evaporation of moisture from the soil, and renders watering less necessary. Freshly-gathered cow-dung laid on the surface 2 inches thick directly the flowering season is past is a capital stimulant to plants that have somewhat exhausted the soil by free growth and continual flowering for, say, ten years.—S. P.

4053. — Quick-growing Ivies.—Rægneriana will grow quicker than any other variety, as much as 4 feet of growth being made in one season. The Irish Ivy follows next, and is perhaps the best of all for clinging to walls without assistance, or in fact but little, the vigorous growing young shoots do require occasional tacking to the wall. Any ordinary garden soil will grow Ivy. If it is poor in quality, add partly rotted manure freely. Ivy is a moisture-loving plant, and is much benefited by copious supplies of water during the spring and summer months when dry, and occasional doses of liquid manure is a great help to a speedy growth.—S. P.

—Two of the quickest growing Ivies are the ordinary Irish and Emerald Gem, a green as it is also called; but any of the stronger growing green-leaved kinds will make quick growth and the strongest of the variegated kinds. Emerald Gem is, however, very robust, and makes more rapid progress than any kind I know. It is a very fine variety, the leaves abundant, large, and rich glossy green in colour. Half the battle is, however, to get good plants, strong and healthy, and, if they are in pots, they may be planted at any season of the year, even in summer, provided that they are properly watered afterwards, and the soil is fairly good. Many seem to think that Ivies will grow anywhere, and stand any kind of treatment, but this is a mistake. If the position is so to say rough, an outbuilding or anything of that nature you wish to cover, then select the large-leaved Rægneriana, which will grow quickly, but it is rather too bold for a conspicuous position in the garden. Avoid the small-leaved variegated kinds, which are very liable to be coaxed into

OUR READERS' ILLUSTRATION: Retinospora aureo reticulata. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. Stafford, Wallcut, Ebbick.

removal may extend over three or four weeks, according to the character of the subjects to be operated upon. J.

4049.—Hardy Azaleas—These are truly beautiful plants for culture out-of-doors, and no garden should be without them. There is no doubt that a good light peat soil is best for all the hardy Azaleas; but it is an error to suppose that they cannot do without peat. Leaf-mould, mixed with light sandy loam, is excellent for them; if the loam is rather heavy add some coarse sand. Turf loam is best, and if this can be obtained, and leaf-mould to mix with it, peat may be dispensed with. There are two classes of them, the old hardy Ghent Azaleas, as they are called, and the Azalea Mollis, which have been introduced from Japan more recently.

respectable growth and require care. The best time to plant Ivies is the autumn or the spring, and these seasons should be selected unless the plants are in pots, then as previously mentioned it might be done even now. Ivies, as a rule, like a moderately shady spot, not exposed to keen winds and moisture, then they make surprising growth.—C. T.

—The Irish Ivy of very rapid growth, and a variety of it, called Emerald Gem, though less vigorous than the type, is in other respects superior to it. Ivy, like everything else, will grow best in good soil; and the ground should be trenched and improved, and some old manure or leaf-mould added. May be planted now if the plants are in pots.—E. H.

4018.—Propagation of the common Hawthorn.—The common Hawthorn of the hedgerows has to be raised from seed. The Haws are gathered when ripe, and when the outer coating decays the seeds may be sown. It is best to sow them in the early spring. Any quantity may be raised in this way. Any special varieties are propagated by grafting on the ordinary Hawthorn or White Thorn as a stock. It is in this way the nurseryman propagates the double-flowered red and white varieties, and also the single red variety. The only objection to raising the Hawthorn plants from seed is the length of time it takes to obtain plants large enough to form a hedge. They can be bought very cheap from the trade.—J. D. E.

—Probably the common Hawthorn could be propagated by a skilful propagator from cuttings, but the plant is difficult to strike. And the usual way to raise the common kinds from seeds, and graft or bud the choice varieties on the common sort.—E. H.

4051.—Rhododendrons and Azaleas in shrubberies.—Rhododendrons can be cut down and will start again much in the same way as most other shrubs will; but when they are planted in masses it is better to lift them at intervals of three or four years, and give the plants more space. They form such masses of roots in suitable soil that they may be lifted when of large size almost at any time without injury. I planted some a few years ago that had not been removed for fifteen years. The bushes had to be carted a few miles, and were out of the ground a week, but I did not lose one, and they grew away freely the following season.—J. D. E.

—The best time to cut these is immediately the flowers have faded and before the new growth is made. They may be cut during the winter, but so many of flowering shoots would then be sacrificed that it is better to wait and have the benefit of these. Both these shrubs are amenable to pruning, and if not done too freely in the case of old bushes they are improved, as new shoots push out and the old plants receive new vigour.—S. P.

—If you do not mind sacrificing the flowers the best time for cutting these plants back is, undoubtedly, the beginning of March, as then young growth will appear towards the end of summer, and when it is necessary to cut back into the old hard wood there is no better time than that which I have given. You may, however, have the benefit of the flowers next year and cut them back as soon as they go out of bloom. In that case not much young growth will be made until the following spring.—J. C. C.

—These may be pruned back when overgrown, but I should prefer doing this earlier in the season, say in March. If cut back now they would be some time before they broke out into growth, and the shoots made would not have time to ripen, and a severe winter would injure or probably kill them altogether if cut back much. But if the pruning was not of a severe character, and was limited to the shortening of certain straggling shoots it might be done now.—E. H.

4066.—Ivy growing on forest trees.—Certainly allowing ivy to grow on forest trees is detrimental to the latter; no matter how nice it looks, it should be cut away if the trees are valued more than the appearance of the Ivy. When tree-stems are covered with this creeper light and air is excluded from the bark so that it cannot perform its proper functions. There are, however, instances where it would be useless to cut away the Ivy with the idea of saving the trees. I allude to those already decaying, which is best known by the continuous falling of the branches. Over such trees a case the Ivy might be allowed to run, and make a fine

mental specimens of no mean beauty. Where the Ivy has not reached more than 12 feet up the stem and but young, no harm is being done; it is when the stems are, say, 4 inches in diameter that the harm follows.—S. P.

—There is a diversity of opinion amongst practical men as to whether Ivy does or does not injure the growth of trees of any kind when it climbs them. My experience is that in the case of young trees it does check their growth; but after a tree has reached a height of 40 feet or 50 feet, I think the injury is not great if they are kept free from Ivy until that time. According to my observation the Ash and Birch trees suffer more than any others.—J. C. C.

—Ivy should not be allowed to grow on forest trees cultivated for timber. In private grounds, where ornament is more thought of than the value of the timber or even the life of the tree, Ivy may add its picturesque beauty to the scene.—E. H.

4094.—A Privet hedge.—Cut down a Privet-hedge to thickness in March. You might fill in with young plants, which are better than cuttings. They are cheap enough.—E. H.

THE SKIMMIAS.

THE only species of this genus—there are but four altogether—worth cultivating are *S. japonica* and *S. Fortunei*. The former, as its name implies, is Japanese; the latter is a native of China.

First of all, I must state that there has been very much confusion between these two species, and to Dr. M. T. Masters belongs the credit of having cleared away the mystery which surrounded them. The plant universally known in gardens as *S. japonica* is really not Japanese at all, but a native of China, whence it was introduced into the nursery of Standish and Noble in 1849. Mr. Fortune—the discoverer of the species—met with it in 1848 in a garden at Shanghai, the nurseryman from whom he obtained it informing him that the plant was brought from a high mountain in the interior called Wang Shang. Of all the plants Fortune sent to the nursery above mentioned only one reached England alive, and this identical plant was exhibited at the Horticultural Society's rooms, 21, Regent-street, on October 23rd, 1852, "when the Knightian medal was awarded it, and the plant, in popular parlance, made a great sensation." The proper name of the species is *Skimmia Fortunei*. The true *S. japonica* is a Japanese plant, and did not find its way into British gardens for some years after *S. Fortunei*. Like that species, it was introduced by Fortune. Unlike *S. Fortunei*, this is dioecious—that is to say, one plant bears female flowers and the other male ones. Both sexes have received specific names, and mere forms of both have been described specifically in horticultural periodicals. *S. fragrans*, for instance, is simply the male plant of the true *S. japonica*. The first plant of *S. japonica* which flowered in this country was named *S. oblata* by the late Mr. Thomas Moore in 1864. As, however, Dr. M. T. Masters has clearly shown that this plant was exactly identical with the one named *S. japonica* by Thunberg, that name had to be transferred to it, and the one named *S. japonica* in gardens was called *S. Fortunei*.

The *Skimmias* thrive under very varied conditions as regards soil, &c. I have seen them thrive splendidly in strong clay and also in poor sandy soil and peat. The true *S. japonica* is one of the very best town Evergreens we possess. To sum up, the real facts as to the names, &c., of the *Skimmias* above mentioned are as follows:—

S. japonica of Thunberg is the name to keep up. It is a native of Japan. *S. oblata* of T. Moore is the female plant, and *S. fragrans* is the male plant of the same species. Other forms are *S. Foremanii*, *S. Rogersii*, *S. oblata ovata*, *S. fragrantissima*, and *S. oblata Veitchii*. In order to produce such beautifully berried species as those grown by Mr. Foreman, of Dalkeith, and Mr. Rogers, of Southampton, it will be necessary to plant specimens of the two sexes in proximity.

S. Fortunei of Masters is a native of China. *S. japonica* of gardens is identical with this. *S. rubella* is a seedling form. *S. japonica argentea* is a seedling or sport, only differing from the type in having the leaves bordered with white. *S. Fortunei* is a much dwarfier grower than *S. japonica*, and does well as a pot plant for window-decoration, &c.

4080.—Marie Louise Violets.—No heat whatever is necessary to grow Double Violets really well, nothing is better than ordinary garden frames, rendered secure from frost by enclosing the sides with a thick coating of leaves or litter. The lights should be covered with mats or other protecting material sufficient to keep out any frost. If provision can be made for this there is no fear need be entertained about success. The chief point in growing Double Violets of White Marie Louise is the best kind is to have thoroughly well-prepared roots by the middle of September, which is the best time for placing them in the frames. It is useless to expect good flowers and a quantity of them from poor weakly plants. It is difficult to advise at what distances in the frame the plants should be placed, as so much depends upon their size. The best guide is to have the leaves of one plant just touching those of its neighbour. An ordinary frame of two lights about 6 feet by 8 feet will accommodate about six dozen plants. This will give some idea of the number of plants to prepare during the summer. The end of April is a suitable time to set about preparing a stock of plants. The roots which flowered last season in frames should be pulled in pieces, planting them in rows in well-worked, not highly manured land 10 inches apart. During dry weather supply them freely with water and keep them free from runners and weeds. The best winter quarters for the frame is a sunny position sheltered from north and east winds. Place the frame on two bricks at each corner to raise it above the soil, which is a preventive against the rotting of the frame. At the bottom of the frame I place a layer of faggots or old Pea-stalks for a twofold object—viz., raising the plants near to the glass, and permitting of thorough drainage, as I find the development of the bloom is retarded if the roots are waterlogged. On the wood a thin layer of stable-litter is placed to prevent the soil running among the faggots. Over the straw a layer of last year's leaves is placed, into this the roots of the Violets find their way, they being especially partial to decayed leaves. The soil we use is mainly composed of roadside refuse, with which is mixed a quantity of grit that assists in keeping the whole porous. To this we liberally add decayed leaves, with the addition of a small quantity of horse-manure partly decayed. This compost is about 9 inches thick. If the soil in the garden is naturally inclined to be sandy add the horse-manure and decayed leaves to it simply. The plants are then lifted with a good ball of soil and roots attached, and planted in the frame; the soil is pressed firmly about the roots. When the plants are placed in the frame the leaves are quite at the top of the sides of the frame. In a short time the soil settles down, so that by the time the lights are placed on the plants are within 2 inches of the glass. They should receive a good soaking of water which settles the soil about them. Do not place the lights over the plants until there is danger of frost or continuous rain, even then tilt them at the back to admit air to the plants. The roots make progress but not the leaves, which is what is required if many new leaves are made before the April following, the crop of flowers is a thin one. Although a few degrees of frost will not injure the Violets when the lights are on, it is not wise to have the leaves touched by it. Abundance of air should be given at all times when the thermometer out-of-doors stands above 35 degs. Anything approaching to scolding the plants is detrimental to their welfare.—S. P.

Lilium candidum.—In reference to the tendency of this Lily to fall after it has made considerable growth, no doubt, as with many other things, remedies may not equally apply in all gardens. With regard to the shallow planting of which I spoke before, I think there can be no doubt as to its being the proper thing to do where the soil is stiff, and it may further interest readers to know something of the results of shallow planting, because many of us have seemingly grown the plant well up to the stage when the buds are half developed, when they have gone off. All this seems to point to a drier state as being desirable for the bulb. There cannot, of course, be the least cause for fear as regards the action of frost on the bulbs close to the surface, as this causes no injury whatever to bulbs that are well established.—

HOUSE & WINDOW GARDENING.

ARRANGING CUT FLOWERS.

At several of the exhibitions of the Royal Horticultural and Botanic Societies in recent years various groups of cut flowers, arranged on a new principle, have attracted much attention. These groups are in the form of a cone or pyramid, the only evidence of a containing vessel being the edges of a flat plate, which appear here and there where not concealed by the border leaves of the group. It is clear that, except by the use of soft plastic clay, it would not be possible to produce these effects in any ordinary vessel. But as clay is not without its inconveniences, a special kind of vessel has been invented by Mr. March in the form of a solid dome or hemisphere, in which are sunk numerous tubular orifices, upright in the centre and gradually

appropriately mixed with Forget-me-nots, Rushes, Arrowhead (see illustration), and other leaves of water plants, while stove and greenhouse flowers are appropriately treated with foliage which thrives in a warm temperature. The smaller domes are best adapted to table decoration, as the flowers do not rise to an inconvenient height, but some of the tubular holders are made of large size for the display of massive subjects, such as Sunflowers, Peonies, Hollyhocks, Hydrangeas, branches of flowering trees and shrubs, large Ferns, Rushees, and Pampas Grass. These are not easily arranged in ordinary vases, but placed in the wide and deep tubes of such flower-stands, they form striking decorative objects, having all the better effect for irregularity of outline. The main and commendable idea of the invention is to avoid overcrowding, and to give to each spray of leaf or flower its separate and distinct meaning.

Water lilies and other flowers arranged in a tubular flower-stand.

diverging outwards till they approach the horizontal. This vessel rests on a separate plate of glass, terra-cotta, &c., of wide diameter and nearly flat, but capable of holding sufficient water to refresh the border leaves of the group, which form a distinct feature in this kind of decoration. The plate is sometimes placed on a flat circle of dark Utrecht velvet. Flowers and leaves inserted in the tubes take the exact inclination desired, and the design can thus, as it were, be sketched out and studied as the work proceeds. This system gives the power of forming artistic groups, in which characteristic foliage takes a far greater part than is usually assigned to it in floral arrangements. In the case of wild flowers, for instance, Primroses, Bluebells, Digtalls, Campanulas, and others, according to season, are intermingled with Grasses, Ferns, Bramble, and other beautiful foliage which can be found in every hedge-row. For an aquatic group, Water lilies are

Hydrangeas in small pots.—Few flowers are more durable than the Hydrangea, for coming in as they do just when heat is so trying to ordinary flowering plants they fill a gap that it would be hard to find a substitute for. To get good plants in 5-inch or 6-inch pots, the cuttings should be struck now, taking off the tops of shoots which have not flowered, and inserting them singly in very small pots. They strike well in handlights or cold frames, kept close until rooted, and then potted into their flowering pots, and grown on in cold frames, merely protecting from frost in very severe weather. As soon as they start into growth in spring, and the flower-heads are visible, give manure-water twice a week.—J. O. H.

Achillea rupestris proves to be more than ordinarily useful, as it is setting for a second complete set of bloom. Possibly this may have been influenced by the specimen having had all its strongly growing heads cut off in March as cuttings. Still, the buds are showing on younger stems that have formed since that date.

FRUIT.

NEW WOOD ON OLD FRUIT-TREES.

THE Vine is perhaps the most familiar example of fruitfulness—in fact, it has grown into a proverb to be as fruitful as a Vine; but there is a great deal of difference between the fruit grown on old wood and that produced on young wood even in Vines, and the same holds good with the majority of fruits. Now, taking Vines first. We are all averse to rooting up those that are producing fruit in anything like a crop; but, as a rule, old, hard canes and knotty spurs will produce even more bunches than the Vine can support, but they certainly become smaller as the Vine attains age, not apparently from exhaustion of the Vine, but from hardness of the wood; and the question how to rejuvenate one's Vines so as to get a new head of bearing wood without loss of a crop in any one year is a problem that many would like to solve. Yet it is a very simple process, for, supposing you have a dozen main-stems in your viney that have been closely spurred in for many years, I would select half-a-dozen of the most promising shoots at the base of each alternate Vine, and let them grow entirely unchecked during the whole season, merely pinching out any lateral growths, and at the end of the year you will have half-a-dozen finely-ripened young canes. Then at the winter pruning cut out half the old rods and shorten the young rods at least half way down the rafter; you will get as many Grapes and much finer bunches from the young wood; and the following year you may replace the other old rods in the same manner; in fact, there should be a constant change of rods, taking out and replacing a few every year. Wall fruit-trees, of which Paachea, Nectarines, and Morello Cherries are familiar examples, are usually trained on what is called the fan system, and bear their fruit almost exclusively on young wood of the preceding year's growth, the requisite quantity of young shoots being selected at the summer pruning, and either tied in loosely or nailed to the wall; and at the winter pruning the older shoots that have borne the crop of the preceding year are cut away to make room, and very seldom is there a failure of crop on trees treated in this way. But with Pears, Plums, Apricots, and Cherries of the dessert kinds, whether trained on walls or trellises, and pruned on the short spur system, it will be found that after a few years the old spurs get so hard and long that the crop is greatly reduced, unless means are taken to introduce young wood. I find it a good plan to cut any very long spurs right off at the winter pruning, and fresh shoots, that can be shortened to form new spurs, will push out close to the base of the old spur, and from the light and air lot into the centre of the tree young shoots, that will eventually form main-bearing branches, can be trained in, and some of the older ones cut right away at the winter pruning—in fact, some kinds of Pears, as, for example, the Jargonelle, will not bear fruit at all except on the young wood. To sum up, no matter what the form of training is, a proportion of young wood should be laid in every summer, and an equal quantity of the old cut away—at least, such is my experience, and I grow fruit-trees solely for the fruit they produce; and although I have a decided liking for old trees, I wish to see them well furnished with vigorous young wood, fruitful from base to summit.

J. GROOM, Gosport.

4068.—A Vine question.—It is certainly a very unusual occurrence for the Vine berries to shrivel up all at once "in a few minutes." When anything is wrong with the roots Vines are liable to "shank"—that is, the fresh stalks of the berries decay, rather suddenly sometimes, and as a result the berries shrink up and are worthless. This may be a case of shanking—an unusually bad case—and there is no cure for it except seeing that the Vine-roots are placed near the surface. There is a great deal in the character of the soil in which the Vines are planted. Vines do not succeed in all soils alike. They do not succeed when the loam contains no lime. If mortar or plaster-rubbish cannot be obtained to mix with the soil I would use quicklime, at the rate of a bushel to a cart-load of soil. My Vine borders were well made and the soil had more far than back in June proportion added

to it; but after some years' cropping, shanking began; and heavy dressings of manure made no difference. I gave a good dressing of powdered bones one year and the shanking was not nearly so bad; another good dressing was given this year, and the roots came freely up after the powdered bones, and I have not seen a shanked berry in three large vineries. I would try forking in a good dressing of powdered bones.—J. D. E.

The Vines appear to be affected with a disease that is known as "shanking." Directly the berries commence to colour the stalk turns black, the berries shrivel, and eventually fall off. Instead of being composed, as they ought to be, of flesh and saccharine, they are a sour mass of water only. The principal cause of shanking is overcropping, although many errors in culture will cause the crop to be so affected, such as withholding moisture from the roots too long, or having the roots too deep in the border, so that they are stagnated by too much moisture, owing to a lack of drainage. Again, the manipulation of the shoots will sometimes cause shanking. If the laterals are allowed to run almost wild, say, make shoots all over the house 2 feet or 3 feet long, and then to suddenly remove them all from the Vines, this treatment would give a check to the Vines, and most likely result in shanking. Vines growing in a new border, but recently made, should be cropped lightly the first year—say, a 12-foot rod ought not to carry more than 10 lb. of Grapes the first year. This may appear to be a small quantity, but it is far better for the Vines to be allowed to gather strength by making more roots and developing better foliage for the first year after interfering with the roots. I am not in favour of pulling out Vines if they are under twenty years old, or even thirty. Care and judicious treatment will often render old Vines more profitable than young ones for several years—at any rate, during the time the young ones are growing.—S. P.

The information you send points conclusively, to my mind, that your failure is the result of scalding by an overheated atmosphere, owing to insufficient ventilation, with too much atmospheric moisture. You have either neglected to open the ventilators sufficiently to allow the heated air to escape, or sufficient space is not provided in the form of ventilators to keep the temperature down to a safe point. This is a point that no stranger can decide, and as it is a serious case I advise you to seek the advice of a skilful gardener on the spot, who will be able in a few minutes to tell you if my surmise is right. I do not advise you to root out the Vines until you traced the cause. It would have been better if you had sent an outline of your management, and the distance the Vines are from the glass. You had better ascertain the temperature of your house on a hot day by placing a thermometer under the Vines and within 2 feet of the centre ventilator at the top. If it is over 90 degs. at that point it is too much.—J. C. C.

The disease affecting the Orapes appears to be what is termed scalding, and generally takes place just as the Orapes have about finished stoning. The cause generally is want of sufficient ventilation, especially early in the morning. Certain varieties are more subject to it than others. A thin shade placed over the roof will check it. In the meantime give more air. A very small shink of night ventilation would stop it if begun in time, or if the house was opened ever so little as soon as the sun struck the roof, this would answer the same purpose. A little more foliage might be left on the Vine if there is room without overcrowding.—E. H.

4069.—Management of an orchard.

The first thing to do is to find out what kind of fruit and vegetables sells the best locally. The soil appears to be of the right kind to grow any fruit or vegetables. The first thing to do is to plough the land several times between the existing rows of trees, so as to have it thoroughly clear by the middle of October. If it is possible to stir it 10 inches or 1 foot deep by the aid of a subsoil plough some expense will be saved when the time comes to plant the trees, as so much spade labour will not be necessary as if nothing were done at the soil between now and then. So much depends upon the locality and its requirements that it is difficult to give a

selection of varieties, or even kinds of fruit best for the purpose; but no mistake can be made in planting a goodly number of early kitchen and dessert Apples, such sorts as Lord Grosvenor, Echlinville, Warner's King, Stirling Castle, and Lord Suffield, if this succeeds in the neighbourhood. Of dessert, such showy sorts as Lady Sudeley, Devonshire Quarrendon, and Worcester Pearmain ought not to be omitted. Late varieties like Lane's Prince Albert, Alfriston, and Newton Wonder; and for dessert Cox's Orange Pippin, and King of the Pippins for a late supply ought not to be omitted. It is a mistake to plant a lot of sorts, far better plant many trees of one kind in preference. I should advise that they all be bushes, not formally-trained pyramids, which are useless as fruit producers in a short time; besides, too much labour is required to train them to preserve the form. I do not advise that cheap trees be bought at risk. Far better to purchase good trees from well-known firms at, say, £10 per hundred, than others at half the price. One row of bush trees could be planted between the existing rows. A space not less than 10 feet should be allowed between the trees in the rows. Between the newly-planted and the older trees, one or two rows of Gooseberry bushes, Currants, or even Raspberries should be planted to fully utilise the space. Even then, while the trees are young, a crop of vegetables, such as Cauliflowers, Broccoli, Brussels Sprouts, Carrots, or Onions, can be taken off the intermediate space. Or, again, in the place of vegetables, Single Violets would succeed, and these pay remarkably well in some localities. Narcissus, both double and single, especially the Pheasant-eye type, would grow well in soil of the character described. So much depends upon the means at command to purchase stock to start with. The great advantage in having so much variety is that hardly ever in there a season when all things fail, owing to unfavourable weather or other causes. Filberts would answer really well in such a soil; Kent Cobs, too, are in great demand as a rule. Damsons and Plums sell well at times, except when there is a glut. The Fairleigh, or Chester, is perhaps the best kind of the former, and Victoria or Rivers' Early Prolific, the best Plums. Of Peers I will say but little; if they grow and crop freely, by all means plant the best sorts, such as Williams' Bon Chrétien, Pimaston Duchess, Louise Bonne de Jersey, and Doyenné du Comtes. In all cases these should be bush-grown trees, and so should the Plums, but the Damsons are best as standards. Potatoes sometimes pay to grow; they certainly are good for the purpose of cleaning the ground where at all weedy. As for their culture, it is necessary to well stir it both in planting, earthing them up, and again at digging time.—S. P.

In the first place you have to consider whether it is possible to secure a greater profit by stocking and cultivating the ground between the trees than you now receive as a rental for the pasture. Of course I do not say whether you will be able to do so or not, but from the information you send you appear to have everything in your favour of making a greater profit. If it was my case I should plant bush-trees of Apples and Cherries chiefly over one half of the space, and Raspberries and Strawberries to the other half; you may plant a line of bush Apple-trees between the standards. The sorts may be Echlinville Seedling, Lord Grosvenor, Cox's Orange Pippin, Lord Suffield, and Celloni. The trees should be on the Crab-stock and planted 8 feet apart. You may also plant two trees between the others in the same line. There is room for three rows of Raspberries at 4 feet apart between the established trees, and double that number of Strawberries.—J. C. C.

If the ground is trenched up and manured, Gooseberries, Red Currants, and Raspberries would probably pay the best. The expense of preparing the ground and planting the bushes would have to be considered, but there is no doubt on such land it would pay.—E. H.

4054.—Packing Peaches and Grapes.

Peaches travel best when packed in boxes just large enough to hold one or two dozen in a single layer. Lay some soft material in the bottom of the box, such as paper shavings, letting it come up the sides also. Dry Moss that has been well beaten to clear out dirt and dust will do, but there is nothing to equal paper shavings. On this place a sheet of cotton wadding, and the bed

is ready for the Peaches. Wrap each Peach in a piece of tissue paper, and then place a strip of wadding round several folds to take off the pressure where the fruits meet. Pack tightly, and when the box is full lay another sheet of wadding and fill up the box with paper shavings or some substitute. Place on the lid and tie it (not oiled) down. Grapes are best packed in handled baskets that will hold from 8 lb. to 12 lb. Place a sheet of wadding in the bottom, paper shavings or anything soft and elastic will do. On this place a lining of paper. Tilt the basket a little to one end and begin to lay the bunches in the lowest end till the basket is quite full, so that they cannot shake about. It is the shaking about which does the mischief. All fruits and flowers travel best when packed tight enough to prevent moving. Cover the top of the basket with paper, and lace string over the top. Sometimes two pliable Hazel sticks are used with the ends thrust in the basket at opposite sides to support the paper, but if a little wood is cut with the bunches of Grapes these form a protection to the bunches; and when the string is laced tightly over the top of the basket it is seldom any harm is done, unless the baskets are rung about by the railway-porters, and this happens sometimes.—E. H.

4002.—Walnut-tree dropping its

Nuts.—I would surmise that the cause of the Nuts dropping is the excessive drought. It is unusual for them to drop before their time, and not to be accounted for in any other way. In this district, not only the fruit, but the leaves also, are dropping from the trees in some instances. I fear we lose many of our Apples and Pears on trees where we have been unable to water them. Small fruits are shrinking up on the bushes. In the case of the Walnut-tree, as it has occurred before in previous years there may be some local cause to account for it.—J. D. E.

It is not a matter for surprise that the tree should drop a quantity of its Nuts in such weather as we have had lately, and especially when growing in such a dry position as that described. Abundant watering and a coat of manure will be found the only means of stopping the loss, though if the tree is already overloaded it will be all the better for being relieved of part of its crop. In future you should apply a good mulch of long manure or something of the kind as soon as the hot weather sets in, or rather just before.—B. C. R.

Your trouble is easily explained. Walnut-trees are raised from seed, and yours is an inferior variety, and not worth the space it occupies. This fruit-dropping is an inherent character for which there is no remedy but to replace the tree with a better variety. Certainly dryness at the root would not cause the Nuts to drop in a good deep soil.—J. C. C.

I have seen the same thing happen with trees out of condition, or in a very dry season. Walnut-trees suffered a good deal this year from spring frosts, and imperfect fertilisation may have had something to do with the Nuts falling.—E. H.

Strawberries after fruiting.—

This has been far and away the most trying season for outdoor Strawberries I ever remember. From the time the plants came into growth there has been no interval of rest, and the fruit has had to ripen in the influence of fierce sunshine and a parching atmosphere. Even where plants have been well supplied with water they have, I find, suffered considerably. If rain in abundance does not come watering should be continued after the fruit is gathered, or the crowns will be weak, and the crop poor next year. A little attention in this way will be sure to have its reward.—BYFLEET.

Picrorrhiza Kurrooa.—

I believe this curious plant, which is, moreover, quite hardy and possesses a very neat habit, is now growing in many more gardens than it used to be a few years ago, and what I chiefly wish to say is that I have grown it five or six years in almost every imaginable way out-of-doors, and I have not yet seen a single bit of bloom. Has any reader flowered it in the open garden? and if so, under what condition as to soil, position, locality, &c.? It may say something for our patience to go on longer with a non-flowering plant, but it would not be much use unless someone has hit upon the way to get flowers. I am told the flowers are a fine blue. Who will tell us how to get them?—J.

OUTDOOR PLANTS.

ANTHERICUMS.

The several species of which this genus is composed are very beautiful and attractive, and therefore deserving a place in all good collections of herbaceous plants. In those instances where they are grown, too frequently these graceful plants are only represented by isolated and solitary examples, and such as these convey very inadequately any idea of the charm which they possess when planted in large groups. What these plants most thoroughly enjoy and what they should receive from all who would grow them to perfection is a good depth of rich loamy soil, rather sandy. Always plant them in a spot where they may remain to become established, for few plants are more impatient of frequent interference than these. But where allowed a few years to establish themselves fully they provide a most pleasing feature. By the above remark I do not infer that it will take years before they reach flowering size; on the contrary, you may get a flower-spike the year after planting, but it will assuredly be weak, and but feebly represent the

some kinds, particularly *A. Liliastrum* and *A. L. majus*, have a peculiar way of multiplication, and of heaping and clinging to each other, censed, in reality, by the roots taking a horizontal course and becoming entangled with each other. There will be many crowns, all of which will prove intact with roots if all the soil be washed away in water, thus leaving them bare. When free from all soil the plants are easily disentangled with the finger and thumb end an occasional shaking, a very simple and easy way, and when carefully done hardly a root will be lost. On the other hand, the knife should never be used in dividing these plants; indeed, it can never be used in the case of established pieces without much sacrifice. Another

MODE OF INCREASE is by seeds, which may be sown when ripe or kept till the winter ensuing in some cool, dry place. Well ripened seeds germinate quite freely, but are very slow, and I do not find that sowing the seeds directly they are gathered forwards their germination in the slightest degree; therefore they may be kept and sown at leisure during autumn or winter. Owing to their slow germination, therefore, it is not safe to discard boxes or pans of seeds of such things under two years, though,

very pretty graceful species, and assumes a more clustered habit of growth, from which issue many flower-spikes and abundance of starry blossoms of the purest white. J.

4063—**Alpine Auriculæ**—Black mud from the bottom of a pond would be nnsafe material to use as a mulch for Auriculæ. The best materials to place around the plants are good loam and decayed manure, mixed together in equal portions. These should be used in the spring as soon as the plants show signs of growth. They need no other attention at any time, except to keep them free from weeds and to remove decaying leaves from the plants which are nightly. The plants should flower strongly next year. Spanish Irises are better lifted and replanted annually. If left in the ground and the soil is suitable they will grow and flower two and three years in succession, but they do better the other way.—J. D. B.

— It would be best to leave the plants alone, as doubtless, from your description, they will bloom well in good time if you have patience. The Spanish Iris is a bulb that hates disturbance, and to be constantly lifting them is one way to court failure. Here are a few hints as regards their culture. The position must be neither too damp nor too dry, and the soil sandy, light, and moderately rich, some amount of well rotted manure or leaf-mould being incorporated with it. Give a rather sheltered spot, not too shady, as the flowers are always happier when not exposed to the full force of the wind. It makes growth early, and the bulbs must get well dried, although after the winter genial rains assist much the slender growth. As yours were only planted, as far as I can judge, last year, by all means leave them alone. Perhaps their unsatisfactory condition may be accounted for by an unsuitable position in which they are placed.—C. T.

4065.—**Lilies and Irises.**—With the soil you mention I should recommend you to confine yourself to the rhizome-rooted form of Iris, especially the varieties of the German Iris, and to such hardy, strong-growing Lilies as *L. ligurium*, *candidum*, *lanceolatum*, and the common Turk's-cap Lily.—A. G. BURMAN.

— The most reliable Lilies are *candidum*, *davuriense*, *ligurium* (double and single varieties), *croceum*, and *bulbiferum*. These are hardy and vigorous thriving, best in loam of a well drained not too heavy a nature. A clayey loam is not very favourable for Lilies holding so much moisture in winter that the bulbs are apt to suffer. It ought to be lightened by the addition of river-sand, leaf-mould, or anything that will render it more porous. By incorporating some peat with it, it would be possible to grow the varieties of *speciosum* and *auratum*. The English and Spanish Irises ought to do very well, also the beautiful varieties of *Germanica*, *pallida*, *neglecta*, and *variegata*. These are very showy, and when they come to good-sized specimens produce quantities of bloom. The Spanish and English Irises are better for lifting in autumn, replanting in early spring. I should also try a few plants of the lovely Japanese Flag Irises (*I. Kämpferi*). These are lovers of moisture, and require a soaking of water occasionally in hot, dry weather.—J. C. Byfleet.

4056—**Creepers for a cemented wall.**

—There is no creeper that will cling to a cemented wall, or, indeed, any other wall, without nailing beside *Ampelopsis Veitchii* and Ivy. Even the latter requires some attention to fasten the leading shoots to the wall; oftentimes when the growth is free it refuses to cling for a time. If an evergreen creeper is absolutely necessary I should advise the planting of Irish Ivy. By fixing here and there a wire to the wall in an horizontal position the Ivy is easily kept to the wall by fastening it behind the wire. Cuttings root freely in the autumn if cut into lengths of 10 inches and inserted in sandy soil, making them quite fast at the base, afterwards mulching the ground between the rows with leaf-soil, vegetable refuse, or anything that will tend to ward off frost. Although this will not kill the Ivy it lifts the soil and loosens the cuttings at their base, in which state they cannot possibly make roots. If the cuttings are put in about the middle of October and allowed to remain until the following April twelvemonths, they will be stocky well-rooted plants fit to put out where required. The first week in March is a

A *Rodriguezia* growing in a hanging-basket. (See page 262)

same plant when fully established. One little item, though a very important one, concerning Anthericums is that they should always be planted or transplanted while dormant, and where this operation is deferred till growth has commenced, it can scarcely be completed without loss of the central crown or growth. It is also a good plan, having dug the ground to a depth of 2 feet or more and thoroughly enriched it with manure, to remove some 4 inches of the surface-soil so as to admit of the roots being laid out in their natural manner of growth, instead of being huddled together in a small hole. Place the crowns about 9 inches apart each way, or nearer if the desire is for immediate effect, and then sprinkle half an inch of silver sand in and among their roots prior to returning the surface-soil. Thus planted, they will be safe for a dozen years or more, and annually constitute one of the most beautiful objects in the garden. But instead of allowing them to remain so long undisturbed, it may be desired to establish other groups in different spots in the garden, and for this purpose it will be necessary to lift and divide the original group. When the plants are lifted after having remained a few years in one spot, it will be seen when all the soil is removed that

as a rule, they show freely through the soil in about eighteen months. For these reasons it is always best when the seeds are sown to cover them with a board or slate, everything in fact that will tend to keep the soil uniformly moist over a long period, and at the same time prevent weeds springing up and likewise check interference by birds or other intruders. Such a covering, too, dispenses with frequent watering, by which means the seeds are often laid bare and such like, a decided drawback with choice or rare species, and where only thinly covered with soil. As with established plants so with the young seedlings, always transplant them when dormant, but in the case of these Anthericums they will not need transplanting till a full year's growth has been completed. The kinds in general cultivation are not numerous, and the best and most decorative of these are *A. Liliastrum* (the St. Bruno's Lily), *A. Liliastrum majus*, a giant form of the preceding. This is by far the most beautiful of all, and a plant which should figure in quantity in every garden, the fine spikes of snowy bell-shaped blossoms being exquisite in the extreme. These two may easily be distinguished by the clear white fleshy roots, which are somewhat like *A. Lillago* (the St. Bernard's Lily) is a

good time to sow the Variegated Hop and Canary Creeper in a gentle warmth, removing them to cool quarters directly the plants are above the soil, and grow them on stocks, so that when put out in their permanent quarters the growth will be free and uninterrupted.—S. P.

—There are no creepers, except Vetch's Virginian Creeper and the small-leaved or Wild Ivy, that will cling to a cemented or any wall without being nailed. The Japanese Hop and Canary Creeper should be sown in spring in a gentle warmth; nothing will be gained by sowing them in the autumn. March is the best month.—B. C. R.

4065—Treatment of Pancreatium.—Pancreatium illyricum is not hardy in all parts of England, especially away from the south and west. Perhaps this is the cause of your bulbs refusing to grow. If your friend's garden is situated not far away from your own, and her plant flourishes, this may be owing to a difference of soil. If that in her garden is sandy and yours the reverse that would account for the difference. If the latter is the case I should advise you to choose the most sunny spot in your border. Take out the soil 2 feet deep and 18 inches in diameter; break up the soil at the bottom of the hole, and place thereon 11 inches of broken bricks, clinkers, or stones, as a means of causing surplus water to drain quickly away from the bulbs during the winter. Over the drainage lay some freshly-gathered leaves to prevent the drainage becoming choked. Fill up the space with soil of a light character, such as leaf-mould, old potting-soil, road grit, and sand, and plant the bulbs early in March 4 inches deep, finishing off with a mulching of partly-decayed leaves, repeating this latter every autumn as a protection against frost. Should the weather be very dry during the time growth is being made give the plants occasional soakings of water. The Carnations should be potted in a compost of loam three parts to one of partly-decayed horse-mannure or leaf-soil, adding sufficient sand to keep the whole porous. Do not give the roots too much pot-room; an inch all round will suffice. Stand the plants in a sunny spot, and water them carefully.—S. P.

4055—Box edging.—The kind of Box used for edgings to paths is not the same kind as that forming a bush—the former is a dwarf-growing kind named suffruticosa, belonging to the sempervirens type. The common green variety growing as a bush is the type to which that generally used for edging is descended. You must procure some of the right kind; one yard that has served as an edging for several years will divide sufficiently to plant three yards. The months of March and April is the best time to plant. The ground should be thoroughly dug and levelled by the aid of a square-edge and spirit level to determine the level of the path on both sides at each end. The intermediate levels are best obtained with three T-squares, commonly called horning-rods. One of these is stood on the level peg at each end of the path, which has been put in with the aid of the square-edge and level previously named. The third rod is used to get the various intermediate levels, by sighting from the end. That in the centre should be raised, or lowered as necessary, until it comes into line with that at each end. When the soil is made quite level and firm, a trench 6 inches deep should be cut in a perpendicular manner, chopping the soil towards the path with a spade. The Box should then be pulled into pieces; every hit with roots attached will grow. Cut off the tips of the shoots to make the edge look square; this facilitates the planting and makes neater work. With the right knee on the ground and the left foot in the trench, the Box can be quickly laid in order; the left hand hold it in position, while with the right it is placed there and soil is pulled over the roots also. The foot in the trench makes it firm as the work progresses. The trench is filled with soil and trodden firmly—in fact, it cannot be made too firm. The keeping of the ground firm about the roots renders the Box always dwarf. If the tops were evenly cut before planting no clipping will be necessary the first year and but little the next.—S. P.

—The Box-trees are of a different variety than that used as an edging to walks. It is no use planting the edging with cuttings. An edging of dwarf Box that has been down for some years can be taken up and the piece divided. One yard of old will plant 3 yards of new.—J. D. E.

—The dwarf Box, usually employed for edging, is quite distinct from the ordinary tree or bush variety, and the best way will be to purchase some stock of the form, and divide and plant it by and-by. If you know any other, take cuttings of the bush in October, and put them out next year when suitably rooted.—B. C. R.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *Gardening* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who refer would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4086.—Ailing Fuchsias.—Some of my Fuchsias are ailing. The undersides of the leaves so rusty looking. Is it red-spider? If so, what is the remedy?—C. N. P.

4087.—Striking cuttings of ebrube.—Will any person kindly let me know when is the best time to strike cuttings of Escallonia and Deutzia? Also please name a few good shrubs that can be struck from cuttings?—DAVID.

4088.—Fuchsias for a trellis.—Will someone kindly give me the names of six best climbing Fuchsias for growing on a trellis in a conservatory facing west, which gets the sun from ten to six in summer? Answer to this will oblige.—A CONSTANT READER.

4089.—Sweet Williams, &c.—I have a very good Sweet William and a very good Canterbury Bell now in flower. Is there any way of reproducing these plants by cuttings or any other way, so as to be certain of getting flowers of the same colour next year? If so, how is it to be done?—A. T.

4090.—Unhealthy Cucumbers.—I should be very glad if someone would tell me the cause of my Cucumbers, leaves turning brown, with dark spots about the middle, and the edges turn up and the fruit gets yellow? They are in a frame on a hot-bed. Been planted about two months. Also what time to give them air to the morning?—SHERKID.

4091.—Orchard (14 acres) destroyed by insects, caterpillars, &c.—Will some experienced writer inform me what is the best dressing to give trees in September, October, and November to kill insects, caterpillars, "American Blight," &c.? Trees planted forty years; pasture land under same. I am under agreement not to destroy trees.—REAR.

4092.—Tomatoes dropping their buds.—My Tomato plants are strong and send plenty of flowers, which set and then drop off at the first joint. I have them growing both in borders and in pots. I have three sorts—18th Gem, Conference, and Vick Oriferno—but they are all alike. I have syringed a few times, and they seem a little better. They got the sun all day.—J. R.

4093.—Early Roses.—I shall be glad if someone will kindly inform me which classes of Roses are likely to produce the earliest blooms in this district, whether *Tea* or *H. Perpetua*? And perhaps someone can give me the names of about a dozen of the earliest, suitable for button-holes and for planting out-of-doors? My garden is well sheltered on all sides from cold winds, and the bed I propose to replant has an eastern aspect, with sun on it till middle of afternoon.—ROSE, E. Yorks.

4094.—The culture of Stephanotis.—Can any reader of *GARDENING* inform me on the following subjects? I want to grow the above beautiful plant for market. Can any kind of friend assist me? How to propagate *Stephanotis*, and its after culture? The best place to rear the plants to begin with, and probable cost per hundred? After being thirty years absent to different parts of the world I have settled down to my old calling. Need I say I feel somewhat perplexed?—SOLMAN.

4095.—Broom.—On a will bank in my garden I have several clumps of common Yellow Broom. Being desirous of increasing the size of the clumps, I transplanted several bushes last October, but I find that all beheaded. Can you inform me when Broom should be transplanted, and whether it can be taken up in the winter, and if so, at what season? My bushes are cut from cuttings, and I do not multiply. If I prune them or cut them down will they grow up afresh, or how can I improve them, and at what season?—S., *Renfrewshire*.

4096.—Roses not thriving.—Roses do not thrive in my garden; the neighbourhood is too bleak and dry. Gravelly subsoil, very elevated, dries out quickly. What are the best kinds to try? I should like to grow Roses of some kind, giving the preference to suitable kinds for button-holes work. Would not the hardy kinds of *Tea* Roses succeed? A few that I have planted alongside General Jacquemont have come through the winter better of the two kinds. Locality, Wolverhampton.—C. N. P.

4097.—Tropaeolum "Fireball."—Will anyone kindly inform me if *Tropaeolum "Fireball"* is the same as *Tropaeolum speciosum*? I obtained some strong tubers of the latter about two months ago from Mr. Henry South, Gardener, Yetholm, who advertised it in *GARDENING*. I planted the tubers 4 inches deep, as he advised, and put some in all the aspects—north, east, south, and west. It has grown beautifully, but I find as yet, I do your Jersey correspondent, that it is least in the south aspect, and that it is the county of Durham. I should be glad to know if it would succeed as a greenhouse climber.—J. H. G.

To the following queries brief & literal replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4038.—Ologium onrragata (B. M.).—You must not put this plant in strong heat. I do not say it will not grow, but I do make the assertion that you have very little flower from it. The plant grows naturally on the Madras Hills, and I am told always upon the north side of the hills. And I have always succeeded with this plant best when it is placed in the house amongst the *O. longosumma*.—M. B.

4890.—Onoidium hastatum (George Jenkins).—How you receive the name of your flower, and it is a very pretty species, for which we have to return thanks to the Messrs. Low, of Clepton. I have seen the plant in some of the Messrs. name *O. medium leucocolum*, but it is a very different plant to this, which was introduced by the Messrs. Lodges upwards of fifty years ago; but it was the Messrs. Low, of Clepton, that made the plant popular by introducing it in quantity about eighteen years ago. It has a wide distribution in Mexico.—M. B.

4900.—Stephanotis not opening (M. Banks).—You do not get the spire to open now. I cannot think why readers do not ask before the mischief is done. If you had asked before you removed this plant to an arid atmosphere you then might have had a word of advice given, but I am thankful that you now cannot blame old "M.B." for misleading you. And I do not know why you took the trouble to tell me how you had grown this plant in a nice warm stove, and that, not wanting it to flower before the middle of July, you had removed it to a greenhouse, which has been open day and night, at once, and you have reaped your reward, for the bulb which you suppose is as dead as a door-nail.—M. B.

4901.—Ants, &c. (H. H. L. G.).—Your first question is best answered by an indirect reply. There is no need to destroy the ants, as they are not doing any harm to your Beans, but only visit them to collect the sweet matter exuded by the "Insects," which are one of the aphides (*Aphis fabae*), commonly known as the Black Colpin, Black fly, or Collier. 2. The ants do not in any way create the insects. 3. The aphides may be killed by washing the plants with 4 lb. of soft soap, the extract from 4 lb. of Quassia-chips, and 100 gallons of water. Or the tops of the plants may be cut off, taking care that they are not left among the plants, but carried away in baskets and burnt. Remove all Docks and Thistles, on which this *Aphis* also feeds.—G. S. S.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to names should always accompany the parcel, which should be addressed to the Editor of *GARDENING*, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Clinton.—Probably *Lilium pardalinum*.—J. F.—We cannot undertake to name garden varieties of *Fuchsias*.—F. H.—Numbers all detached, so we cannot name.—M. S., *Redhill*.—*Justia carnea*.—Andrew Forth.—We do not name varieties of *Roses*.—A. F.—Both flowers are *Marguerites*.—K. G.—Dried up, and numbers all detached.

TO CORRESPONDENTS.

POULTRY & RABBITS.

4025.—An incubator.—Does not "Gardener's Wife" make a slight mistake in her first sentence? Chickens are hatched in incubators, but raised or reared in brooders or foster-mothers. I presume the querist is desirous of hatching some chickens, and asks for information on this point alone. She will understand that it is difficult to advise her fully without seeing the article which she wishes to employ. If the boiler cannot be made to stand higher than 8 inches or 9 inches from the ground some arrangement must be made for fixing the lamp below the surface, or there will not be room for the chimney. I should say a lamp ought to be specially made for the purpose; this might be made to stand on the oil-vessel in order to save space; there would thus be no stand needed as in the case of a table lamp. The chimney need not be more than 8 inches or so high, and of course it will conduct the heat from the flame to a spot where it will play upon the boiler itself. The greatest amount of heat will, of course, be forthcoming when the water can be made to surround a funnel or tube through which the hot air passes. "Gardener's Wife" must arrange for the water to maintain a temperature ranging from 103 degs. to 105 degs. Fahrenheit, and before she puts her eggs into the machine she must be satisfied that the heat is kept at a tolerably safe point. I presume she will use paraffin-oil for the lamp. This I have found safe, and when ordinary care has been bestowed in trimming and refilling the lamp, nothing has gone wrong.—DOULTING.

WHITE FLOWERS FOR CUTTING.

The demand for white flowers increases with each succeeding year, and no garden of any size is complete without a plentiful supply. Fortunately, all through the summer and early autumn months many plants with white flowers are very easily grown in herbaceous and mixed borders, and in their way quite equal to choice hot-house flowers. In the very front rank I should place White Stocks, and there are few to beat East Lothians sown in boxes in autumn. If pricked out into 3-inch pots, wintered in a cold frame and planted out in April, they will make grand plants in early summer, and last a long time. A *propus* of this Stock, it is rather strange that of the three colours—white, scarlet, and purple—there should be annually so much larger a percentage of single in the purple than in the other colours. White Sweet Peas are almost, if not quite, of equal value with Stocks. It is sometimes advised to sow Sweet Peas in autumn, but they want a lot of attention in the early season if birds and slugs are troublesome. I prefer to sow in February in 3-inch pots, hardening off and planting out early in deeply-dug ground. Of the several varieties of Spiraea valuable for cutting, preference must be given to palmata alba, a lovely variety whose feathery plumes are exceptionally light and graceful. A stock of forced *S. japonica*, planted out and allowed to remain in the ground over one season, will also furnish an abundance of flower. Small or Cactus-flowered White Dahlias are not common; indeed, among the new varieties of the last two seasons one hardly finds a white variety. The best for cutting are still Gilding Star, Lady Blanche, and Camelliflora in the pompona, and Constance and Mr. Tait in the Cactus sections. I should like whilst on the subject of Dahlias to sound a note of warning as to the depredations of earwigs. These insects are very numerous and troublesome this year, and in common with the foliage on Peach and Nectarines, I noticed quite early in the season that the leaves of the Dahlia were getting badly punctured. The use of the 2½-inch pot inverted on the top of the stake (with a little dry hay to tempt the insects to resort thither after their slightly depredations) has proved effectual. I have shaken as many as a score some mornings from each pot. There are few better white flowers for summer cutting than the white Antirrhinum. I have a goodly display of this on the herbaceous border, and a wonderful profusion of flower is produced from individual plants. Many varieties of the annual Chrysanthemum are nearly white. As this is of easy culture, quick to come into bloom, and very free, standing also a long time in water, it can safely be included in any list of flowers for summer cutting. In common with the majority of better class annuals, this should be sown in a little warmth about the end of March. Plants are thereby secured early, and if put out as soon as possible the flowering season is considerably lengthened. No mention of white flowers would be complete that did not include the

hloom perfect in form, substance, and colour as be secured. It is not so free with me as the old Crimson Glove, but still quite indispensable as a button-hole flower in its particular colour. Attention has been directed on more than one occasion to the value of Godetia for cutting. Duchess of Albany is a white variety of exceptional merit. I question if there is a more thoroughly useful plant from a cut-flower point of view than the Double White Yarrow (*Achillea ptarmica* fl. pl.). Although not altogether what one might term a high-class flower, lacking the sweetness and grace of Stocks, Spiraea, and other things previously mentioned, it is invaluable for filling up wreaths, crosses, flower-baskets, or to meet any large demands of a similar nature. As summer declines and the days shorten, the supply of white outdoor flowers in quantity seems to increase, and will last until the approach of frost—plenty of White Annual Aster, Summer Chrysanthemum, also *C. maximum* and *uliginosum*, to mention a few of the many good and useful flowers. There are some white flowers, which, although admirable in themselves, are yet from some cause or other not admissible in quantity on the herbar. Take, for instance, *Lilium candidum*. What a miserable appearance this has presented of late years in the majority of gardens! Foliage brown and bad, and flowers nothing like so good as they would be with clean, healthy foliage. Powders, in the shape of "anti-blight" and "mildew preventor," are only partially effectual. I was wondering the other day how two or three applications of Bouillie Bordeaux would answer. It might act as a preventive if the foliage was well damped with the same at intervals before the appearance of the disease. The White Herbaceous Phlox is handsome in appearance, but not of much use for cutting on account of the short time it lasts in water; still, we are glad to use it and renew frequently, for there are few white flowers that produce such splendid heads. Heliotrope White Lady would be a grand flower for cutting were it not that a failing similar to that of the Phlox has to be feared against it. I should like to say a good word for White Verbenas. Given a variety with fairly long flower-stalks, one is never at a loss for a supply of white blooms, and provided they are not kept too long before being placed in water, they will remain fresh for several days, and the delicate perfume is much appreciated. Very pretty nosegays can be made with a mixture of White Verbenas and Sweet Peas, a little *Thalictrum adiantifolium* foliage, and a fringe of Pheasant-foot *Polygonum*.

E. BURRELL, *Claremont.*

Sempervivum arachnoideum.—In or out of flower there is always something to interest one in the several kinds of wobbled Sempervivums. I think, however, that in this season in particular the non-flowering rosettes are more striking than usual, because of the snowy whiteness of their silken webs. A fresh crop is being sown, as it were, just about this time, and when the rosettes are well covered the plants are very attractive. In early spring the plants of the above variety have a reddish

purple hue. On the open rockery in a high and dry position, and surrounded by small stones to prevent the rains washing the soil into the web, it is very attractive. The position can hardly be too hot or too dry. To have it in its best form the rosettes should be pricked out singly on each apart, carefully avoiding planting in lines, and in this way covering a large, irregular space on the rockery in a sunny position. Make the ground firm before pricking out the plants, and when planting is completed sprinkle some clean fine gravel or similar suitable material among the rosettes. Given this treatment, the plants will flower more freely, it is true, and though some may object to this because of the obvious result of such flowering, it should be remembered that only a few of the largest would flower in the first year, and that the remainder would form a very pleasing feature for a long season, while those that bloom may easily be replaced when flowering is complete. Offsets are produced in plenty; consequently some large patches may readily be formed. *S. a. Lageri* and *S. a. Powellii* are two good kinds worthy of attention.—E.

RAISING SEEDLINGS.

I SHOULD like to draw the attention of amateurs and other readers of GARDENING to the interesting practice of raising Geraniums, Begonias, and many other plants from seed by just giving my experience on four seeds only. Last summer I picked four nice seeds off one of my Geraniums (*W. Beahly*). I put one seed in each of four small pots. These seeds soon came up, and, to my surprise, each one of them came quite different in foliage, so it struck me that there would be different coloured flowers. I took care of these through the winter, and the first one that flowered turned out to be a most beautiful salmon. I sent the first bloom to Mr. Jones, of Lewisham, and asked him for his opinion on it. He wrote to say it was the "most lovely colour he had ever seen" and offered at once to buy it if I would part with it. The next of these seedlings opened soon after, and is like the parent only much brighter in colour and the flower seemed to me to be smoother; this is evidently an improvement. The third seedling flowered and is a lovely salmon. If anything, I think, better than the first that I sent to Mr. Jones. This is in bloom now and can be seen by anyone who would like to satisfy their curiosity. The last seedling to open is a beautiful bright pink, a lovely colour and an enormous truss. I see the first pip is just opening this morning (July 5th), and looks as though it would be well worth anyone's while to grow. Now these four plants have been most interesting to me from the first, and I think amateurs could amuse themselves profitably by growing their own plants from seed.

W. COTTON.

4060. — Shading for a greenhouse. — A very cheap and good shade may be made by mixing flour and water with a little whitening; and you can also have lime or whitening made thin by mixing milk with it. A good shade is also made by dissolving Brunswick-green, so as to make it like this paint. These put on will provide a very good shade, very cheap, and easily removed. Such preparations as Summer Cloud, and others that are advertised in these columns, are efficacious.—C. T.

GARDEN WORK*

Conservatory.

Cottings of Hydrangea just getting a little firm will strike now in the propagating frame kept close and shaded. They do best in small pots singly. Myrtle, Oleanders, Spasmadina striosa (a useful winter-flowering plant) will strike freely now. All the winter-flowering Chrysanthemums are now in the flowering pots and are growing freely. If black-fly makes its appearance use the remedies which have been found most serviceable in the past. The other day I found a cultivator, who grows 10,000 plants, dipping them in a tub filled with Sunlight soap in solution. This may be used as a preventive. A pound of soap is enough for eight gallons of water, and this in a tub will dip a good many plants, so the remedy is cheap one, and may be useful for other plants attacked by insects. The soap is boiled in a smaller quantity of water till dissolved, then more soft water is added to make up the quantity. The Erythras are rather striking conservatory plants for summer droosals. Many years ago we used to grow E. Crataegifol. lately, groups being made of it on the lawn; but there are other forms of it, all of which are useful and interesting. When the frost comes the plants are cut down, the roots potted and kept through the winter in a dry cool house in a dry condition. Fuchsias will now be at their best, and must have plenty of nourishment. Plants with pots full of roots must have attention. There has been scarcely any improvement in the Fuchsias for the last twenty years, the reason being Fuchsias are not fashionable now, and sellers have left the beaten track and are searching after novelties. In a large conservatory the Fuchsias should be planted out where they can either form wood-shed bushes, or be trained up the rafters, and led up into the roof. Leobanulmia hiberna major is a good plant for the young ambitious plant-grower to try his hand upon. In the days when hard-wooded plants were more generally grown than they are now, a good specimen of this L. hibernica, well-bloomed, was taken as a sure sign of careful culture. Hoyas. Celsia is another old favourite sure to be admired when well done, requiring somewhat similar treatment. The chief point in the successful culture of old-fashioned hard-wooded plants are the potting and watering. The best peat, containing plenty of fibre, is required. The drainage must be perfect, and the soil remained in firmity around the plants. Careless watering is the bane of hard-wooded plants. Look over them twice a day, and water only those which require it. It will not do to anticipate nor yet fall into arrears. Peromoea elegant and Cantua dependens are not commonly met with, but careful plant-growers find no difficulty with them.

Stove.

Amaryllidaceae which have done flowering will require less water, but the work of their retarding to rest must be a gradual affair. Raising seedlings from good varieties is the best and cheapest way of getting up a stock. Buy a few good varieties to start with, hybridize, and save seeds. There is some merit in this before seedling flower, but the result will be interesting and profitable. Shift on Polkaetia, Euphorbia, Cranthemum, Gardenia, and other flowering stove plants. Young plants of nearly all the flowering stove plants can be easily rooted from cuttings. Gardenias are sometimes planted out in beds of rough peat, and when the flowers are required in a wholesale way, and a house can be given up to them, the planting out supply answers very well. One of the difficulties in the culture of these plants is the usual presence of mealy-bug. If it were possible to get hold of a perfectly clean stock their culture would be comparatively easy where heat was at command. What a pretty little specimen Hoyas bella makes in good hands! It must have good fibrous peat, with a little leaf-mould and plenty of sand, and charcoal, broken up fine, to keep the soil open. This plant grows well in a basket suspended from the roof. Shift on yucca, plant of the cactaceae, C. mamillaria, C. fragrans, C. gl., and Aphelandra surculosa, and others. These are old-fashioned plants, which used to be had in good condition when there was a bark-out in the stove. The bark-bed was a great help to the plant-grower, not only in furnishing a little root warmth for plants which required it, but it created a genial atmosphere to a more regular way than can be done by damping floors, &c. Use the hind as little as possible where foliage plants are grown, especially Cereus. Let nothing softer for want of water, nor yet air, in the opposite direction. The unheated greenhouse may be as charming as any other, or even more so now. If kept fairly close stove plants and tropical Ferns will do well in it, and all the usual kinds of greenhouse plants will be quite at home under glass now, with the lights open eight or nine days. But the winter must be thought of, and the Lilies, bulbs, and other things which can bear the rigour of winter with only the shelter of a glass-roof, must not be neglected. Laurestinus, Rhododendrons of the Indian type, Solomons's Star, and other smaller things which for the moment, perhaps, are standing outside will be better plunged in Cocoa-ash-fibre or a heap, to save watering and to keep the roots cool. Chrysanthemums must not be crowded on together, or the plants will grow up weakly.

Hardy Ferns

are very charming, and may be successfully grown in pots, but in a time like this they should be plunged out to a shady border, and be shaded with tiffany during the hottest part of the day. Spores should be gathered as they ripen, and be sown in pans of soil and placed in a cool frame. I always think of ferns to more do good to keep in stock than are the exsiccated species. It is true some species, such as Polypodium anglicum, proliferum, and its variety, produce young plants on the old fronds, which only require to be taken off and pricked out in boxes of soil. Scolopendrium ramosum can be propagated by pulling an old plant up into single fronds. There is a germ at the bottom of each frond, which in a comparatively short time will develop into a plant.

Cold Frames

are for the most part occupied to do Ciceraria, Cyclanthes, Calceolarias, and Primulas, single and double. If there is

a small frame at liberty it may be devoted to the propagation of the Carnation. Seeds of choice alpine may be sown in pans of peat, leaf-mould, and sand, and placed in a frame and kept close and shaded for a time. Set the pan in a cool, shady position.

Window Gardening.

Cactuses form very interesting window plants, and but few people realize what an immense variety there are to choose from suitable for the windows; being of small stature, and for a considerable part of the year requiring very little attention, they must be well supplied with water, and growth encouraged. Any plant requiring more pot room should have attention now. The soil should be composed of very turfy loam, old leaf-mould, pieces of brick broken up, fine crooked charcoal, and sand.

Outdoor Garden.

Among the hardy plants which are flowering well now in the dry, hard ground, and which may be recommended for cutting, are Campanula Hendersoni, dwarf, and very free, and more pleasing than the Bell-flowers usually are. C. carpatia is also very effective, both in the border and also on the rockery. (Kochera Youngi, yellow, and G. speciosa, white, are both good, and an old-fashioned plant, Linum catharticum, suitable either for rockery or warm border, is now a mass of charming yellow blossoms, as free from frocks and emburms as if there had been no heat or drought. For cutting out Coreopsis lanceolata and C. grandiflora, a dwarfier variety, are valuable. The Gaillardias, Irlieum patulum, and Stenactis speciosa are also good. All the above should certainly be in every garden, as being among the most useful hardy subjects. Get on with the propagation of Carexones and Finks as far as possible. One of the most successful propagators of the Carnation I know strikes his cuttings in 4-inch pots filled with ordinary red sand, such as is used by builders. Calling upon him the other day, I found him busy potting in Carnation cuttings by the thousand. The pots of cuttings are placed in a acid pit, with the lights whitewashed, and nearly every cutting strikes in the sharp red sand, when they are potted off immediately. But not people layer their Carnations, and layering make good plants, undoubtedly, but those who care a straw to lose the possibility to draw nutriment from the parents as long as possible. On the other hand, layering is tedious, back-aching work, and those who can make use work with cuttings have the best of it. Hollyhocks, except wern well cared for, are making a poor show of it this season. The side-shoots, when getting a bit firm, cut at single eyes, will strike and make good plants. I have struck many that way of the named varieties.

Fruit Garden.

The drought continues, and Firmes and Peaches are in a terrible plight with red-spider. It is, of course, quite impossible to either mulch or water all the fruit-trees in the country, but those who care a straw to lose the possibility to draw nutriment from the parents as long as possible. On the other hand, layering is tedious, back-aching work, and those who can make use work with cuttings have the best of it. Hollyhocks, except wern well cared for, are making a poor show of it this season. The side-shoots, when getting a bit firm, cut at single eyes, will strike and make good plants. I have struck many that way of the named varieties.

Vegetable Garden.

In many gardens Potatoes are small, and where the skins are set it will be better to lift them, as superabundance may set in. In rain comes in quantity, and then the quality will be injured. The best course will be to lift all Potatoes which are ready and have done growing, and sow Turnips, or plant Cauliflowers or Yelich's Autumn Bicolour, or sow Winter Spinach on the land. Of course, nothing will grow on newly-sirred lent or in bad air without water, and thus watering will have to be repeated when required till rain falls. In sowing seeds in smallish quantities, first soak the drills thoroughly, sow on the damp soil, and cover with the fine dry soil now. The dry soil will prevent the escape of the moisture from the land, and a shade can be supplied very little water will be required for some time. Only the very best culture will secure good Lettuce now, and one of the principal items of good culture in a dry time is mulch with short manure. Where Mushrooms are grown the old coes, when broken up, form fine mulching material, and may be placed between the plants 2 inches thick, covering the whole surface, but not piling it up to the depth of anything, as that will do harm. Sow Brown Cos Lettuce and Green Curled Endive in quantity now for autumn and early winter use. Another sowing should be made in about three weeks. Te up Early Celery, and wrap paper round the plants to start the blanching. Old newspapers will do very well. Several thicknesses should be used. Cootions to give plenty of water, with stimulants in moderation, the Cardoons, Olive Artichokes, Cauliflowers, and any other crop which has reached the extreme limit of its power of endurance. E. HOBBS.

Work in the Town Garden.

This has been a very trying time for things under glass. (For that matter, in the open air also, though in this case the occasional watering and a good deal of shade, but fibre or something of the kind goes a long way, in

doore the watering has been a terrible business, and there has been very little to show for it either, for the flowers are scarcely open before they either drop or fade. Shade has been an absolute necessity for almost everything, and even then, and with abundant ventilation, the atmosphere has been really stifling at times. I have been trying to get everything possible planted out-of-doors, and am still at it, for I find that under present circumstances they thrive far better in the open, and require very much less care and labour also. Tuberosa Begonia, in particular, does amazingly wonderfully sturdy habit and healthy appearance when planted in the open ground, and flower profusely, but an abundant supply of water is an absolute necessity, certainly until they become thoroughly established. It is as a bedding plant that the Begonia is destined to shine in the future, I feel sure. Of course, the plants must be thoroughly yet gradually inured to full exposure before being planted out. What charming and delightful things Streptocarpus are for conservatory decoration. I find them more easily grown than either Begonia or Gloxinia, requiring less heat than the latter, and being less liable to damping and decay than the former, while the growth is exceedingly dwarf, the flower-stems "wiry," and the blooms are produced continuously, and in the greatest abundance. The velvety foliage, too, is decidedly head-ome, but in order to keep this in good condition, the plants must be shaded from all strong sun. I hear numerous complaints of Tomatoes dropping their blossoms lately; in many cases this is due to want of moisture, either at the root or overhead, though the extreme heat and drought have also a good deal to do with it. There is as much danger of the plants suffering from want of water under present circumstances as there is of giving too much in the autumn, winter, and early spring. Where other plants are growing in the same house the glass must be studied in some way, and this greatly tends to weaken the growth and predispose to dropping of the blossom. Cyclanthes standing out-of-doors must now be watched, and directly they show signs of retarding growth, they should be repotted and be placed in a lightly-shaded frame until well at work again. Old Chinese Primulas, too, will soon need repotting, and should be similarly treated afterwards. Keep F. obscurata, &c., moist, and shaded. B. C. R.

THE COMING WINTER'S WORK.

Extracts from a garden diary from July 15th to July 22nd.

Sowed Cabbages for spring use. The kinds are Ellam's Early and Kidland Market. As we are much bothered with seed eating birds, the seeds were first dressed with red lead. The ground was thoroughly moistened in the evening, the surface raked smooth, and the seeds sown next morning, and covered with sand. Every good seed will grow. Sowed Pink Spinnock and Tropic in some way, and this greatly tends to weaken the growth and predispose to dropping of the blossom. Cyclanthes standing out-of-doors must now be watched, and directly they show signs of retarding growth, they should be repotted and be placed in a lightly-shaded frame until well at work again. Old Chinese Primulas, too, will soon need repotting, and should be similarly treated afterwards. Keep F. obscurata, &c., moist, and shaded. B. C. R.

4097. — Tropaeolum Fireball. — This is a very different thing from T. speciosum, being of larger and stouter growth, while it lacks the tuberos root, and is propagated by means of short cuttings. Here, in the south, T. speciosum does best on a north, east, or west aspect, but in the north it is different. T. Fireball makes a capital greenhouse climber, and to a moderate temperature flowers profusely all the winter. — B. C. R.

— This is very different to the kind T. speciosum, the former being scarlet in colour and one of the so-called "Nasturtiums." It is used for the greenhouse largely. T. speciosum is a quite hardy plant, and creeps about charmingly in a moist, cool spot, such as is given to shrubs; but you know all about it, apparently, only the two kinds are quite distinct. The garden is the proper place for T. speciosum, or Flame Nasturtium, as it is also called. — C. T.

* In cold or northern districts the operations referred to under "Garden Work" may be done from the first of a fortnight later than is here indicated, and in many good results.

FRUIT.

SOME GOOD EARLY PEARS.

For private use the very earliest Pears will never become much grown. Not only is there other good fruit in season, such as Peaches and Nectarines, but the quality is anything but satisfactory; and moreover, as soon as ripe, they are quickly over. Of course, there is one notable exception, this being the well known Jargonelle, which has always been a favourite and will always remain so. By early Pears it must be understood that I am referring to those which ripen up during September and October. Such Pears as these ripen so as to be of good quality when grown in the open; at any rate, they may be so grown in the southern or midland districts, where they invariably come of very high quality, being much more juicy, and, moreover, they keep better. Certainly they may be grown against walls either with an eastern or western aspect, but as a rule this latter aspect is generally retained for the later ripening varieties. For a high-class dessert, Jargonelle heads the list but, as a rule, this is an August Pear, and although so early, it invariably comes very good from an east or west wall, although, as is well known, many a garden can boast of some fine old standards, and as such it will succeed throughout the length and breadth of Britain. As a September Pear, Williams' Bon Chrétien is a favourite with many people, although by some it is

succeeds this kind. I now come to that best flavoured of all October Pears—Beurré Superfin. This is a grand Pear, with a vinnus flavour, and although it comes larger when grown against a wall, I think the flavour is improved when grown in the open; here it takes on that russet appearance, and although to outward look it does not appear ripe, yet it is, and anyone might be deceived. The late Mr. Haycock, who grew and knew Pears so well, told me that he always found it better in flavour when grown in the open, although at that time he hailed from Kent, and which, it must be remembered, is a highly favourable county. Whether grown against a wall or in the open, Fondante d'Automne will always be found of the highest quality. This Pear also has the advantage of keeping longer after being ripe than the majority of October Pears. Beurré Hardy will close my list of good quality early or October Pears. This, again, is a good Pear, coming much larger than the preceding, and from an east wall I have had the fruits very large. On cold soils I should be inclined to grow both of these latter named Pears on an east or west wall, the latter for preference. For extra quality in flavour out of the above-named varieties, and omitting Jargonelle, which should be in every garden, I should select Beurré d'Amanlis, Fondante d'Automne, Beurré Superfin, and Beurré Hardy, taking them in the order of ripening, although the season of each may be prolonged by either growing on different aspects or gathering at intervals of twice, and Fondante d'Automne at three or four times—If.

some experiments undertaken by Dr. Riley, Entomologist to the United States Department of Agriculture. Much interesting information is given. He says that recent experiments made have thrown much light on the comparative value of different arsenical mixtures as insecticides, and as to the relative harm they do to foliage. It was found that heavy spraying with one pound of Paris green to three hundred gallons of water did not injure the foliage. London purple used with the Bordeaux mixture to the proportion of one pound to fifty gallons was entirely harmless to the Peach and Plum. It was found that the eldest leaves were most liable to injury, and that dews, and probably direct sunshine, increase injuries done by arsenites to foliage. Leaves kept perfectly dry can hardly be injured by them, and those suffering from fungous disease are more susceptible than healthy ones. Freshly mixed and applied, London purple is most injurious, while freshly mixed and applied white arsenic is less injurious to foliage. The longer the mixed white arsenic stands the greater danger of injury. A great many experiments were conducted with a view to combine substances which are known to have both insecticide and fungicide qualities. While the results have been variable, it would appear, on the whole, that the combination of an insecticide does not add to the efficiency of a fungicide, but often detracts from it. The reverse of this does not hold true, as experiments have proved that while the Bordeaux mixture, combined with arsenite, does not act well as a fungicide, it is decidedly beneficial as an insecticide, as the arsenite can be used so much stronger. It was found that one pound of Paris green to five hundred gallons of sulphate of copper solution proved very injurious to trees, but that one pound of Paris green in two hundred gallons of Bordeaux mixture reared a large crop of Plums, while other trees not treated lost their fruit from the Cureuligo. These few particulars may be of use to you, as the Paris green and Bordeaux mixture preparation are most efficacious, as far as I have seen.—C. T.

Pear "Beurré d'Amanlis."

disliked on account of its highly perfumed flavour. As a market Pear, it will always be grown, and in America it is very highly esteemed, and is known there as the Bartlett. Like the majority of early Pears, it keeps but a very short time, and unless it is gathered before it parts freely from the tree it becomes mealy instead of juicy. This is where some people make a mistake with the Jargonelle by allowing it to hang until it parts easily from the tree, under the impression that this variety must be gathered and eaten from the tree, as sometimes described.

BEURRE D'AMANLIS (here figured) is a first-rate Pear, and with many it commences the Pear season. This is a very strong grower, and also a free bearer. Triomphe de Vienne I should have mentioned after Williams' Bon Chrétien, which it somewhat resembles, but of better flavour. This variety is not very well known, but its merits fully entitle it to be. Mme. Treve is a very prolific Pear; it also grows to a large size when freely thinned, and does capitally in the open. Fondante d'Automne is a very richly flavoured Pear, and succeeds admirably in the open, even on a cold clay soil. Birds have a particular liking for it, for I think they will find out this and attack it before any other. It has, however, one great fault—viz., that of quickly decaying in the centre, as soon as ripe. Being of such a nice flavour for an early or rather an October Pear, it is well worth planting. Souvenir du Congrès is a very large Pear, somewhat resembling Williams' Bon Chrétien in appearance, but much larger, and

4091.—Orchard (14 acres) destroyed by insects, caterpillars, &c.—This is a big undertaking, and in the case of trees planted 40 years the cleansing is not likely to be remunerative. Better arrange with the landlord to have all the worst trees grubbed up, at any rate, and young trees planted, after the thorough preparation of the site. If he understands his own interest he will hardly object to this; then as soon as the leaves are down give the trees a thorough dressing with newly-slacked lime, and place green bands round the stems. In the spring spray with Paris blue or London purple two or three times at intervals of three weeks, and wash the Plums with a strong solution of sunlight soap, boiled, 3 oz. to the gallon.—E. H.

As regards American Blight, you will find full information respecting its treatment in GARDENING, June 24, p. 239. You do not say what the trees are, and I should advise you to try a preparation of Paris green, a substance that is very much used in this country and abroad, France in particular, for dressing trees. It is used for spraying Potatoes as a remedy against the disease to great advantage, but I do not think has been much used yet in this country, although it will be doubtless in the future. There are two substances used, the other London purple, and I should advise you to try this new treatment in dealing with such a large area. I have had no experience actually of the preparations myself, but have seen the good effects of their proper application. So much destruction is wrought to fruit-trees through pests that one is always willing to give any information at command. I will give you a few particulars of

Periploca gracca.—On no account can this Periploca be called showy, yet when profusely laden with bloom it is very pretty, while close inspection will reveal the fact that the individual flowers are most interesting. It is a free-growing climber of a deciduous character, whose leaves are deep-green, from 3 inches to 4 inches in length, and firm in texture, while the flowers are each about 1 inch in diameter, five-rayed, and of a purplish-crimson colour inside, the reverse of the petals greenish-yellow. These blooms are borne in clusters of about a dozen together, and in the case of a thriving specimen where fully exposed to the sun they are often so numerous that the entire upper part of the plant is quite a mass of blossoms. The scent of the flowers is by no means pleasant. The plant itself is perfectly hardy.—T.

Primula scotica.—How lovely is this gem at the present, blooming for the second time after the recent rainy weather, and how superior in size are the summer-borne flowers to those of spring. It is so refreshing, too, to see this little beauty keeping company with late-flowering *P. sikkimensis*, *P. reticulata*, and *P. japonica*. Its violet-purple colour is of the intensest hue, and the stout little scapes of 3 inches high bravely sustain the flowers through the most windy weather. I wonder this plant is not better looked after, because you have only got to pick off the seed of the spring-borne flowers, rub it out into a little peaty damp soil, and it comes up thickly during late summer, and you have a group of blooming plants for the following spring. Treated this way, as an annual or biennial, it well rewards the little care needed, though I possess plants at least three or four years old. May I suggest a cross between this small species and the larger *sikkimensis*? One can imagine not only curious results from such a cross of the pigmy and the giant, but progeny of considerable merit from the florist's point of view.—B.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

OUTDOOR PLANTS.

NOTES ON CARNATIONS AND PICOTEES.

The parent of the garden Carnation is *Dianthus caryophyllus*, the wild Carnation or Clove Pink, which loves to scramble about on old castle walls and send its roots into the mossy chinks. It must be a poor garden in which some of the varieties—originated from the wilding form—are not present. The most peculiar Carnation is the Old Clove, a crimson, fragrant flower, spreading out into broad clumps; but often sadly afflicted with a disease called "gout," a peculiar swelling of the stem. In many places it refuses to grow, even with the most kindly treatment. The florist has divided the Carnation into several sections, according to the disposition of colour on the petals. Thus we have scarlet hizarre, pink and purple hizarre, purple flake, scarlet flake, and rose flake, besides yellow ground, faucy, and horder varieties. I propose at first to deal with the border kind, which those who merely wish to have a pretty garden, and not undertake the culture of the Carnation for exhibition, should commence with. The plants for the horder or bed should not be grown at any period in pots, as customers with those for exhibition, and the culture that applies to the Carnation is also suitable for the Picotee. During the past few years raisers of new Carnations have been busily at work, with the result that a fine selection of good hardy border varieties is at command. A typical garden Carnation should be of strong growth, producing plenty of "grass," and here I may mention that "grass" is the florist's term for the leafage, and throwing up on strong, sturdy stems an abundance of flowers, which do not split the calyx. Many of the older forms, and the Clove Carnation is not free from this glaring fault, produce blooms that burst the calyx, the mass of petals proving too powerful for the shell, so to speak, in which they are confined. This is a very important point, as bedraggled petals, tumbling out of their calyces, have an unightly aspect. The finest varieties have been pointed out in GARDENING, all having flowers that do not split. I saw last year a very charming picture of Carnations, the variety used being Baby Castle, which has blooms of a lovely salmon-pink colour, and produced in profusion. Edgings were found of it in the kitchen garden, and these supplied not only a large quantity of bloom for the house, but were pleasing to look at. Scarcely a split calyx occurred in hundreds of flowers. A moderately light friable loam is the soil that Carnations most enjoy, and if it inclines to be heavy a dressing of well-decayed manure or wood-ashes will effect the needful alteration. One of the chief enemies of the Carnation is wireworm, which effects in particular newly broken-up pasture land, and in such material Carnations should never be planted, else wireworm will prove mischievous. I have seen choice collections in the open ground entirely destroyed through planting a newly turned up ground. Strong stable-manure is not required, and, although we see it sometimes applied, is positively hurtful. Many amateur gardeners are filled with the idea that to make plants grow it is essential to give them rank manure to feed them, promoting strength and a superb display of the finest flowers. Such treatment is the reverse of suitable, and plants so treated show their dislike by promptly dying away. Loam should be the staple diet for Carnations, and in spring, after frosts are over, much good results from a top-dressing of loam, manure well decayed, wood-ashes, and, not least important, soil, a splendid fertiliser, giving rich-green colour to the leafage, and assisting to stop the depredations of wireworm. Always, as far as possible, plant Carnations early—that is, if from layers, in late August or September, so as to become thoroughly well established before frosts occur. When this is done, they will go well through the winter, and if planted in spring there is not a very long season for them to become well established before the display of flowers occurs. It is better, however, if the autumn planting is much delayed, to put them in pots, and keep them in a cold frame during the winter, planting them outside in the month of March or early April. As the flower spikes rise such must have a stake, or some form of support.

There are several advertised contrivances, but nothing is better than a deal or Hazel stick, which in country places may be procured very cheaply. Keep the stick as much as possible out of view, remembering that one wants to see the flowers, a point which amateur gardeners do not always seem to consider. The

PROPAGATION of the Carnation is not a troublesome undertaking. Layering of the shoots is the chief method, and about the middle of July, not later, is the time to proceed with the work, finishing it by early August. The first thing to do is to remove carefully the soil from about the plant, so as to form a very shallow basin, not more than 2 inches in depth. If the soil is not considered of sufficiently good quality for rooting the layers it may be replaced by a little light compost, friable loam, leaf-mould, and sand, into which the shoots can be pegged down; but in many soils the extra compost is not necessary, watering and loosening the surface with a hand-fork being all that is required. Remove the leaves from the shoots to within about the three top joints. Weakly shoots should not be layered. All will now be ready for layering, and with a very sharp knife make a slanting cut a little above a joint, so as to form a tongue. Unless care is taken the shoot will be cut right through and rendered useless, except as a cutting. Have in readiness plenty of short, hooped pegs, made from the spray of Pea-sticks, and peg the shoot down into the soil just above the tongue, which, in the course of about three weeks, will send out roots. Over the surface place a little of the prepared compost, and water them carefully through a fine roset-watering-pot. This will settle the soil, and they may be left pretty much to themselves, except for an occasional watering in very dry weather, until it is time to lift them for transferring to their winter quarters. The end of September is the time for this work, and try to get them all planted before frosts occur, as upon that depends in a measure their future success. It may be advisable here to make reference to the Carnation as a garden flower. Flower gardeners seem only now to begin to realize that the Carnation may be made to produce beautiful pictures of colour in bed and border. The old Clove has always held an honoured place, but there is now a long list of lovely kinds, strong in colour, effective, and pleasing in groups, clumps, or masses. In several of the finest English gardens the self-coloured Carnation—that is, those of one decided colour, or shades of one colour, hold a high place, dethroning the rigid hedges which held court through many years. Bold groups of Carnations, associated with Tea-Roses, form a charming picture, and the soil that agrees with one is also agreeable to the other. Even in the smallest garden much space may be advantageously given to this border flower, unique for colour, fragrance, and distinct beauty.

CARNATIONS may be propagated by cuttings, but it is not a favourite plan, as plants from cuttings never succeed so well as those from layers. There is much trouble, too, occasioned by attending to them. They may be struck in pots filled with light soil and thoroughly well drained. Artificial heat should be given to promote, in the case of winter-flowering varieties, quick rooting. It is most necessary not to give too much water, otherwise they will damp off wholesale. The utmost care is essential in this respect. When the cuttings are taken off in the summer, and it is often usual to select shoots which cannot be layered for the purpose, they may be drilled in light, well prepared soil at the base of a shady wall. Cover them with hand-lights, removing each day the glasses to wipe off damp, otherwise the cuttings will rot. When rooted they may be planted out or potted on, at the wish of the grower. The

PICOTEE is a charming flower, telling in colour, and, like the Carnation, divided into various sections according to the colouring. I have many and light rose-edged varieties, and the same distinctions in purple, the ground white—delicate associations of colour, but not effective in the open to the same degree as the more brilliant tones of the Carnation. The yellow ground Picotees and Carnations are not so satisfactory to grow as other types, and I should not advise the beginner to have much to do with them, except Germanie, a very good yellow ground variety.

4089.—Sweet Williams, &c.—The side-shoots of the Sweet Williams may be layered in the same way as its relation the Carnation is done. The Canterbury Bell is a more difficult subject for propagation in any other way than by seeds, and if the plant or plants of which increase is required are isolated these come pretty true from seed. They cannot, of course, be relied upon to do this absolutely; but if seeds are sown exclusively from one colour and no other grown near, the greater part of the seedlings will be of that colour. If Canterbury Bells, or a certain portion of them, have all the flower-spikes removed as they appear, some increase may be had by division of the root-crowns. This is a slow process, but it is a sure one of keeping plants true to colour.—E. H.

— If you only have one plant of each kind there will be no difficulty. All you need do is to sow the seed as soon as ripe, and it will produce plants true to the parent stock, unless your neighbour chances to have something different in his garden. In any case many of the plants will be true. You could divide the roots of the Sweet William in the autumn, but in the case of the Canterbury Bell you must take your chance with the seed. Sow as soon as the latter is ripe, and your plants will then bloom next year.—A. G. BUTLER.

— You will have no difficulty in propagating these. The Sweet Williams may be readily raised from seed, which should be sown in a well-prepared piece of ground in a rather sheltered position, and the surface made firm. When the seedlings are of sufficient size to handle pick them out about half a foot apart, and from thence they may be transplanted to the positions they are to adorn. The best time to sow seed is April or May, and there is a wide selection of varieties, varying greatly in colour. Another way to strike them is by cuttings in the month of June, which may be dibbled in prepared soil, over which place a hand-light; a position on a shady border will suffice. Take care not to give water too freely. They will strike well under these conditions. You can now get quite a selection of colours, and the double crimson is a splendid flower, each bloom like a little rosetta. A mass of this is very handsome. There is much beauty in the Sweet William, the handsome trusses and refined flowers being of great effect in the garden. The most effective are the selfs, or those of one decided shade, set off with a white margin. The Canterbury Bell may be also very readily raised from seed, and it is a charming flower; the colours vary, from pure white to deepest purple, through shades of rose and allied tones. The usual time to sow them is April and May, but it may be sown now, and sown in a warm corner in the open, where the surface of the soil is fine. Sow thinly, and when of sufficient size transplant. It may be also easily grown in pots for the summer decoration of the greenhouse, the seed being sown in spring. The plants when in pots and in full bloom are charming, if you get a good range of colours, especially rose, which I think the more beautiful of the series. Guard against getting them of too large size, as then they are coarse, the big Cup and Saucer type having little beauty compared with those of more normal proportions.—C. T.

— You may take cuttings of the Sweet William in the ordinary way, choosing stubby side-shoots, and if inserted firmly in sandy soil towards the autumn they will root and make good plants. I have never rooted Canterbury Bells from cuttings, and should say that you cannot do better than save all the seed possible, and sow it next April or May. If the seed is ripe now, gather and sow it at once.—B. C. R.

4095.—Broom.—Healthy young plants removed in October ought to grow readily enough. I expect they have suffered from want of water. The best plants are obtained from seeds, but they take some years to attain a useful size. On the whole, it would be better to procure plants from a nursery, which would be more likely to thrive than wild ones; they may be removed either in the autumn or in the early spring.—B. C. R.

— This plant transplants very well in a small state, but I should expect large plants to die, especially in a season like the present. Cuttings will strike in a shady place early in autumn, but the best way to get up a stock is to sow seeds. You might clear a piece of the wild ground during the winter. Stir it up again, and sow the seeds in spring.—E. H.

4095.—Box edging.—Cuttings from a bush of Box will not make a Box edging. The dwarf Box used for edgings is not the same kind. If you have no Box you will,

doubtless, be able to obtain it from a local nurseryman, the cost being generally 6d. per yard; 1 yard when pulled to pieces to furnish enough to plant three. In preparing the site for the edging dig it over and tread it down firmly, then add sufficient soil from edges of border near to make the ground the right height. Make it smooth, and heat it down firm with the back of the spade. Put down the line, and cut out the trench deep enough to receive the Box, leaving about an inch above the ground when all is filled up and made firm. If planted in dry weather the Box must be watered thoroughly till the weather changes. Better wait till autumn before planting Box-edgings.—E. H.

PERENNIAL CANDYTUFTS.

This is a beautiful and useful group of hardy plants, both annual and perennial, and it is with the latter as rock and spring border plants that I am now dealing. Evergreen plants, such as the Iberises, dwarf Vacciniums, and the like are indispensable to a rockery; they should be planted as much with an eye to effect in the dead of winter as when they are in full flower in spring. The hardy species are all evergreen, and as they mostly form dense, healthy green cushions, these take the bareness off the rockery in the dull months, as well as contribute to its beauty in spring and early summer. They are, however, most effective where they can hang over ledges, such as down the face of old walls, rocky banks, &c., and here, too, the more tender sorts would be much safer than if planted in the ordinary way or on the border. As spring bedding plants they are extremely useful, and they may be increased from cuttings in any quantity.

IBERIS GIBRALTARICA.—This, here figured, is a native of Gibraltar, and was introduced to this country about 1732. It is one of the most popular of the genus, and with its variety *hybrida* is in great demand for winter flowering. It grows about a foot or so high, closely branched and tufted, with leaves and flowers much larger and more ornamental than those of any other species. It is, unfortunately, not perfectly hardy, unless the plants when young are established in an old brick or stone wall, and even here they are apt to suffer, especially in wet seasons. It may, however, be easily kept in a cold frame or greenhouse, where it will continue in flower throughout the winter. As greenhouse subjects both the species and variety are invaluable, their compact habit, fresh green leaves, and abundance of lilac and creamy-white flower-heads come at a time when most required; indeed, they may be utilised at almost any time, as they are rarely out of bloom. Plants well hardened might be tried in warm nooks of the rockery, and with a small piece of glass to ward off excessive moisture they might do well. It is as a cool greenhouse or summer plant, however, that this species proves most useful, and as it is increased from cuttings or layers with the greatest facility, no fear of losing it need arise. The variety is more compact in habit than the type, with larger bunches of creamy-white or rosy-purple flowers. *I. Pruiti* is a native of Sicily, and one of the most beautiful and useful of the hardy kinds for the rockery or border. It is little inferior, indeed, to *I. gibraltaria*, with the advantage of standing our severest winter. The flowers, of a pure ivory-white, are produced in abundance in compact corymbs, and continue from early May until July. The stems are shrubby at the base, much branched, and rarely exceeding 9 inches in height. It is nearest to *I. Tenoreana*, but the leaves are smooth, not ciliated, and the flowers pure-white, not purplish, as in that species. It is a really useful species for the rockery, where it should be planted in gritty soil and facing east. *I. exaltata*, widely distributed in Southern Europe, is the dwarfest of all the species in cultivation. The stems are procumbent or trailing, not ascending, as stated in many books. It forms dense tufts of very dark-green, narrow leaves, quite entire, with somewhat ciliated margins. It is very free blooming, producing small bunches of pure white flowers from early April until June. It was introduced about 1740. *I. s. var. correnzifolia* is supposed to be a hybrid between *I. saxatilis* and *sempervirens* or *Garrexiana*. It is a very neat, shrubby plant, taller and not so densely matted as the above, and producing

its flat heads of white flowers from May to June. It is

VERY EASILY PROPAGATED from cuttings or layers, and is often used as an edging for walks, &c. It is very neat and effective when in flower. *I. sempervirens* is an autumn and winter flowering species, and unless in southern counties is not of much use as a hardy plant. The flower-heads are large, the flowers pure white and sweetly-scented; the leaves quite entire, smooth, and dark-green. It is a native of Sicily and Italy. *I. humilis* is a synonym. *I. sempervirens*: This fine species is the common perennial Candytuft of our gardens, and with its variety *Garrexiana* is the species commonly met with in small places. It is quite as popular as the yellow *Alyssum*, and deservedly so, as it requires little attention and is attractive in winter as well as summer. It is evergreen, half shrubby, spreading, and will be found useful for old walls and such-like places where plants can get a foothold. It grows about 1 foot high, and seems to flower more freely in a gritty soil than in any other. There are several garden forms, the best of which is *superba*, a really charming variety, free and effective. *Groeco*, &c. *I. s. Garrexiana* is a much dwarfier plant than the above, with smaller heads of white flowers, and a very useful rock plant. It flowers from April to June, and is a native of the Pyrenees, &c. *I. Tenoreana*: A common species in Italy, Spain, and Portugal, and known in some gardens under the name of *I. petraea*. It differs from all the other species excepting *gibraltaria* in the colour of its flowers, which it produces in profusion throughout the summer months. Like *I. gibraltaria*, it is not to be depended upon as a perfectly hardy plant, and when left out some little protection should be given to it. In a well-sheltered nook and in free well-drained soil it does well in the south, where its mass of purple flowers is always welcome, but in any case it can be easily treated as a biennial or even as an annual by striking cuttings in late summer and planting out in spring. It is well worth the trouble and is really effective when grown well.

K.

4059.—**Lilies and Irises.**—I regret that I misunderstood "Australasian's" first query on this subject, and I am equally sorry that I cannot give him much encouragement to embark in the culture of Lily bulbs for profit. Such Lilies

very low rates. It would never pay to grow them in this country. The common White Lily, the Tiger varieties (*umbellatus* and *croceum*) may be grown very well in good well-drained ground; but the Dutch offer them very cheap indeed. For instance, I can buy *croceum* at 12s. per 100, *tigrinum splendens* and *flora-pleno* at about 10s. per 100, all good blooming bulbs, these being trade prices. Really good bulbs of *candidum* now so much in request I can get for 15s. per 100. Auction room prices will frequently run 30 per cent. lower than those above quoted. As regards Irises the case is rather different, as many of the finest of them can be grown and increased in this country. I should, however, be sorry to rely entirely on auction room returns. Growers only send those what they cannot dispose of in any other way. Things very good or rare will make good prices, but I have seen plants and bulbs sold there for a mere nothing.—J. C. B.

4058.—**Creoper for a cemented wall.**—There is no other creoper but the *Ampelopsis Veitchii* that will cling to your wall. The seed of the variegated Hop and Canary Creoper should not be sown until the spring. The beginning of April is soon enough, and an ordinary greenhouse will furnish all the warmth they want. I find the Variegated Hop does very well in a sheltered position in the open; indeed, the foliage is then very handsome, but much wind disfigures its leaves and checks its growth.—J. C. C.

—Various kinds of Ivy, including the small-leaved variegated varieties, will cling to the cemented wall if fairly started. *Euonymus radicans variegata* may be tried, but there are no plants beyond the Irish and Virginian Creepers that will hold on firmly to a cemented wall.—E. H.

—The best thing for such a wall is the Virginian Creoper (Veitch's), clinging well even to such a surface as this; but you might with the aid of wire grow other things of greater interest than this, entailing, of course, the "wiring" of the wall. If you do not wish to go to this expense, rely upon the creoper named, as even the Ivy requires support of some kind to start with. But you will get much pleasure from the wall if a wire is run across, to which the climbers could be fastened or trained. Then you could go in for many beautiful things, as the *Pyraeantha*, *Clematites* of various kinds, *Jasmines*, *Honeysuckles*, *Roses*, particularly the beautiful *Gloire de Dijon*, *Tropaeolum canariensis*, and other interesting things; but this

A perennial Candytuft: *Iberis gibraltaria*.

as *anatum*, *speciosum longiflorum*, *Harrisii*, *Browni*, *Krameri*, &c., are grown in a climate that perfectly suits them, and are consequently imported into this country in large quantities. They are disposed of in the London auction rooms at prices that I do not think could pay English growers, even if they could command the same climatic advantages that the Japan and Dutch growers enjoy. As regards the North American Lilies, they are to be had in quantity from their native habitats, and some of the American trade growers offer them a

small selection will provide much beauty. The seed of the Canary Creoper may be sown in the spring, and the plants will make quick growth. It is a very pleasing feature, the leaves even attractive with their glaucous shade.—C. T.

Registering thermometers.—A spirit thermometer should never be exposed to the sun, as the heat is sure to cause the spirit to evaporate from the top of the column, and to condense at the end of the tube, which, of course, prevents the readings from being correct, unless the amount which collects is made to rejoin the column.

ORCHIDS.

ARUNDINA.

This is a very beautiful plant, and it takes the place of the *Sobralia* in the Western Hemisphere. I am asked to say a few words about this plant by "Mr. Todd," for the benefit of himself and friends, with whom he has shared a boxful of these plants from Sylhet. Well, this plant was introduced in the early days of the present century, and it flowered first in this country upwards of fifty years ago, but it remained a rare plant for many years—indeed, until Mr. Sander introduced this plant in quantity a few years ago. Orchid growers did not know much of the species. Some few other kinds have been introduced from time to time, but they have not long remained in cultivation. I am very glad you have got some living plants home, and I am also pleased to hear of your distributing them amongst your friends, because in this way you are safeguarding the life of the species, for if one fails in keeping the plant or plants alive another may keep them, and thus it will become the source from which you can get a fresh supply. To secure a fair chance of success with this plant, it should be provided with a somewhat light place in the stove or Orchid-house, which should have a nice moist atmosphere, and the temperature should never fall below 65 degs. during the growing season, and water should be freely given to the roots. The pots must be large, as they are coarse rooters, and they take up a deal of room, and as they require quantity of water to their roots they must be well drained, so that it may percolate away quickly, for this is a plant that cannot abide any sourness about its roots, and for soil use fairly fibrous peat, chopped up coarsely with the spade, and good fibrous turf loam, in about equal proportions, made sandy. In potting they should be kept below the rim of the pot in order to allow the plant to get a good supply of water during the winter season. These plants are best kept somewhat cool and drier, but not dry, and the temperature may fall as low as 55 degs. or 60 degs. without the plant suffering in the least.

A. BAMBUSIFOLIA: This plant has been a rare one in collections, and not known by many orchidists. In growth it very much resembles a *Sobralia*; it has slender erect stems from 1 foot to 4 feet high, with long, narrow distichous leaves, which become smaller upwards, and light-green. It bears on the end of its stem a fine spike of flower. This varies considerably in colour, but the leading charms of a good variety, sepals and petals spreading, of a charming rosy-pink, the petals with a broad streak of rosy-purple down the centre of each petal, lip rolled over the column, these side lobes about the same colour as the petals, the front lobe, undulated at the edges, and of a rich rosy-magenta, which colour is carried up round the recurved edges of the side lobes, throat white, bearing a flashy crest.

MATT BRAMBLE.

CYPRIPEDIUM CURTISII.

In answer to the enquiries of several readers, I will now say a few words about this plant, for which we were indebted in the first place to the energies of the Messrs. Veitch and Son, who introduced it from the Island of Sumatra some eleven years ago; but to the Messrs. Sander and Co., of St. Albans, we owe its great popularity, they having introduced it in quantity only a few years since, and I have seen many good forms which have sprung from these plants. It is one of those kinds which have marbled leaves, the upper side having a dull-green ground, which is tessellated with blotches of a darker green, the underside being of plain dull-green; the scape is single flowered, but the bloom is very large, the dorsal sepal being ovate, bright-green, with a white border, and deeper green longitudinal stripes, and the lower one smaller but similarly marked. The petals are slightly deflexed, having a white ground copiously spotted with small purple dots and heavily fringed with blackish-purple hairs, pouch large, dull-coloured, with a few purple veins. It is a very beautiful plant, and it is conspicuous from being quite devoid of the blackish wort-like spots which are such a distinguishing feature in nearly all the species which belong to the *barbatum* section of the

Lady's Slipper family. Many plant growers and plant lovers I know do not like *Cypripediums*, but I myself have a weakness for them, and I have frequently expressed my own conviction from the time when the members of the coriaceous-leaved section could be counted upon the fingers of one hand, that I am heartily in love with them, and I still retain that love, in spite of the great number of seedlings that have cropped up, and all of which I welcome, so long as they reveal distinctness and beauty, and one of the points particularly to be frightened and made gay is the pouch or lip. Well, then, this *Cypripedium* requires exactly the same treatment and warmth that suit *C. barbatum*—that is to say, it likes good strong heat and moisture, and it also likes a certain amount of shade during the hottest and brightest part of the day, using for soil a mixture of good peat-fibre and Sphagnum Moss, and a small portion of good, light fibrous loam, from which all the fine soil has been shaken. This loam is something fresh to recommend, but I have been taking a great interest lately in a collection to which this element has been administered, and with good effect too, so that my readers may take what I say in good faith without hesitation; but you must be sure that the drainage is kept in good open order. Water freely during the summer months, and during the winter keep the plants fairly moist, but never let them get quite dry, and all will be well.

MATT BRAMBLE.

PLEIONES.

CONCERNING his plants of this genus, "Duncan" appears to be in a sad way. He says: "What shall I do? My employer is so passionately fond of them, and I fear that I shall fail with them this season, for the leaves are turning quite brown already, although the bulbs are not more than half the size of the last year's ones." Well, now I fear you have been too fast with these plants, my friend. You have from time to time got the plants on, and from year to year they have been flowered earlier and earlier, so that they have naturally got to grow so early that they have got altogether wrong. Now, I do not like to see those plants flower too early. For instance, last season I saw in a garden belonging to a reader of this paper some flowering in the month of October. This is brought about through the potting of the plants too early, and, like friend "Duncan's," so it goes on until the plants get smaller and smaller, and they eventually die out. In the present instance, however, it may arise from too free an exposure to the sun, and from the atmosphere being kept too dry, and, therefore, I should advise "Duncan" to shade his plants during the hottest part of the day, and to keep the atmosphere moist. This will induce them, perhaps, to finish up their bulbs before losing their leaves, and if this occurs flowers will follow in due course, I should think; but in the event of their not flowering take the plants into the cool-house, and there let them rest in quietness, and allow them to rest as long as possible. These plants are all alpine, and from their habit of flowering during the winter months without their leaves, have retained the name of Indian Crocuses, and nothing can make the Orchid-houses more cheerful than these beautifully coloured flowers. *P. maculata* is the earliest, blooming in about the beginning of November, and the others following on through December and January; but as they are grown now I have observed that even the latest kind, *P. lagenaria*, is all over and done before December sets in, but this I look upon as wrong treatment. The plants should not be subject to too great a heat; it causes them to grow at a great pace, and they grow weak, and do not develop such fat bulbs as when grown, say, near to the glass in the *Cattleya*-house, kept nicely moist, and with a good amount of ventilation, and this too may be given principally at night. In this respect I am quite at home with some of my friends, for I do not agree with my earlier teachers, who taught me to shut the houses up close at night. In potting these plants the drainage should be of the first importance, using for soil a mixture of peat, leaf-mould, loam, and Sphagnum. Water freely when growing, and when the growths are finished, and the leaves fall, they may be kept fairly dry and cool; but I do not like the temperature to fall much below 50 degs.

I hope what I have written will be of some service to my friend "Duncan," and he may depend upon it, in this and every other trouble, he has an anxious and sympathising friend in
MATT BRAMBLE.

HOUSE & WINDOW GARDENING.

THE MANAGEMENT OF ROOM-PLANTS IN SUMMER.

FLOWERING-PLANTS kept constantly in a sitting-room are apt to become flaccid and weak, so that they fail to bring the bright blossoms which might otherwise be looked for in due season. The time has now arrived at which they are best out-of-doors, even delicate semi-tropical plants, such as *Arum Lilies*, *Orange-trees*, &c., being all the better for the invigorating effects of the outdoor air and the heavy dews of summer-time. A thick bed of ashes (sifted from the cinders of the house) laid down in front of a rather low north wall, which will allow of some vertical sunshine without baking the tender roots which cling to the pots, is an excellent place for room-plants in summer. If no such shelter as a wall be available, the pots should be sunk to the rim in fine ashes, which can be kept moist by copious watering in dry weather with a rosetted pot or syringe. Here *Azaleas*, *Ericas*, *Camellias*, *Rhododendrons* will form their flowers for next spring. *Lilacs*, too, of many kinds will bring their blossoms to perfection, being lifted into the drawing-room as they open, and returned to their out-of-door quarters when their flowers fade to slowly ripen their foliage and bulbs until the autumn, when they can be repotted. *Arum Lilies*, *Spiraea japonica*, and all spring bulbs, unless they can be put out into good garden soil for the summer to ripen, which is even better, can here store up strength for next season, being regularly applied with water, and given liquid-manure in a thin, clear state once a week, until their time for repotting arrives in autumn and they are again taken in. *Freesias*, too, having flowered in early spring, will stand here—looking very untidy with their drooping "grass," hanging about half-dead—until the end of July, when the neat little bulbs are ready for repotting, and can be planted (two or a dozen thickly in a 5-inch pot) in light, rich compost, and replaced on the ash-bed, where they will soon start into fresh life, and should flower about Christmas, being lifted into a warm sunny window at the end of September. *Ant-Roses*, looking drawn and weak from being long indoors, will here renew their strength, ripen their wood, and, perhaps, if mulched with good stuff, bring a few lovely autumn blooms; they should be pruned in November and potted at the same time, being allowed to stand out-of-doors until the first severe weather sets in, and given plenty of air and a sunny window. Then *Libonias*, too, well hardened in summer, will bring a mass of bright bloom in early spring, or even at Christmas, if placed in a warm greenhouse, and many another window-plant will renew its strength with plenty of open air. Regular and thorough watering must not, however, be forgotten, and the syringe freely used in the evening on *Azaleas*, *Chrysanthe-mums*, *Roses*, and, indeed, all the plants will keep off blights and induce strong growth. A rosetted watering-pot, where a syringe is not available, will make a fair substitute unless the plants are already infested with green-fly or thrips, when they should be dipped bodily into a solution of soft-soap, with the liquor of an ounce of shag Tobacco, boiled, mixed with it. This bath can be kept at hand for a week or two, and any plant on which blight can be discovered should be daily dipped for a week, washing off the soapy water an hour later with clean water, so as not to clog the pores of the leaves. After this thorough cleansing regular attention in watering and syringing should prevent a further attack.

J. L. R.

A new room plant (*Grevillea robusta* elegantissima).—This very beautiful variety of *Grevillea robusta* has much to recommend it for the decoration of rooms, for it combines the effect of a fine Fern with the robust growth of a small tree, which indeed it is—the "Silky Oak" of Australia. The leaves of the new variety are wonderfully finely serrated

and of a more drooping character than in the older *G. robusta*, so that the effect is still more like that of a handsome Fern. Seedling plants, raised in heat early in the year, can now be procured and grown on in small pots, with a light compost of leaf-mould and loam, until they are large enough for decorative purposes. This will need a sunny bow-window, without severe draughts, to bring them on quickly, although the little plants must, of course, be kept in a shady, cool place for a week or so after they are potted. As they become larger they will need another shift, but *Grevilleas* do best in rather small pots for their size, which are also the best for furnishing.—I. L. R.

Diplacus glutinosus for a window.—This plant is an old-fashioned favourite, but none the worse for that; in fact, it is a valuable room plant, its bright masses of apricot-coloured flowers being remarkably decorative. Although it is in reality a woody *Mimulus*, it can be cultivated very much as though it were a "*Geranium*"—i.e., repotted when necessary, giving the plant only a slight shift, and allowing it to rest during the winter months. Any ordinary potting compost will suit it, if it be well established. Cuttings, which can be taken at any time during the summer, should have light sandy soil, and be placed in a cool, shady

9 inches apart in good ground early in April, keeping them clean and well watered in dry weather.—J. C., *Byfleet*.

INDOOR PLANTS.

HYDRANGEAS AND THEIR CULTURE.

THOSE who live in distant parts of the country, on their first visit to Covent-garden-market, if such happens to be during the spring or early summer, see nothing that strikes them more forcibly than the numbers of *Hydrangeas* grown in small pots, not generally more than 6 inches or 7 inches in diameter. The plants grown to a single stem, 6 inches or 8 inches high, are furnished with three or four pairs of healthy leaves, surmounted by a globular head 12 inches or 15 inches through, generally of the freshest and clearest bright pink colour, although a few are met with possessing the blue shade that is so much prized by some, and for producing which there are several different recipes, in the shape of soil more or less impregnated with iron filings, charcoal, or slum, or pure peat. I have always found that if the plants were supplied with the large quantities of manure-water requisite to give size to the heads of flower, whatever the nature of the soil or ingredients added to it, the blooms

in which state they should be taken off at about the third joint below the bud, and inserted either singly in small pots or several round the side of a 6 inch one. Place a few bits of crocks in the bottom of each, on these a little fibrous material, and dry or flaky rotten dung, such as has been used for mulching a *Vitis* border or *Asparagus*-bed. They are in no way particular as to soil, but if it is preferred to have some of a blue shade and others the normal colour, a portion may be struck and grown in sandy peat and the others in loam, in both cases using it for the cuttings in something like a proportion of one-fourth sand to the loam or peat. The cuttings should be severed at a joint, and inserted firmly in the soil, the leaves, except those at the base, which must necessarily be removed, being retained. A slight hot-bed should be prepared, on which place an ordinary frame with glazed lights; in this plunge the pots, keeping them well moistened and shaded from the sun, but with the lights tilted night and day, so as to keep the tops cool, otherwise the heat will have a tendency to cause them to break into growth, and they would be spoilt for flowering in the dwarf state they are intended to assume. They will soon strike, after which the shading must be dispensed with, and when they are well furnished with roots at once remove them to 6-inch pots, in which they may be allowed to flower. Keep them quite cool through the autumn—any pit, frame, or house will answer, in which they will not get frozen—it is better not to subject them to frost; they will cast their leaves before winter, nothing remaining but the woody shoot with the bud at its extremity; but never allow the soil to become dry, or the roots will suffer. If desired, a portion of the plants may be had in bloom early by putting them in a moderate heat at Christmas, such as ainery or Peach-house at work, or anywhere where an intermediate temperature is kept up. Here they will soon commence growing, making two or three pairs of leaves below the flowers. As soon as they begin growing freely those that are intended to come with pink flowers may be assisted once a week with moderately strong manure-water, which will cause the production of much larger heads of bloom; but we have never been able to produce flowers of a decided blue colour if manure-water was used; when it has been given to them even when they were grown in all peat, or with slum or iron in the soil, they have come neither one thing nor the other, but a not very pleasing mixture of both. Such as are wanted later may be put in a little warmth, and some allowed to come on with the assistance of solar heat in an ordinary greenhouse temperature. So managed, a

A fine specimen of the Pink Hydrangea.

place for the first few weeks, when they will soon take root. Well-grown plants with plenty of wood should be potted (after cutting back the untidy sprays) in March, and covered with a balloon wire frame. If the young growth be trained as it grows to these wires (turning the plant constantly, so that it gets sunshine evenly on all sides), the effect, when in full bloom, is much better than when the plant is allowed to grow loosely, for its habit is not very neat, and the flowers thus trained show themselves remarkably well. When the plant goes out of bloom in autumn, it can be kept in a bedroom, or any place where the temperature does not go below freezing-point, being watered only when the surface soil is thoroughly dry; it must then be given sufficient water to run through the pot, when it will not need more for a week or two.—I. L. R.

4060.—**Marie Louise Violets.**—I should not advise you to grow these for profit in the open air unless you are exceptionally favoured as regards climate. Where fog prevails the flowers and buds are apt to be destroyed wholesale, and frequently the plants are killed. Lifted in October and planted in frames they are satisfactory. Heat is not required, unless protection from our cold, damp winter. The plants need well growing for winter blooming, putting out runners or pieces of divided plants

when fully matured, were pink of some shade. Larger specimens are grown for the London market bearing several heads of flower each, but for general decorative purposes the small plants with single heads are much the most to be preferred. In addition to the pleasing colour, general attractive character, and long endurance of the flowers, the plants possess the advantage that during the time they are in bloom they can be stood in places where there is comparatively little light, even under the shade of other plants, in positions that few if any other flowering subjects would bear without being so injured as to be useless afterwards. There is a

LARGER VARIETY of the common form, with the individual flowers of which the head is composed, as well as the head itself, much bigger than the other more generally known kind. This is the best to grow, differing in no way as to the treatment it requires in propagation, soil, and time of flowering. Cuttings will strike at any time of the year that they can be obtained in a half or three-parts ripened state, but to ensure the large heads on small plants, such as above described, the best method is to have a few plants grown out in an open, sunny situation, where they keep strong and short-cut. Those, according to the early or late character of each season, will generally get sufficiently matured to be taken off in August, at which time the buds will be formed in the points,

SUCKERS of flowers can be kept up for six months. If suckers are produced at the base these should be removed until the plants come into flower. After the blooms have got shabby the shoots that have borne them may be cut out at the bottom, as suckers are sure to spring that will make more compact plants; plunge them out-of-doors for the summer, winter out of the reach of frost, and in the spring, just as they show signs of beginning to grow, head them right down to the bottom. They will quickly throw up shoots that will produce large heads of bloom on much shorter growth than if borne upon the old wood formed the preceding year. I have kept plants for three years in the nine 6 inch pots they were first potted in without either change or addition of soil, simply by using manure-water during the time they were growing; in the second and third years they produced from three to half-a-dozen fine heads, showing what can be accomplished by the aid of liquid-manure to such plants as will bear it; in this case they may be said to have been altogether supported by it, as the small quantity of soil in which the roots were placed must, after the first year, have become so exhausted as to be nothing more than a medium through which the liquid sustenance was conveyed to them. For anything perceptible in the appearance of the plants as to vigour and ability to produce flowers, they would have gone on longer without change or addition of soil, but the experiment was cut short through unforeseen circumstances. If it is thought advisable to grow some on to a larger size, they should, when in bloom, be moved into pots proportionate to the size they are wanted to grow to, say 9 inches or 10 inches the first year; but for general use to produce plants to flower in a small state with single heads, nothing equals

the appearance of the autumn-struck cuttings that have been produced out-of-doors, for which the above two forms of *H. hortensis* are the best adapted. The variegated forms of *H. japonica*, *H. japonica argentea variegata*, and *H. japonica anrea variegata*, are well worth cultivation for the beauty of their leaves, as well as the flowers they produce. Varieties:

H. OKAKSA.—A very fine variety with large flowers, also suitable for pot-culture, like those already described, and of easy cultivation; it is propagated from half-ripe shoots and grown in ordinary soil, either peat or loam, with one-eighth sand, to keep such thirsty subjects from getting sour and water-logged; the plants should be exposed in the after part of summer in the open air to keep them dwarf and to get the wood ripened.

H. PANICULATA.—A white-flowered beautiful species that does well under pot-culture; it is a most profuse free-blooming plant, that deserves to be generally known and much more generally grown than it is.

H. STELLATA FLORE PLENA.—Another fine Japanese variety, producing very large corymbs of double rose-coloured flowers, and is in every way a desirable plant; treatment same as for the preceding.

H. THOMAS HOGG.—A very handsome kind that has appeared recently. It is a free-flowerer, producing moderate-sized heads of white flowers.

THE SYSTEM OF PROPAGATION and general treatment advised for the other species will also answer for these, except that where the plants are required to be grown to a considerable size they must be encouraged by more pot-room. With less trouble *Hydrangeas* may be

STRUCK FROM CUTTINGS produced in spring from plants that have been flowered early; these should be taken off when they have three or four joints, and put singly in 3-inch pots filled with half sand and loam. Stood in an intermediate heat, kept close, moist, and shaded, they will root in a few weeks, when give more air, and as soon as the pots are fairly filled with roots put in others from 6 inches to 8 inches in diameter, using good loam, well enriched with rotten manure and with some sand added. When well established in these move to the open air, and give water as required through the summer; keep in a pit or frame away from the frost during the winter until required for forcing, or in the greenhouse to come on with solar heat for later blooming.

HYDRANGEAS are not much troubled with insects, except green-fly, which can be kept under by fumigating, dipping, or syringing with Tobacco-water. B.

MUSSINDAS.

"J. B. H." sends a spray of *M. frondosa*, asking why this plant always makes white leaves along with its yellow flowers, and where it is from? Now, the white leaf spoken of is an enlarged bract of the calyx, and one bract only is developed with each flower. The plant comes from Ceylon, and I have heard it stated that these white bracts make a very refreshing salad when eaten between thin bread and butter; but as I have never taken them in this fashion I cannot recommend them from my own knowledge, but I can recommend these plants as very pretty objects for flowering in the stove. They belong to the order Rubiaceae, and are very easily grown treated as ordinary stove plants, potted in about equal parts of loam, leaf-mould, and peat, the whole well mixed and made sandy. After blooming they should be kept cool and comparatively dry for a time, then out back, and when the shoots begin to swell their eyes up, preparatory to beginning to grow, they require to be shaken out of the old soil and potted into a smaller pot, so that they can be shifted at a more convenient time, and be placed in the stove in a shady position, when they will form nice little bushes, which, after a time, will make the stove quite gay with their beautiful coloured bracts and flowers. There are several species known to science, but the three kinds named here are about all that are in cultivation at the present time. They are natives principally of India and Africa, but not of frequent occurrence in the Western world.

M. FRONDOSA, the kind sent, makes a handsome, compact plant, having moderate sized, dark-green, ovate leaves, which are thin in tex-

ture, and it produces terminal racemes of rich-yellow flowers, and an occasional flower has one segment of the calyx enlarged into a leafy bract of a pure white. Sometimes two bracts are developed from the same flower, but this is not frequent, and I do not remember to have seen it upon more than about three occasions in forty years. This plant is a native of Ceylon.

M. ERYTHROPHYLLA is a beautiful plant from the West Coast of Africa, for which, I think, we are indebted to Mr. Wm. Bull, of Chelsea. It is a much stronger grower than the last named kind; but it submits to the same treatment. The leaves are ovate and bright-green, covered with silky hairs, the flowers of a pale-yellow, furnished with large bracts of a charming scarlet hue.

M. LUTEOLA.—This is a plant from the region of the Upper Nile. I have had the plant growing once or twice, but I think it is still rare in our stoves. It is somewhat more slender in its growth than *M. frondosa*. The flowers are bright-yellow, deeper coloured in the centre, and it bears pure-white calyx leaves. J. J.

Diplacis glutinosus.—This native of California is a very useful plant for the greenhouse during the summer, as it will bloom continuously for months together, and its cultural requirements are of the simplest. There are several varieties in cultivation, all of which have the free-growing, free-flowering character of the type, but in some of them at least the bracts are more brightly coloured than in the ordinary form. The most notable in this respect are to be met with under the names of *aurantiacus*, *panicus*, and *Sunbeam*, while where seedlings are raised some individuals paler than the normal form often make their appearance, and occasionally a plant with nearly white bracts may be obtained. Cuttings can be readily struck at almost any period of the year, and those propagated in this way early in the spring will make neat flowering plants during the summer, while for larger specimens older plants may be employed. The genus *Diplacis* is now included in that of *Mimulus*, but it is so generally known under the first-mentioned name that it is not likely to be superseded in ordinary use. Though spoken of as a greenhouse plant, the *Diplacis* is hardy in some especially favoured districts, while where such is not the case it will both grow and flower well planted in the open border, and so treated the flowers are a good deal richer in colour than they are when produced under glass.—H.

4084.—The culture of *Stephanotis*.—This plant is best propagated by means of cuttings formed of the stubby side-shoots, taken off with a "heel," and inserted in pots of light sandy soil, plunged in a hot-bed in the spring or early summer. When sufficiently strong the plants should be set out in a well-drained bed of light rich soil, such as a mixture of loam, peat, leaf-mould, and sand, and if for early work in special it is a great advantage if the bed can be made over or close to several rows of hot-water piping, so that it may get thoroughly warmed through by the time the plants begin to grow. Keep cool (45 degs. to 50 degs.) during the early part of the winter, or while at rest, and when the fresh growth commences maintain a regular temperature of 65 degs. to 80 degs., and syringe the plants frequently and heavily. Plenty of water and some weak liquid-manure once a week are also required by plants in full growth and bloom, and shade from hot sun must be given. Another important point is to keep the growth free from insects, particularly scale and mealy-bug, by sponging the foliage with some good insecticide as often as may be necessary. Plants can be obtained of any good trade grower, but take care to obtain the true free-flowering variety; the price for small plants would be about £5 per 100. But this number would suffice for more than an acre of glasshouses, as a single plant will fill a structure say 50 feet by 12 feet in the course of a few years.—B. C. R.

—The *Stephanotis* is easily propagated from cuttings of the young wood in a close, warm, shaded hot-bed. The culture on a large scale implies the possession of a long range of greenhouses. You will hardly require a heated plants; half-a-dozen plants will if planted out in a well-drained bed of peat, loam, and leaf-mould, soon furnish a large house. The

best way to get the plants to flower well is to train the shoots on wires from 6 inches to 9 inches from the glass. The night temperature should never fall much below 60 degs. This plant is usually grown in connection with other plants in pots, or Ferns, &c., the *Stephanotis* occupying the roof and the other plants beneath. The plant is very subject to mealy-bug, therefore it is very important to get the plants from a clean source, if possible, and watch them very closely at first. When this pest is introduced it will be an everlasting job to get rid of it again. Good plants will not cost less than 3s. 6d. each.—E. H.

I should say that to purchase *Stephanotis* plants by the hundred is rather a large order. Anyway, the fact that you think so many plants are necessary to start with shows that you have forgotten your business, if you ever knew it. When you come to realise that an area of 50 square feet is quickly covered by a vigorous plant you will understand that a much smaller number than you mention will be sufficient, unless you are going to cover a quarter of an acre of ground with glass. You had better purchase healthy young plants at about 3s. 6d. each, and having once got a stock you will not want to propagate for several years. If I was going to grow this plant in the way you suggest, I should erect a bench over the hot-water pipes along each side of a span-roof house, and place a bed of soil about 6 inches thick upon it, increasing the depth by surface dressing of about 2 inches every year; but I would not make up the bed of soil the whole length at first, only at intervals of, say, every 8 feet, and then put in the plant, increasing the length of border as the roots extend. Half turfy loam and half peat is a suitable soil for this plant. It is so well that you should know that although the *Stephanotis* will do well in a high temperature during the winter, it can be safely kept through that part of the year in a temperature of 50 degs., and plants treated in this way will produce more flowers, only not so early as those which have more heat. You, of course, are aware that keeping up a high temperature during the dark days of mid-winter means a considerable outlay for fuel. You must keep the young growth well separated, or it will not get sufficiently hard to produce flowers.—J. C. C.

4085.—Ailing *Fuchsias*.—From the description given I should say that your plants are infested with red-spider, which is generally the result of drought at the roots and a want of fresh air and moisture atmospherically. The best remedy is to thoroughly soak the roots with clean water and syringe the plants well both on the under-side of the leaves as well as on the top with clear water, adding a handful of sulphur to a 3-gallon can, adding also a knob of soft-soap of the size of a Walnut to each canful of water. Directly a change in the colour of the leaves is discernible supply the roots freely with weak liquid-manure with a view to stimulating the growth.—S. P.

—The signs are those of red-spider. Lay the plants on their sides, and syringe with soft-soap and water, 3 can of soap to the gallon of water, applied warm. Afterwards syringe with clean water, and to future, as long as the hot weather lasts, syringe daily and give enough water at the roots. A little stimulant in the water will be beneficial.—E. H.

—No doubt the plants are suffering from an attack of red-spider. Lay them on their sides on a bit of Grass, and syringe the under-sides of the leaves well with Tobacco-water, or a mixture of water, soft-soap, and paraffin will answer the purpose equally well. Syringe with clean water subsequently, and repeat the process once or twice at intervals of a few days, if necessary.—B. C. R.

4088.—*Fuchsias* for a trellis.—Several varieties are adapted for this culture, and it is a pity that the *Fuchsia* as a climbing plant is not more thought of in gardens. It seems to have fallen from its once high estate. A few *Fuchsias* draping pillar, post, or trellis with their gay flowers is a pretty picture. You want to get the stronger growing kinds, and a very charming variety for the purpose is *Rose of Castile*, which have a large corolla, purple in colour, and the habit of the plant is robust. *Marquis of Bristol* (scarlet) and *Alexandra* are also two fine kinds, the latter having petals of a crimson colour, the corolla white. Worthy of mention are the well-named *gracilis*, sometimes called *frutescens*, which is exceptionally free, very slender flowers, produced with great freedom, and crimson in colour. *Monarch* is conspicuous for its very large flowers, the colour bright red, and Gen. Roberts, the segments crimson, and

corolla violet, is another good variety. These are all of note, and though they are old varieties, they are none the worse for that. I have looked through several catalogues, and notice that they are included, so that you will have no difficulty in getting them.—C. T.

— The best Fuchsia for your purpose is the Earl of Beaconsfield. Either planted out in a border or in a large box, this will speedily run up and cover your trellis with lovely blooms.—A. G. BUTLER.

COTTAGE GARDENS.

This pretty picture of a cottage garden is one of an old-fashioned kind, and such as may be found in some parts of the country. Such a place as this, though the variety of flowers is not great, is far more pleasing than many more pretentious gardens, and there is a charm in the irregular crowded border near the house and the climber-clad walls which may be sought in vain in the prim parterre. These cottage gardens, with their wealth of bloom and foliage, form one of the chief attractions of a country walk, and no good gardener is ever above taking useful hints from them.

TREES AND SHRUBS.

4049.—Hardy Azaleas.— I am pleased to answer a query about hardy Azaleas, for they are shrubs much neglected in English gardens, although of great beauty. This query affords opportunity to make reference to this beautiful class of shrub, which fills the garden with colour in the late days of May or early June, and in the autumn the leafage puts on brilliant shades of crimson and bronze. The hardy Azaleas are amongst the most beautiful things that can be used for the garden, where there is sufficient space for them; but they are more suitable for the woodland, or to form bold groups on the outskirts of the lawn. As full information is asked for concerning this class, I may mention, firstly, that they are not difficult to grow with success. For many years Anthony Waterer, the well-known nurseryman at Knap-hill, Woking, has been raising varieties which improve annually until a race called the "Knap-hill" has been raised up, which represents the hardy Azalea in its finest phase. These shrubs offer great variety of colour in the flowers, which vary from pure white through brilliant shades of carmine, scarlet, orange-scarlet, and yellow, in many tones melting one into the other. Yet, strange to say, they are not used freely in English gardens, although hardy, and so sweetly scented that a group in full bloom sends a sweet odour into the garden—a pleasant, spicy scent peculiarly agreeable. The first beginnings of the race, so to say, were made when the North American species, such as *A. calendulacea*, *A. nudiflorum*, and *A. pontica* were intercrossed, and the foundation laid for the beautiful kinds one sees at present in gardens. So free-blooming are they that even very small plants are smothered with flowers, the little bushes a mass of bloom, and their beauty increases with age. The whole aspect of the shrub is pleasing, with its tier-like arrangement of the branches and remarkable freedom. In the more recent acquisitions one gets flowers of great breadth, the upper petals broad, thrown well back, to show up the resplendent colouring, a very marked difference to the old type, which had small flowers, cramped, and without the breadth of those of later years. Very few varieties are

named, and it is wise policy, as the race in general is distinguished by superb kinds, but a few have distinctive titles, such as Nancy Waterer, a broad, rich golden flower; and Mrs. Anthony Waterer, a very lovely variety, the flowers produced in an even compact truss, and individually pure white, except a suffusion of soft yellow on the upper segments, and very fragrant. This represents a superb type of hardy Azalea, and justifies a name. To show how slow is this raising of new kinds I may mention that quite four years elapse before the seedlings bloom; then they have to undergo careful selection, many, of course, failing to come up to the requisite standard of excellence.

masses of them in early summer, and then we get the fine colours of the leaves in autumn. As regards culture, much the same conditions that agree with the Rhododendron are also favourable for the Azalea. If you have a wild, woodland spot that requires lighting up with colour, you cannot do better than plant in groups, and they need shelter from the winds, which surrounding things will provide. There is also less risk of injury from frosts, whilst another desirable thing is shade, not dense, but a little protection from the fierce and continual glare of summer sun. The best soil, as for the Rhododendron, is peat, but good fibry loam will suffice, or loam and leaf mould mixed. There is no doubt that in the near future the Azalea will take the place, to some extent, of the Rhododendron, although I have nothing to say against this noble shrub. But it is overdone in gardens, and when this is the case, no matter how beautiful the subject is, it loses in interest, producing a monotonous effect.—C. T.

4087.—Striking cuttings of shrubs.— Cuttings of Deutzias may be struck in two distinct ways: (1), by inserting the young shoots, about 3 inches long, with a "heel," in well-drained pots of sandy soil in the spring, keeping them close, warm, moist, and shaded until rooted; and (2) by employing pieces of the mature wood of the current season in the autumn, placing them rather thickly in any sandy soil in a cool greenhouse or frame. Cuttings of Escallonia and other choice evergreen shrubs should be inserted in sandy soil in the autumn, placing them under hand-lights or a frame; if they can have a gentle bottom heat in the spring, after the cuttings have "callused," so much the better. Cuttings of Weigela, Syringa (Philadelphus), the Snowdrop-tree (*Halesia tetrapetala*), Veronicas, Hydrangeas, Spiraeas, and many others may be rooted in the same way.—B. C. R.

— Escallonia and Deutzias will strike now or till the end of October under a hand-light, kept close except for about an hour in the morning, when a little air should be given. The soil should be kept moist by giving a sprinkling as often as is necessary. All evergreens will strike during the next three months under the conditions named; but, for the most part, deciduous shrubs had better be left till the leaves fall. A few good evergreen shrubs of which cuttings may be taken are the following: *Kuonimys* in variety, *Aucuba* in variety, various kinds of Laurels, Box, Ivica, and most of the Conifers may be rooted from cuttings, though any plants which produce seeds freely had better be raised from seeds. The various forms of Evergreen Berberry, for instance, produce

OUR READERS' ILLUSTRATIONS: Cottage at Beshington, Somerset. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. W. Thompson.

These are eliminated. Yellow is a prevailing, but there are now many beautiful scarlets that seem to glow like a tongue of flame when amongst shrubs. Then you may get some double kinds, which represent a departure that is rapidly being improved upon. Here, again, one sees various colours, and the flowers of charming shape, each like a little rosette, and precious for cutting, not only for their colour and long-lasting qualities, but also for the sweet odour. The pink-coloured kinds are very pretty in a vase loosely arranged. The later-blooming hybrids are being added to each year, and we shall, I think, get a race that will carry on Azalea time until quite the summer. There is beauty in these shrubs throughout the year, the growth spreading and picturesque, the flowers abundant,

and may be raised in that way, though the common varieties of Berberry may generally be increased by division of the underground stems, where only a few plants are wanted. The propagation of trees and shrubs is rather a large business. Though most of them may be rooted from cuttings, there are certain kinds that will root with more certainty, and in less time, if the shoots near the ground are layered; for instance, Rhododendrons, Kalmias, Wisterias, Magnolias, Daphnes, Laurustinus, and Cydonias are best layered. On the other hand, Jasmines, Forsythias, Ribes, Philadelphus, Spiraeas, and Weigelas will strike freely from cuttings of well-repined wood planted firmly underground, provided that careful attention is given in the matters of watering and shading.—E. H.

ROSES.

NOTES ON TOWN ROSES.

IN GARDENING, June 10th, 1893, page 201, a note appeared on town Roses, but to what was there said a few more notes may be added. A friend who grows Roses well within the influence of London smoke has given me the following information as well about them. Many of the dwellers in crowded towns try to grow Roses, wishing to bring fragrance and beauty into their crowded gardens. The culture of the Rose under such circumstances is beset with difficulties, and in the midst of smoky cities the task is not encouraging. One has only to see the subject misery depicted on the plants in the public parks, where every care is taken to give them the best attention, but it is pure air that they require, a thing that unfortunately cannot be artificially supplied. Sunshine and air, these are the two essentials, and with an abundance of each the growth gets well ripened, a point of great importance. Sappy, badly ripened shoots will never bear good flowers, and they suffer severely from winter frosts. Draughts that torture the plants in small gardens, withering them up, and driving out fresh, buxom health, are fatal to the Rose, and if the ground is filled with tree-roots success can never be expected. Soil, if poor, or flavoured with the leakings from gas-pipes, will not suit the plants, and when bad must be made good by getting in new material. If moderately good, it will only be necessary to incorporate with it a liberal dressing of cow-manure. In the case of new gardens trench up the soil thoroughly at first, dress liberally with cow-manure, and expose the beds to the air for a time, so that rains and frosts may act upon the material and sweeten it. Planting can only be done in one way, but prune less evenly than for country-grown plants. Many of the fine old pillar Roses that are so beautiful in large English country domains are very useful for planting near towns, and their robust growth adapts them well to resist the troubles of town life. One secret of success is to always choose plants of vigorous growth, and a few varieties of the Hybrid Perpetual class especially suitable are: Abel Grande, Alfred Colomb, Baronesse Rothschild, Charles Lohve, Duke of Edinburgh, Beauty of Waltham, Dr. Andry, Camille Bernardin, Mrs. John Laing, the beautiful General Jacqueminot, or "Jack," as it is called in the market, Senatour Vaisso, Louis Van Houtte, Magna Charta, John Hopper, Duo de Rohan, Crimson Bedder, Reine Marie Henriette. This is an interesting selection, and amongst climbers very beautiful are the old Gloire de Dijon and Mme. Bérard, both of which may be expected to thrive, whilst those who care for a larger list may have the old Lamarque, Aimée Vibert, Fielded Perpetuals, Compe d'Hébe, and Rampart. It would not be advisable to indulge in many Tea-scented varieties, except Grace Darling, Mme. Lambert, Catherine Mermet, and Marie Vae Houtte, which I have seen very beautiful near large cities. V. C.

Gloire de Dijon Rose—I always look through the pages of GARDENING ILLUSTRATED, partly because I find its instructions simple and accurate (as a rule), and chiefly because I rejoice to know that a multitude of working men are reading it simultaneously sitting restfully at their cottage doors, smoking in their gardens, and then, it may be, gardening in their smoke. But there is no rule without its exception, and I am perturbed to read, at page 229 of this week's publication: "I do not think the Gloire de Dijon Rose worthy of so much space under glass. There are so many better ones." I have grown Roses, enthusiastically and extensively, under glass and in the open ground, for half a century, and I am confident that for abundance of beautiful blooms, early (very early) in spring, and late (very late) in autumn, there is no Rose so reliable as Gloire de Dijon. It filled a good-sized greenhouse at Taunton, and, like its sister on the south wall of the church, produced hundreds of its lovely flowers. I am, therefore, at a loss to know how the space could have been more worthily occupied, and what are the names of the many better sorts referred to by "J. C. C."—S. REYNOLDS HOLE.

4093.—**Early Roses**.—Does the first part of your question refer to Roses that are to be

grown under glass? It appears so from the latter part of your inquiry. If that is so you will find Tea Roses the most suitable, and very good ones for your purpose are Luciole, Anna Olivier, Perle de Lyon, Innocente Pirola, Marie Van Houtte, Grace Darling, The Bride, Catherine Mermet, Comtesse de Nadaillou, and Mme. Lambert. The plants, if large ones, should be pruned into shape now, and given larger pots if they want them, and have all the flower buds picked off until the end of September. If they are placed in an increasing temperature about the beginning of the new year they will flower in from eight to ten weeks. The same varieties would do for planting in the open air if your garden is not too much exposed for this class of Roses. I would, however, rather depend upon the Hybrid Perpetuals. For your purpose the following are suitable; Alfred Colomb, Crown Prince, Doctor Andry, Dupuy Jamin, Jules Margottin, Gloire Lyonnaise, Louise Darzins, Mme. Gabriel Luizet, Mrs. J. Laing, Miss Hassard, and Duke of Teck.—J. C. C.

4096.—**Roses not thriving**.—That some of the hardy Tea Roses should do better with you than the Hybrid Perpetuals will be read with some amount of credulity by some people. The reason, however, is explained in the information you send when describing the soil. The H.P.'s do not like a dry and poor root-run, especially when they are growing on foster roots, but it will suit the Teas better. I advise you to try a few more of the latter; the varieties may include Marie Van Houtte, Anna Olivier, Mms. Lambert, Perle de Lyon, Saffron, The Bride, Grace Darling, and Viscountess Folkestone, and I believe some of the strong-growing H.P.'s will thrive on their own roots in such a soil. I would select such varieties as Alfred Colomb, Magna Charta, Ulrich Brunner, Mme. Naohury, Captain Christy, Charles Lohve, Earl Dufferin, Mrs. J. Laing, Mme. Gabriel Luizet, John Hopper, and Fraçois Michéol. Unfortunately, these are not all suitable as button-hole Roses. Some of the Moss Roses are very hardy, and would thrive with you as dwarf plants. The common pink variety and the White Provence are very suitable for your purpose, and so are the China Roses. The old Pink Monthly is not to be despised when more tender ones fail; then there is Cranolie-Supérieure (rich-crimson), Fabvier (scarlet), and Prince Charles (cherry-red). Quon of Bedders and Bourbon Queen amongst the Barbons are both reliable Roses. Some useful early-flowering yellows, double and single, will be found in the Austrian Briers, so that you will see there is no reason whatever why you should be without Roses, and you will notice that I have not burdened you with a long list of varieties.—J. C. C.

—On such soil as yours the only way to succeed is to trench the ground deeply—3 feet, if possible—to manure it heavily, and give plenty of water, and a thick mulch of manure over the beds in hot, dry weather. I do not know of any varieties especially suitable for such a dry position, but should choose the more vigorous growers. Gen. Jacqueminot ought to do well; also Victor Verdier, La Fraee, Baroness Rothschild, &c., and the more robust Tea-scented kinds. Plants on the Manetti stock will be most likely to thrive.—B. C. R.

The Cardinal flower.—A very beautiful class of Lobelias is that known as the Cardinal flower, of which *L. fulgens* is an excellent type. *L. fulgens*, Queen Victoria, and Firefly are remarkably effective, the foliage almost chocolate in colour, and the flowers intense crimson, a decided contrast. Moisture is their chief requirement. The plants will live almost in water, and if there is a boggy bit of ground, or a streamside where the Marsh Marigolds exalt their golden flowers, the Cardinal Lobelias also will lift up their strong, erect spikes. In the southern districts of England they may be left out through the winter, but if there is any doubt concerning their hardiness in the particular position lift them and plant in a common cold frame, protecting with mats in the event of exceptionally severe weather. A bed or clump of the Cardinal flower with the surface covered with White Tufted Pansies is a charming picture. The surface of the bed may also be enriched with other things, and Mignonette is useful for the purpose. This type of Lobelia

blooms later in the year than many bedders, and if the garden is of large size a good group of it is intensely rich, the flowers rich-crimson, splendidly set off by the deeply-coloured leafage.—C. T.

FERNS.

SELECT ADIANTUMS.

MAIDEN-HAIR FERNS are always admired, and it is no wonder that they are favourites, for all are exceedingly beautiful, and all are useful in a hot estate, although some may be used with more advantage than others. *A. cucullatum* is frequently called "the Maiden-hair Fern," although we have upwards of 100 described kinds, and more than one-half that number in cultivation, yet Kew is one of the only places where a collection of kinds can be seen together. In these days of Fern revival I am under the impression that it is a want of knowledge of the kinds to enquire for that is one of the chief stumbling-blocks to their more extensive cultivation, and I therefore introduce to my readers a few of the more choice kinds, and amongst these the subject of the illustration on page 279.

A. FARLEYENSE, must ever stand prominent. The history of this plant is somewhat obscure, but I think it was in the year 1843 that the plant was shown at the International Exhibition, the only international show, by the way, ever held in England by the Horticultural Society, whilst in Belgium a fine exhibition is held every five years, and the society is flourishing. This beautiful Adiantum was first shown by the Messrs. Veitch, of Chelsea. It was introduced from Barbadoes. Curiously enough, I believe the plant has always been barren, or, at least, I have never seen a fertile state of the plant, and I have had many thousands through my hands, and have seen the plant in many hundreds of gardens; this fact has led to the supposition of its being a hybrid form of *A. teesdallii*, but be it sport or hybrid, it is the most beautiful Maiden-hair which has yet been found. A description of the plant is quite unnecessary with such an illustration. Suffice it to say that it is a plant which revels in strong heat and bright light, and a fair amount of sunshine. Indeed, it requires a much greater amount of the latter than the majority of Ferns, as if heavily shaded it comes weak. Another peculiarity is that it should not be allowed to get larger than the plant shown in the illustration, as the fronds are apt to decrease in size, and I may say that I have always seen the largest and most beautiful fronds upon small plants. The plants thrive best when the soil consists of fully half light turfy loam. *A. cucullatum* is one of the most beautiful of basket Ferns; the fronds are somewhat erect, but beautifully curved, and I have only seen this plant non-productive at the points when it has been grown in too dry an atmosphere to allow the young buds to develop. I have had a specimen of this species with nearly a hundred fronds upon the one plant, and these were each upwards of 18 inches long, and easily all viviparous at the apex. It requires stove warmth. *A. cucullatum* is another very pretty plant, which is a native of marly banks and dry places by the seaside on the Island of Jamaica. It is frequently found as a simply pinnate plant, and again with but a pair of short side brachies at the base, but I also have it with two pairs of branches at the base. The fronds vary from 9 inches to 18 inches high, with jet black stems and rich deep-green pinnae. *A. cristatum* is another magnificent plant, but yet it is one that is seldom seen in good condition. The fronds on a well-grown specimen are each from 2 feet to 3 feet long. It appears to be somewhat plentiful in Jamaica. *A. curvatum*: No more beautiful Fern exists than this species when well grown, but a well-developed specimen is rarely seen. The fronds are each some 18 inches or 2 feet high, and a foot or more broad. It enjoys shade and likes to be kept somewhat dry.

A. BOLABRYFORME is another basket kind, which grows freely in a warm moist stove; in growth it much resembles *A. lunulatum*, but the pinnae are much larger, and its fronds are permanent and do not die down in the winter months. They are also viviparous at the points, and form a pretty mass of young plants. *A. Edgeworthii* is a plant which botanically is said to be the same as *A. caudatum*, but is, however, sufficiently distinct as a

garden plant to require a separate name; it has the habit of *candatum*, and is very prolific in forming young plants at the points of the fronds; the pinnae, however, are somewhat different in shape, less villous, and consequently deeper and brighter green in colour. *A. digitatum* is a very pretty plant, belonging to the scandent group. It has fronds each from 3 inches to 4 inches or more high, and about three times divided, the stems being black and shining. *A. Feei* is another climbing variety, better known perhaps by the name of *A. flexuosum*, which was given it by Sir William Hooker on account of the zigzag rachis; its fronds are each several feet in length. The pinnules when barren are deeply toothed, but when fertile they are deeply reflexed all round. *A. fragile*: In this we have a dwarf and pretty tufted species, somewhat resembling a small form of *A. venustum*, and of just such a glaucous hue. It has, however, a peculiar character, in that the pinnae are jointed to the top of stipes, so that in the event of the plant becoming dry the whole of the pinnules fall away, leaving nothing but bare stems. It is found in Jamaica, growing on chalky rocks. *A. Henslowianum* is a beautiful

fen-shaped, and bright-green. *A. Williamsi* (the golden Maiden-hair) should not be absent from any collection; its fronds are tall and the pinnules small. The basal part of the stem is clothed with a golden farina, and a little of this is also dusted over the underside of the pinnules, whilst the length of the fronds, coupled with their hardy character, renders them very suitable for using in table glasses with cut flowers. Other choice kinds of noble growth are *A. peruvianum*, *velutinum*, and *subcordatum*, whilst such kinds as *A. polyphyllum*, *trapeziforme*, *tetraphyllum*, *pulverulentum*, &c., although more frequently seen, are yet not nearly so largely grown as they deserve to be, and even the many small-growing kinds, such as *A. tinetum*, *bellum*, *Pacotti*, *Veitobi*, and a host of others could be easily grown in private gardens in place of having so many plants of the old and very beautiful *A. cuneatum*. O.

4016.—**Show Ferns.**—Presuming exotic varieties are meant, the following are not only choice, but quickly form handsome specimens if well attended to: *Adiantum Farleyense*, *Gleichenia pinnosa*, *Microlepia bieta cristata*, *Nephrolepis Davalloides furcata*, *Davallia Mooreana*, and *Cyathea dealbata*.—S. P.

quite herdy in the open—at least, in all the more southern counties of England—comprising *F. coccinea*, *F. Riccartoni*, *F. globosa*, *F. gracilis*, and others, chief among these being *F. Riccartoni*. It produces a wealth of crimson pendent flowers. If *Fuchsias* are left out in the open during the winter it is always wise to cover the crowns with coal-ashes.—V. C.

THE KITCHEN GARDEN.

NOTES ON CUCUMBER CULTURE.

It is not my intention to enter fully into the details of the cultivation of Cucumbers, but rather to make a few remarks in connection therewith, as I find there are differences of opinion upon various points. Amongst these the question of ventilation *et cetera* non-ventilation may require some explanation, as I find that people, especially those who are young growers, are apt to rush to extremes. To guard against extremes, and as a safe practice, it has been advised not to ventilate at all, but to allow the temperature to rise as high as it likes from sun-heat, this being counteracted by the temperature being continually kept at saturation point through abundance of moisture in the atmosphere and also over the foliage. During the heat of the summer the rays of the sun are slightly broken by a light shade, such, for instance, as a little flour and water syringed over the roof. I do not dispute that plenty of Cucumbers have not been produced under this non-ventilation system, but I prefer to take the testimony of one of the largest market growers in the county that the system is not worthy of imitation, as abundance of Cucumbers may be produced under the ventilation system when used judiciously. For private use I am certain that ventilation, when applied judiciously, is the best system to pursue, so as to keep up a steady supply of fruit. We do not want Cucumbers by the score, and then a falling off to almost *nil*, but sufficient to meet the daily wants.

VENTILATION is often sadly misused during the winter or even early spring months. The time honoured chink of air I am no believer in, merely for the sake of putting it on for a change of air, whether the external conditions are suitable or not. In my opinion the best plan to pursue is to put on ventilation whenever conditions are favourable. Any

person when acquainted with the structure can tell directly he enters whether ventilation is needed or not. During mild weather from spring onwards during the summer months I like to put on a little ventilation at the apex of the roof at 6 a.m. At this time there is not such a vast difference between the inside and outside temperature, and air put on at this time keeps the temperature from reaching unduly high. It is certainly very misguided practice to allow the temperature to rise considerably before putting on air, but this is often done. Whatever ventilation is now put on will not counteract the evil; consequently the foliage very quickly has a parched appearance. With the ventilation early applied such an unsatisfactory state of things would be avoided. In some structures not so fully exposed as others such ill effects may not be noted, but in those facing due south they certainly happen. Next to ventilation, I think the

STOPPING and thinning out of the shoots are the most abused. During the most reasonable weather growth takes place very rapidly, and if thinning is not taken in hand, the crowded growths are almost impenetrable, mildew under such circumstances being asserting itself. It is

Adiantum Farleyense. [See page 278.]

erect-growing plant, with fronds some 18 inches or 2 feet high. *A. macrophyllum* is a beautiful plant with large pinnae, arranged in pairs on a jet-black stem, the barren pinnules being about 3 inches long and 2 inches broad; when young of a rich bright-pink, changing with age to deep green, the fertile ones narrower. We have now a form of this plant called *bipinnatum*, having a pair of side branches at the base; this adds materially to the effect. I recently received from the Messrs. Rogers, nurserymen, of Lodsworth, Sussex, a beautiful form with streaks of white variegation, for which I cannot suggest a better name than *albostriatum*; it will become a marked beauty in a collection, and it is not likely to run out of character, as the Messrs. Rogers tell me they have had the plant eleven years, and it has always maintained its character, having raised it from a spore. *A. monoclamyis* is a small-growing Japanese form, which grows on the hill-sides in the Straits of Korea. It is easily distinguished by the large and bold single sort set in a deep sinus on the top of the pinnules. *Appalachium* is another fine species, with very long fronds, which are about twice divided, the pinnules being large,

A note on Fuchsias—I am pleased to see that the *Fuchsia* is becoming more largely grown for beds, and those who have hitherto failed with it out-of-doors should remember that the great point is to get the growth well hardened, then a display of bloom will appear early in the summer, lasting until quite the end of the season. It is so easy to propagate the *Fuchsia* by cuttings, that the merest novice may succeed. Strike them in the spring, first placing a few old plants in gentle warmth, and take the little stubby side shoots, which form roots quickly if placed in a light soil in 5 inch pots, stand them on a mild hot-bed, and when struck pot on into larger pots, using much the same kind of soil. When of sufficient size, say in 48 inch pots, they may be planted out, either in beds or baskets. The finest results are always got from old specimens that have ceased to become of much value in the plant house. Always get the growth well hardened, not forcing it in any way, as the more shoots formed purely in the open air the better the display of flowers. Strong shoots selected from these are, here in the autumn will make excellent plants, taking care to keep the soil moderately dry during the winter. There are a few kinds

the same with Cucumbers as other fruit-bearing subjects—direct light is needed to form a solidified and fruitful growth. Often certainly Cucumbers form freely, but instead of coming to maturity they all damp off. The stopping of the shoots must have early and frequent attention when once the framework of the plant is laid. With some people at this stage it is the practice to stop at the second leaf, or what is termed a joint beyond the fruit. I hold that such a course of procedure fills up the space with a lot of useless growth, and that it is far better to stop the shoots at every leaf throughout the spring and summer months. It is also a good practice to remove the larger leaves by degrees, laying in younger growths to fill up the space, as by this means the plants are kept more under control and are not so likely to quickly become exhausted. One of the main causes of exhaustion is overcropping. For private use, where only a steady supply is needed, it is a mistake to allow all the fruits which form to remain. The wisest course will be to cut off all except what are needed for the crop, leaving them in various stages, as by working on this system the plants keep longer in bearing. The market grower, again, directly it is seen that the supply is failing, clears out the plants and makes a fresh start. In a private garden this mode of procedure is not very convenient. Coming to what I may term

"FEEDING" the plants, this is the shent anchor, as it were. Unless this is rigidly adhered to, the plants cannot be expected to carry presentable fruit or to remain in health very long, for most surely insects innumerable will attack them, besides mildew, and the fruits will turn yellow at the ends instead of swelling away freely. I have often heard growers complaining of the fruit turning yellow, and most surely the source has been traced to either dryness or want of fertility in the soil. Often overdryness may be attributed to the action of bottom-heat pipes through the soil being placed in almost close contact, excepting, perhaps, a few bricks ends between. My practice is to place a layer of well-worked fermenting material, to the depth of about a foot after it has been heated firmly, over the bricks and before placing on the soil. This counteracts the dryness which is likely to accrue were such material not present, while it also forms a very congenial bottom for the roots. Whenever water is applied, sufficient should be given to soak the whole mass, mere surface dribbles being of no use whatever. Neither should other than tepid water be given, as obviously the roots would be in danger of being chilled if cold water was used. One of the main points in the cultivation of Cucumbers is to encourage surface feeders, and this is best done by giving an occasional surface-dressing of rich compost. This, if kept moist, will encourage surface roots. For what I may term regular feeding, I am very partial to manure-water made from fresh cow-manure and cast. This must be applied in a diluted and clear state. This latter is a particular point to take note of, for if applied too freely the rooting medium would become soured and the plants would very quickly have a sickly look. When the structure is closed in the evening of fine days, it will also be an advantage to damp the floor with liquid, this proving of marked benefit by charging the atmosphere with ammonia. A.

4090.—**Unhealthy Cucumbers.**—They have been planted, I should say, in something they do not like in the first place, and this has been aggravated since by improper treatment; but it is impossible to say when that improper treatment is, because no information is given. They may have had too much or too little water, or too much shade, or the pinching and stopping left in arrears—and if the growth gets too crowded the foliage soon goes wrong. Mildew may have been in the frame, and this may account for the dark spots on the middle of the leaves. The best treatment now will be to thin out well. Top-dress with rich compost; at the same time ascertain the condition of the roots as regards moisture. Shade on bright days from 10 a.m. till 3 p.m., then sprinkle and close. Open the frame just a little in the morning by seven o'clock, increasing the ventilation according to the temperature. —E. H.

AUTUMN GIANT CAULIFLOWER.

WHAT AN important market vegetable this fine Cauliflower has become is well shown in various parts of Kent, where large breadths of it are planted. Large quantities of it are grown for pickling. To have specially good white heads it is a good plan to tie up the leaves, as in the case of Lettuces, so soon as the flower-heads begin to show. A.

4091.—**Tomatoes dropping their buds.**—The Tomatoes you name are all good setters, so there must be something wrong in the management; either they do not get ventilation enough, or they need more support. In this dry, scorching weather, Tomatoes want a good deal of water. It would be well to mulch with short manure, and give a thorough soaking of water, not a mere sprinkle, and give more ventilation; leave a little air on all night.—E. H.

—This must be put down to the intense heat and drought; this is plainly proved by the beneficial effects of syringing, and possibly if you were to syringe the plants still more heavily they would do better still. I find much the same thing myself; when we get two or three comparatively cool days the fruit sets right

Cauliflower "Autumn Giant."

enough, but during the bursts of tropical heat that have occurred lately numbers of the blossoms drop, in spite of every care. When the drainage is good you may keep on watering Tomatoes under glass nearly all day long in such weather as this—in fact, the difficulty is to give them enough. See that the border is moist right through to the bottom. Those mentioned are three of the best setters in cultivation, and you may be sure that if they fail no others are likely to do any better.—B. C. R.

—When the flowers of Tomatoes fail to set their fruit in such a favourable season as the present one, it is very plain that the management is at fault. In this case I believe it is further aggravated by the soil being too loose. When potting or planting out Tomatoes the soil should be fairly dry and well rammed or trod. I have a capital set of fruit, both indoors and out, and never had it finer. The plants in pots and boxes have been watered twice a day all through the past hot weather, and the plants trained to a wall in the open and others in the open border have been regularly watered every day for the past two months. During that time my houses have had a little air left on all night, all the ventilators being opened at 6.30 a.m. and not closed again until 8 p.m. I have no faith in syringing Tomatoes; as a matter of fact, if a flower is dissected it will be seen that it is impossible for the water to reach the pollen, therefore it cannot assist in its distribution. Well on the soil when the surface is dry, and give more water.—J. C. C.

BRUSSELS SPROUTS.

In an article under the above heading (page 152), "A." remarks: "Why people will persist in setting out their Brussels Sprouts between rows of Potatoes I cannot imagine." May I inform the writer why I do the same thing and have done so many years? It is because I believe that in getting two crops in a year instead of one from a piece of land I am augmenting the sum of the produce from the same piece of land, although the quality of the produce might not be so fine as where only one crop is grown in the same time. I have at the present time a quantity of Brussels Sprouts growing between rows of Potatoes that are looking exceedingly well. The rows of Potatoes (the White Hebron) are each 4 feet apart. I have a thick mulching around the Brussels Sprouts, and they have been watered two or three times. I have some planted between rows of Potatoes 3 feet apart, and also some between rows 2 feet apart. I regulate the distance between the rows of Potatoes according to the strength of the haulm produced by the variety. In the instance where the rows are 2 feet apart the haulm is only about a foot high. In each case I am expecting to obtain a good crop of Sprouts of fair average quality. L. G. K.

BLANCHING CELERY WITHOUT SOIL.

To the inexperienced this may seem a strange suggestion, and so it is on the face of it; but it is a fact, nevertheless, that perhaps the best blanched Celery is produced by the aid of brown paper. Exhibitors of this vegetable now-a-days employ the old-fashioned method of blanching their sticks of Celery with the aid of soil. Certainly, no Celery could be shown in finer condition as to its blanched character than that staged by such men as Messrs. Pope and Lye, for instance. Instead of digging out such deep trenches as is generally the plan in the case of blanching with soil, sufficient only is required to enable water to be freely given to the plants to encourage a free growth. Beyond this deep trenches are a waste of time. If the plants are put out in trenches 6 inches deep that is sufficient. Another advantage gained by blanching with paper is that the plants can be fed with liquid stimulants so much longer than is the case when soil is used, because while blanching is actually going on the sticks of Celery stand clear of the trench, and in no way interfere with the application of water to the roots. Three weeks are sufficient to blanch Celery in by the aid of brown paper. The leaves ought to be loosely tied around with a piece of bast to prevent the outer ones falling down and becoming bruised. Pieces of ordinary brown paper in size according to the length and thickness of the sticks should be fastened around them sufficiently tight to prevent the light entering and thus nullify the artificial aid employed. The paper should extend quite up to the top of the sticks or joining to the leaves. Two thicknesses of paper may in some cases be needed. S. P.

Weeping trees—Graceful in outline, elegant in growth, impressive and attractive in appearance, weeping trees possess all those characteristics which render them especially valuable for the embellishment of landscape, park, and lawn. This peculiarity of form among weeping trees is a precious one, inasmuch as the contrast between the rigid upper portion of the tree and the pendulous and outar and lower parts forms a very striking and attractive feature, quite distinct from the aspects usually presented by other trees. But for all this they require to be employed discreetly, or the good effect which they are capable of producing is destroyed. They should be planted sparingly and not near one another, and carefully selected and suitable sites must be chosen for them, or half their charms will be lost; when met at every turn or too often repeated their interest and attraction are greatly diminished. They should never form large groups or masses, nor be mixed up with other trees in belts or borders. In the hands of a skilful planter they are capable of producing the most charming results, and are more effective in giving character and expression to a landscape than any other trees.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in Gardening free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper, and addressed to the Editor of GARDENING, 57, Southampton Street, Covent Garden, London. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that general answers to the same questions may often be very useful, and those who reply would do well to mention the locality in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4102.—Preserving Roseflower-leaves.—Will someone kindly tell me how to preserve Rose-leaves?—PHILIP SMITH.

4103.—Layering Carnations.—Will anyone kindly inform me how to layer Carnations, and the best time to do so?—A NOVICE.

4104.—Clipping a Bay hedge, &c.—What time of the year is the best to clip a Bay hedge? Also when to clip Box hedges?—PERRINS.

4105.—Treatment of Hakea.—Will anyone kindly inform me as to the soil required for Hakea, a native, I believe, of New Zealand?—K.

4106.—Fertus for show.—I should be much obliged if someone will kindly tell me the names of the best six new Fertus?—CONSTANT READER.

4107.—Removing ties and grafting wax.—How long are the ties and the bands to remain on the trees after the grafts begin to grow?—GRANOR.

4108.—Herbs for winter.—Will someone kindly tell me how to preserve herbs for winter use; also the best time to gather them for that purpose?—R. R. L.

4109.—Potting Cacti.—Would some kind reader tell me the best time to pot Cacti, and if they would do better outdoors now than in, as I have them in my greenhouse?—J. P. C.

4110.—Fancy cuttings, &c.—When will be the proper time for striking cuttings from Panicle, also the time for taking up Tulips to plant in a fresh place for next year?—STONOR.

4111.—Pruning flowering shrubs.—Should a Myrtle and large white Jasmine be pruned when flowering is over, as is recommended for spring flowering shrubs?—BENCOMBER.

4112.—Bignonia cupreolata.—Does this plant require much root-room? I have had one in a pot for two years, and though it grows rapidly it shows no signs of flowering.—K.

4113.—Alto-carbon light and plants.—Have any of your readers found the use of the Alto-carbon light especially beneficial to plants in a room, i.e., more so than ordinary gas?—F. P.

4114.—Destroying cockroaches.—I shall be glad if you or some of your numerous readers will inform me of the best plan to adopt to destroy and exterminate cockroaches?—CONSTANT READER.

4115.—Spiraea japonica roots.—Is it best to divide Spiraea roots when they have done flowering, and are turned out into a border, or when they are taken up in the autumn for re-planting?—ELV.

4116.—New Zealand Flax.—Can anyone inform me if New Zealand Flax flowers in this country, either in greenhouses or out-of-doors, and what treatment is required to bring it into flower?—K.

4117.—Grapes dropping off.—Is there anything that can be done to prevent Grapes dropping off a Vine, caused by the stalks breaking across about a quarter of an inch from the berry?—J. D. NEWCOMB.

4118.—Gas and plants.—Is the escape of unburnt gas in a greenhouse deleterious? Can the use of gas as an agent for heating water pipes affect plants injuriously or be taken to avoid excess?—F. P.

4119.—Destroying Chokeweed.—Will someone kindly tell me how to rid my garden of Chokeweed? Do what I can, I can't get rid of it. It comes up year after year, and chokes everything else.—A. H. N.

4120.—Flavour of Melons.—I should be glad to know why this and last year my green-fleshed Melons, of various kinds, have had a strong taste of turpentine. Is this natural to any kinds?—T. C. P.

4121.—English and foreign Tomatoes.—Will someone kindly say if foreign Tomatoes (supposing they are tested where grown) are considered superior in flavour, quality, &c., to those grown and tested in England?—G. P.

4122.—Bog-soil.—What is the nature of bog-soil? The one I am referring to is very light and black in colour. Would it be suitable for such crops as Potatoes? If not, what other vegetable crop would thrive on such land?—NOVICA.

4123.—A house border.—We are going to make a border, some 2 ft. wide, round our house, close under the windows, in which to plant creepers (scother aspect), and should be glad to know what are the latest growing, both for foliage and bloom? We want the border itself to be gay throughout the year, from spring to autumn. What would be a pretty, easily-grown selection of plants for it?—MRS. A. H. TRENDALE.

4124.—Dandelions on a lawn.—Can anyone tell me how to eradicate Dandelions from a lawn? It is impossible to get the long root up without spoiling the Grass, and the least piece left in soon sprouts again.—DARROW.

4125.—Prunus Pissardi.—I have three barries—very like Cherries but more oval—upon a Prunus Pissardi, which I bought some time ago as a foliage tree. Are such unusual in this country? And I presume they will be good to eat?—G. BAATSON.

4126.—Hard water.—Is this very objectionable for gardening purposes? If it is, how can it best be softened? Would ten drops of nitric acid to a quart do it good? This would burn the carbonate, or some of it, into a nitrate of lime.—Q.

4127.—Vines in pots.—Would anyone give me the reasons why my plants do not fruit, while they receive every necessary attention? Does the sprawling of the root about them in that way? They are seven-year-old ones.—H. W.

4128.—Pyrus japonica not flowering.—I have a very old and large bush of this, which tole year ago entirely failed to flower. Ought it to be pruned, and if so, when and how much, or would ensuring in the autumn be advisable?—T. C. A.

4129.—Ivy on a wall.—I am anxious to get Ivy to climb up a wall built of brick twelve years ago. For some reason the Ivy grows slowly, and will not cling to the wall. It has been planted several years now. What shall I do?—A. H. N.

4130.—Grafting Roses.—Will anyone kindly inform me how to graft Roses, and the best time to do so? The kinds I have are Mrs. John Laing, A. K. Williams, Madame L. Delaplace, Dur de Rohan, General Jacqueminot, and Marie Brennan.—A NOVICE.

4131.—Boronia megastigma.—I have been told that the best way for an amateur to work up a stock of Boronia megastigma is to raise it from seed? Will someone kindly tell me if this is so, and when should I sow the seed?—SOUTH STAFFORDSHIRE.

4132.—Treatment of Seakale.—Will someone please to state the present treatment for a bed of Seakale that was covered with ashes and pots in the open ground last winter? The plants are rather old, large, and untidy, and not planted in rows.—IGNORANT.

4133.—Plants for show in September.—Will someone kindly tell me what plant (not costly) I should get, and how to treat it so as to make it fit for a show to be held on a small scale on September 2nd in connection with an early morning school?—ESTUARINE.

4134.—Old mortar and garden soil.—Will "J. O. C." kindly inform me whether old mortar from a wall—rather soft and sandy—is any good to mix with old black-garden soil over the roots of Apples and Peach-trees, and the outside roots of Vines?—AMINER.

4135.—Salicaria, Petunias, and Begonias.—When is the right time to stop pinching flowers off Salicaria, and Petunias, and Begonias, for show in August, and how long will they take to be in full bloom from the time of stopping the flowers?—CONSTANT SUBSCRIBER.

4136.—Petroleum and weeds.—I have seen petroleum recommended as a destroyer of weeds on garden walks. Would someone kindly say—1. What proportion of petroleum should be used with water? and 2. What is the best way of mixing them together?—E. PRINCE.

4137.—Stands for flowers.—I intend showing Astors, Dahlias, Illythoates (Chrysanthemum Class), but having no stand I intend making some; but not knowing the various sizes I should be very pleased if some kind reader would oblige me by giving all details?—CORRATA TRINCO.

4138.—Climbing Roses.—Will someone kindly give me the names of one or two Climbing Roses (pointed to grow up the front of a house (north-west aspect)? I have at present a Gloire de Dijon, but it does not cover the wall quickly enough. Rather exposed position.—E. ATKINSON.

4139.—Treatment of the Mourning Iris.—Would someone please tell me what treatment to give to the Mourning Iris? I have got two, neither doing well. They are planted in good sandy loam in pots. In this wet weather would it be good to put them out-of-doors?—PERRINS.

4140.—Tuberous Begonias.—I have some Tuberous Begonias that were started under glass, and put out in the bed the end of May, and since then have made no growth. The soil is rich and light, and they have been kept watered. Any information or advice would thankfully be accepted by—H. HARRISON.

4141.—Heating a greenhouse.—Would "B. C. R." be kind enough to tell me if 40 feet of 4-inch pipe, heated by a 1-inch coil, & turns and 11 inches wide in the clear, is sufficient to keep a greenhouse 15 ft. by 10 ft. 8 in. up to 50 degrees in the winter? If not, would the coil carry any more pipes?—L.A.

4142.—Chrysanthemum for show.—I am growing for a show in the London Chrysanthemum Show in November next, as seedlings, and specimen plants, Mr. Bunn, Mrs. Dixon, Elaine, Vivian Morel, and Gloire Rochee. May I safely continue to until the end of July?—AMATEUR EXHIBITOR.

4143.—Tomatoes not setting.—Having this year planted both Ham Green and Hackwood Park Tomatoes, will any grower please explain why the Ham Green have failed to set any fruit, whilst all the others are growing out-of-doors of from 7 to 16? Still, all the plants seem to be in perfect condition.—PRINCE.

4144.—Plants for a south horder.—Will someone kindly give concise instructions to an amateur for keeping a narrow south horder, under a window, bright and gay from March till November, as a bed-out? The border is about 3 feet 6 inches wide, and the soil light. Locality, west of England.—AMATEUR.

4145.—Blue Hydrangeas.—Will someone kindly tell me how to make the flowers of Hydrangeas blue? I saw in some paper last year that a mixture of overcoarse mud would have the effect, but there was no alteration in the colour of the flowers. This year I have tried this mud mixed with the mould, but the only effect seems to be to give a more vigorous growth, with very dark green-coloured leaves.—J. STAFFORD.

4146.—Streptocarpus hybrids, &c.—Will someone please to inform me of the best way to get Streptocarpus hybrids to set their seed, as mine wither instead of ripening; also as to the best way of keeping the plants through the winter? Should they be grown on, or dried off like Begonias?—SOUTH STAFFORDSHIRE.

4147.—Treatment of Melons.—I wish for a few hints on Melons. Particulars: 12 plants in a ten-to-house. They are now 14 or 18 inches in height. I am after placing main shoot, and setting two or three side-shoots on to cover wires. Have I done right? Is it quite necessary to fertilise them?—TOM WILSON.

4148.—Double Violets for winter flowering.—I have a fine, healthy set of Violet plants. They will be very good by September. I shall be grateful for directions how to grow them in a Cucurbit-frame through the winter, and how should the bed be made up, &c. Also guidance as to air and water to be given?—BENCOMBER.

4149.—Roses in an unheated greenhouse.—Having a small unheated greenhouse, facing S.E. 12 ft. by 6 ft., can I satisfactorily grow Roses? Should they be grown in pots, or planted out? How many plants, and the best sorts? I will give up the house entirely to Roses, if you think I can obtain some satisfactory results?—Geo. E. EARL, London.

4150.—Mushroom-bed.—A Mushroom-bed was made up in a shady part of the garden, according to details given in GARDENING. They, however, did not start for 11 or 12 weeks. A few good dishes were gathered then, but now they come up brown and withered, with decayed stalks. What is the cause? They are sheltered with litter, and kept moist.—VERONICA.

4151.—Sorts of Apples for grafting.—I have several large Apple-trees, whose heads I intend gradually to remove, and replace with better sorts—viz., Cox's Orange Pippin, Ribston, and Blenheim Orange. Does the latter come into bearing more quickly as a graft than planted as a young tree? I had bloom on several young Ribstons planted last autumn.—GRANOR.

4152.—Legal question.—A neighbour of ours contemplates building a tree which grows in our garden close to the wall facing her house. She makes a claim for good distance, say about 16 ft. or 20 ft., from her front window. She never tells us she is going to do it down, nor, I suppose, the landlord either. Can you advise me if she has done right, or can I raise an objection?—A. R.

4153.—Tomatoes in a greenhouse.—I have a lot of Tomatoes growing in a span-roofed greenhouse. I ventilate it freely, and give the plants sufficient quantity of water every morning. The plants are in good condition, growing well and fruiting freely, but I find that the fruit is so ripens as to tend to crack. Will anyone kindly point out to me the most likely cause of this?—W. G. L.

4154.—Clematis not flowering.—Will someone kindly tell me what I can do to make Clematis bloom? It did so last year, but beds do not seem to fill so often, and lower leaves are turning yellow. It is in a small lean-to conservatory, facing south; has the sun from 11 to 5 o'clock. Should it stand in water, or only be watered frequently? Should it be kept shut in? The door is mostly open from 8 a.m. to 10 p.m.—IGNORANT.

4155.—Treatment of Raspberries.—I planted some Raspberries twelve months last autumn, and I find they are a branching kind, and very large, and will require more room. The place is covered with young Raspberries. It is the difficult to tell which to cut after fruiting. I want to fill a few gaps up with young ones. Would any kind reader tell me how to treat them? I may say they are a very large kind, and fruiting well.—OEO. SHERBORN.

4156.—Tomato-leaves injured.—Having had the damper connected with the fan of my Tomato-house accidentally pushed too far in, and left in that position all night, which caused the sulphur to escape through the joints, and destroy all the leaves on the plants, but the fruit does not seem to be affected yet. Will some reader please to state if there is any remedy that can be applied to restore them, or would it be best to pull them up? There are about 150 affected.—SHERBORN.

4157.—Treatment of Vines.—I should be grateful for advice regarding above. My gardener thinks they cannot have too much water and heat—consequently, he keeps them more or less saturated, also the footway, which he does, and he a damp heat always rising, which, he says, is necessary to make the fruit swell, and to keep off insects. For the last year or two the Grapes have had little or no bloom, and a good deal of mildew. What temperature should house be kept at?—G. J. P.

4158.—Berried Solanums.—I have several Berried Solanums that have been in a moderately cool greenhouse for over a year. They had only a few berries on them last year. About six weeks ago I cut them back, and berries are now beginning to form again. They have not been repotted. Is it too late, or should I turn them out of their pots into the open ground, and put them in fresh pots in September? The berries now on them are fair-sized ones, but not beginning to colour yet.—IGNORANT.

4159.—Flower-beds.—I should be glad of suggestions for three flower beds, on a sunny Grass plot (southern aspect), close to my house, with a view to their beauty next year. No skilled gardening or raising of plants in frames is available. Could they be kept gay throughout summer and autumn with hard herbaceous plants? I am inclined for centres of Anemone japonica or Lobelia fulgens, with bordering of Viola. I could manage a few Gladioli. Any suggestions gratefully received, with hints as to autumn preparation for same?—IGNORANT.

4160.—A dusty garden.—I have a border in front of our house, facing north, and only 10 feet from the dusty high-road, with a paling between. In spite of the long drought it looks quite gay now. The house is covered with Gloire de Dijon Roses, Clematis Hamamelis, American Bellflower, mixed Climbing Nasturtium filling up the bare space before on wire trellises. The border itself has several shrubby Veronicas, now a mass of white blossom; Garmen Stooks, coming on well, and tall spikes of Blue Canterbury Bells at the back. A variety lot of Tuffed Pansies are in full bloom, and have been all through the summer, and Blue Lobelia forms a bright edging. This border has certainly been watered constantly, though by means of a daily and nightly of all its drawbacks, has never looked so bright as it does now.—VERONICA.

4161.—**Plants for Sheffield.**—*Armeria* (*Thrift* or *Seepink*) in variety are mentioned. Should feel much obliged if "B. C. R." or anyone else would inform me the best way to get plants and where to get them, or buy seed if I have got a couple of clumps of the old pink with pink flowers, which I am gathering on the cliffs around the harbour of Plymouth, but I find they grow very rank in grass and flower in cultivation. I see a much dwarfier sort about in the gardens, with maroon seed white flowers. Any information on the above as to soil, &c., would greatly oblige? I want them to edge round some pots, with gold and silver *Yucca* in centre.—**SKARINK.**

4162.—**Tomatoes sporting.**—Some of my Tomatoes are producing abnormal blooms, apparently resulting from several flowers growing together; the fruits from the same are very irregular in shape, much grooved, and not at all desirable. Also some of the fruit trusses do not stop their growth, but grow on into stems producing leaves. What may be the cause of these two modes of sporting? The plants are in a cold-house, mainly in pots and boxes sunk in the soil, and have been fairly well watered, as well as given a pretty liberal supply of liquid-manure.—**I. P.**

4163.—**Pinks and mics.**—Will anyone inform me whether they have ever suffered any damage to *Pinks* from mice? My experience to-day seems to me to be rather a novel one, for whilst engaged in edging some very fine *Double Pinks*, a mouse appeared on the scene, and running round and round one of the plants as if to select the finest bloom, which he certainly did, stood up as high as he could, & sagged its dew, and very extensively tipped off the blossoms, and decamped with it. I should be glad to know if this is an unusual occurrence?—**ERRIPI.**

4164.—**Treatment of a Passion-flower.**—I have a *Passion-flower*, which was planted against my house three years ago, aspect due south. It looks remarkably healthy, and makes one weed every year, but, as far as I can judge, not too much. It has never once had one blossom upon it, which is a great disappointment to me. Many of my neighbours have *Passion-flowers*, and they bloom abundantly. Will someone kindly tell me his opinion on the subject? It is the Blue *Passion-flower* called *Madame de la Roche*, and on the label attached to it when it came from Lee's Nursery, Eding.—**MRS. GODDARD.**

4165.—**Hardy Climbing Roses.**—Will someone kindly give me the names of eight hardy free-growing Climbing Roses, to cover a brick wall, about 4 ft. 6 in. high, facing west. I should like the list to include some of the old-fashioned Cluster Roses, so as to have a succession of bloom through the summer and autumn. The garden is sheltered, very hot in summer, facing south-west, and sloping to a large pitch of water, so that it catches the frost in winter. Roses, with the exception of the more delicate *T. mae*, the buds of which are inclined to damp off, do exceedingly well in it.—**SOUTH WALTON.**

4166.—**Destroying Bees.**—May I ask someone to tell me the best mode of destroying Bees that have taken up quarters between the eaves and plaster in the rafters of a high-pitched roof? The eaves are hung on battens. There are three swarms in the roof, and it is found that the fumes of burning sulphur, pumped into a hole down with a snail, weak hellebore, are ineffectual to do more than stupefy the bees. What is required appears to be a powerful pump or bellows, fumes of a more destructive nature, such as sulphur, and the injection of the quantity of fresh air in the roof, the Bees may be exterminated.—**COLONEL W. D. MARSH, Colinet.**

4167.—**Planting Roses.**—&c.—Having purchased some Roses, to be planted in November, I shall be much obliged for information as to planting them, principally against a wall (west aspect). Garden well sheltered, good loam. Have been advised to put bone-meal over the roots; would that be more beneficial than stable manure? If so, what quantity to each plant? Would it be placed immediately round the roots? If not, what depth of clay should interpose? A lady whom I address is similarly situated has a *Rose-tree* with good foliage, planted fully three years, but when flowers made have been formed before expanding they wither off. Shall be glad to hear of a remedy.—**D. C. Waterford.**

4168.—**Market gardening.**—I living just taken six acres of land, with a suns wall, near London for market garden purposes, I should feel greatly obliged if you would inform me some of the most profitable crops to grow? The land is stiff loam; there is a wall on the north side about 500 yards long. I thought of throwing up a border, 15 ft. wide, along this, and planting Strawberries. The wall is between 5 ft. and 6 ft. high. Would frost do any harm to this? It faces south. There is no other land, I did not want to grow such things as Cabbages, Sprouts, Cauliflowers, &c. Would *Pinks*, *Downflowers*, *Iris*, and *Wallflowers* pay? Any information would greatly oblige.—**BERRINER.**

4169.—**Lilacs.**—Will someone kindly tell me if Persian lilacs grow without certainty than the common lilacs after transplanting, and how old it should be when procured from the nursery? The soil of my garden is dry peat on the surface, with a light reddish soil under; subsoil gravel, the whole being on coarse granite, and the ground has been lately reclaimed. The garden is on high ground, exposed to the Atlantic, which makes it almost impossible to grow trees unless shelter is provided; but this does not seem to be the difficulty in this case, as they do not prosper even in the first spring after being taken from the nursery, although they are watered and sheltered. I may also say that I have found the same difficulty with *Tamarisk* and *Sea Buck-thorn*.—**A. M.**

4170.—**Treatment of Chrysanthemums.**—About the 31st of May most of my *Chrysanthemums* produced their first natural buds, grown on the large bloom system, without any stopping. They were then removed, and the three top shoots preserved, and all after-shoots removed from day to day. The usual July bud appeared on several plants towards the end of June. On removing these, side shoots again appeared, exactly as in May, so that I had on each of the three May shoots by the end of June a July bud and three side-shoots, making in all three July buds and nine side-shoots on each plant. I then removed the three July buds and the lower two of each set of three side-shoots, so that on each plant only the uppermost side-shoots grew on each of my three May shoots. Has my procedure been correct, or should I have only removed the July bud, without also removing the two side-shoots next the uppermost side-shoot?—**U.S.**

4171.—**Double Begonias.**—I have about a dozen *Begonias* (*Double*). They are looking fairly well, but a few more or less drop their buds. They have every attention in the greenhouse, facing south-west, shaded from the sun. The ventilation is good, without draught, and not over-watered. I have cut different parts of the house, but with no better result. I am very anxious to grow *Begonias*. If you can suggest a reason I should feel so very much obliged to you. A reply in your next issue will be very acceptable. I might say I did not raise the plants, but bought them from two different growers. Curious enough my singles do better. They are potted in loam, leaf-mould, and sand; the latter two predominance.—**T. S.**

4172.—**Asparagus plumosus.**—I have some plants of *Asparagus plumosus*, which flourished well all last year, and threw up long shoots as usual. I kept them in a cool greenhouse, which seemed to suit them. After Christmas all the growth they made was a very yellow-green, as if put them into 80 degs. of heat for some weeks, so as if they would make fresh strong growth, but the frosts are still plentiful, and for several months now have not thrown up any long shoots—in fact, made very little growth, and that bushy. They have been repotted. I should be obliged if any readers of *GARDENING* could tell me the reason of their changing colour, and what treatment I ought to adopt to make them send up the usual long shoots?—**EARL RING.**

4173.—**Uses of a frame.**—During the short months of the year I have three frames laid by; could I not make use of them? One is built of brick to a south wall; the bottom is clay; the size of it is 10 feet by 7 feet; the depth at the back is 4 feet, and 2 feet in front. The other two are smaller, and built of wood, movable, 5 feet by 5 feet. Will any reader of *GARDENING* kindly advise me what to grow? Could I grow *Saxifraga* in the large one? I have a small weed by full of them; if so, what depth of soil should I use? And what other bulb could I grow with them? How much earlier could I get them? Should want them to remain as long as they would flower satisfactorily, as I want the lights the latter part of March for another frame. We do not use this one in summer, as it is so inconvenient to get to the Van. Can you suggest any grow in the other two? Have kept *Calceolarias* and *Rohrerias* in the large one. Could I not keep them during the winter in a *Celery trench*?—**I. N.**

4174.—**Fruit-trees.**—&c.—Perhaps "J. C. G." or "E. H." will oblige with advice. I would find their opinions are very valuable. I have a south wall, about 100 feet run, 8 feet high. Nine years ago I planted four *Peach* trees, four *Nectarines*, and two *Apricots*. They are, of course, all large trees, and have quite covered the wall; but the worst part of the matter is they have never had a crop. They bloom well, but being a south wall they get early and the frost takes all the bloom, or nearly all. The most fruit I ever had is about six dozen from all the trees. Now my *Black Hamburgh Vines*, these have now made good progress, the young rods this season being 14 ft. long and nearly 1 in. thick at base. I believe management has been correct all through, sir being put on gradually as soon as heat rises above 65 degs., and clearing and damping down thoroughly at 4 to 4.30. Now, my trouble is this, and I should be much obliged if someone would explain the cause: The young foliage, for about 3 feet from top upwards, is partly brown and withered, some young leaves crumbling to dust in the hand when dry. The older leaves are low down, the rods are quite healthy, save one or two are partly scorched. The wires are only 9 in. from the glass, and my opinion is that this is the cause. Should I increase the distance by 18 in. or 20 in.? I may add that the border is outside, and is well drained, but not too dry, as it has been well watered two or three times, and is mulched with long manure. The house is well ventilated, but avoiding draughts, and everything in quite a free from above, with the above exception. I should be glad to give further details if required, as I am anxious to know what causes the mischief, so that I can avoid it next year.—**HUDDERSTON.**

4175.—**A loan to vinery.**—My vinery is a lean-to, facing S.W., roof pitch 45 degs. Was planted 13 months ago with young *Black Hamburgh Vines*. These have now made good progress, the young rods this season being 14 ft. long and nearly 1 in. thick at base. I believe management has been correct all through, sir being put on gradually as soon as heat rises above 65 degs., and clearing and damping down thoroughly at 4 to 4.30. Now, my trouble is this, and I should be much obliged if someone would explain the cause: The young foliage, for about 3 feet from top upwards, is partly brown and withered, some young leaves crumbling to dust in the hand when dry. The older leaves are low down, the rods are quite healthy, save one or two are partly scorched. The wires are only 9 in. from the glass, and my opinion is that this is the cause. Should I increase the distance by 18 in. or 20 in.? I may add that the border is outside, and is well drained, but not too dry, as it has been well watered two or three times, and is mulched with long manure. The house is well ventilated, but avoiding draughts, and everything in quite a free from above, with the above exception. I should be glad to give further details if required, as I am anxious to know what causes the mischief, so that I can avoid it next year.—**HUDDERSTON.**

4176.—**Agaves (J. B.).**—I do not think it is of any use to quote you names of these plants, for I do not think any of our nurserymen now devote their space to them, and if names were given yet would not be able to get them. I am very sorry to have to acknowledge that the taste for these plants has apparently died out entirely, for, as we say, they are beautiful plants, but, I suppose, are too slow for this fast age.—**J. J.**

4177.—**Odontoglossum Alexandræ.**—*May Scott* says she has this plant in flower for the first time, and sends one, asking if it is a good variety? Yes, it is a very good ordinary form; there is nothing to brag about in it, but you are fortunate in getting such a nice flower of the pure white, normal type of *Alexandræ*. I am much obliged for all the good you have to say, and am glad you have found my hints of some assistance.—**M. R.**

4178.—**Utricularia montana** (*James O'Connor*).—The flower very small is not so Orchid, but a member of the *Heather-wort* family. This species is a native of New Zealand, and it is used with the Orchid and is in fact a member of the same order, but, notwithstanding, it does not belong to the same order, and I certainly should not say you or anyone else was I judge, and should be regarded as one of a certain member of *Orchid*.—**M. B.**

4179.—**Limnorchis Humboldtii.**—*J. Cullum* sends me a flower of this beautiful, yellow-flowered aquatic, this is a plant which grows very rapidly in loam; and placed in shallow water in the stove aquarium. The leaves are rounded. They float upon the water, and are light green. The yellow flowers stand erect, and are produced all through the summer; but to keep it through the winter is more difficult. I have found it kept best taken out of the water, and stood upon the stage in the stove, keeping it well supplied with moisture.—**J. J.**

4180.—**Petras volubilis** (*G. Hamer*).—I am glad once again to see this plant, which I used to grow some years ago. The flowers you sent were nearly all out of their colour; these latter a deep blue-purple, whilst the flowers themselves are light-blue. I am glad you did not send a leaf, because these are so dry and rough that I cannot bear to touch them, and the barest grazing would make them render the plants less cared for than it otherwise would be. The plant grown well in loam, and requires plenty of root-room, and the pots should be well drained.—**J. J.**

4181.—**Orchids for open border** (*H. W.*).—My *Dorcas* correspondent appears determined to grow some of these plants, if it can be possible, and I hope he will succeed; and in order that he may not fail I would again counsel him to plant them in the border, in the same soil from which they were taken. You may grow all the British kinds, if properly planted (when, if these are taken up at the proper time, all will be well), including the *Lady's Slipper* (*Cypripedium calceolus*), but this, as it is nearly or quite extinct as a native plant, you must either purchase or collect in the north of Europe. There are also several North American species of this genus which would succeed, but I advise you to take a run to York, and look round Messrs. Backhouse's nursery, where you will find many that would please you.—**M. E.**

4182.—**Palms for the greenhouse** (*G. W. Swanderland*).—I am asked if I can recommend about a dozen kinds which will thrive in such a structure. The house never gets frost in during the coldest winter, and he asks where he may get seeds of the kinds which I should recommend? Well, the latter question may remain unanswered, for seeds of these plants would not be of much service to you, but you may get good-sized plants, so that they would have an effect at once; then get a few seeds and sow them, when you will see how you would have been served by depending upon these plants. To make an effect, the following kinds will be found to answer your purpose: *Chamaerops rotundifolia*, *C. excelsa*, *C. Fortunei*, *Livistona australis*, *L. borbonica*, *Phoenix australis*, *R. Belmoreana*, *R. Fosteriana*, *Phoenix australis*, *P. Florida*, *Sequoia gigantea*. Good examples of all these plants can be had at a reasonable cost, and they will make you a grand display. To make a little variation, and to set these plants off, some few *New Zealand Ti-trees* (*Dracena australis*) should be used.—**J. JARVIS.**

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of *GARDENING ILLUSTRATED*, 37, Southampton-street, Strand, London, W. C.

Names of plants.—*H. N.*—1, Not recognized; 2, *Dogwood* (*Cornus Mas*).—*Robt. Gibb.*—We are sorry we cannot name the *Lilium* sent, but they were crushed out of recognition in the post.—*G. Freine.*—Please send better specimens.—*E. Gibbes.*—Impossible to us from such specimens.—*Mrs. Bryant.*—*Diplois glaucus*—*Braconia*.—*Yves.*—*Catananche coraculæ*.—*H. W. Led.*—1, Probably *Catananche coraculæ*; 2, *Sedum Ewersi*; 3, *Sedum Sibthorpi*, probably.—*H. J. Shepherd.*—*Eucyamus argenteus*.—*N. F. Denny.*—A shrubby *Spiræa*.—*Mrs Tweeddale.*—*Elmagnus variegata*.—*J. E. M.*—All *Campanula*, apparently, but too stale to name.—*W. O.*—Impossible to name from such scraps. It has been pointed out over and over again in *GARDENING* that good fresh specimens must be sent.—*Yalding.*—*Oranula coccolæ*.—*J. McDonell.*—*Phlemis frutescens*.—*Mildred.*—Not recognized.—*W. T. G.*—1, *Hydrangea*; 2, *Hydrangea*; 3, *Hydrangea*; 4, *Hydrangea*; 5, *Hydrangea*; 6, *Hydrangea*; 7, *Hydrangea*; 8, *Hydrangea*; 9, *Hydrangea*; 10, *Hydrangea*; 11, *Hydrangea*; 12, *Hydrangea*; 13, *Hydrangea*; injure the Vines. — *Le Mouzon, Edinburgh.* — Apply to Mr. A. G. Buller, The Lilies, 124, Beckenham-road, Beckenham, Kent. — *Amor.* — Mr. Barton's letter has been received, but it contained no credit last. — *Francis A. Shepherd.* — This Clematis often withers like this, especially in a dry season, but there is no really assignable cause. — *Chelmsford.* — The Daisy-fly (*Phytomyia affinis*) is many times mentioned in *GARDENING*. — *J. S.* — The Grapes are "scalded" for want of early ventilation. — *A Subscriber, S. Dorset.* — The Peach trees are badly attacked with green-fly, and should have been syringed with Tobacco-water or dusted over with Tobacco-powder early in the season. — *Signatures.* — Box received with a Rose-shoot inside, but we could see no grub or grubs. — *A. B. S.* — We should say the Tomatoes are allowed to become dry at the root, and so the fruit does not grow. — *Amicus.* — Yes; there is a pink, shrubby Spiraea. — *S. P. C.* — The box was crushed up quite flat, and, of course, the insects could not be recognized. — *A. Greenman, Greywell, Hants.* — The Melons are attacked by red-spider, through too dry an atmosphere. Water the roots and sponge the leaves. — *C. V. P.* — Apply to Messrs. Barr & Sons, Kings-street, Covent-garden, London, W.C. — *W. Kemp.* — Read *GARDENING ILLUSTRATED* regularly, and send in any queries you like. — *E. Foster.* — Certainly; send as many photographs as you like for the competition. — *Antoinette.* — The shoots sent are Brier suckers, and should be removed. — *J. W. Clark.* — We have the photograph, and it will be included in our competition, and returned if successful. — *C. B. Cross.* — The Ferns have scales on them. Some Ferns may be watered overhead, but generally not so. We cannot name broad-leaved Ferns. Send again. — *Cheshire.* — Apply to Mr. J. Cheal, Nurseryman, Crawley, Sussex. — *Z.* — The Tomatoes have the Potato disease — *Carbon.* — Yes; there is a Green Rose in cultivation, but we do not think it is of much value. — *James Moore.* — Most probably the Bees are suffering from the long continued drought. We cannot see any other cause.

BEES.

SEASONABLE NOTES.

DIFFICULTY is sometimes experienced in getting the Bees to commence work in sections when placed on the top of the hive, particularly in the event of the hive not being strong in Bees. If, however, sections are first put into brood frames and these introduced into the hive on either side of the cluster of Bees, they are, as a rule, taken to, and work carried on in them very readily. As soon as the foundation is worked out the sections can be removed with the adhering Bees and placed in the crate on the top of the hive. Other Bees will thereby be induced to go up, and the work in the sections will go on. Work in sections is always more readily commenced in the body of the hive than on the top. The Bees can sometimes be forced up into the sections by ramming some of the frames from the hive and contracting the brood-nest by means of the division-boards. Being cramped for room, the Bees go up into the sections, and there store all surplus honey.

STRIPPIING SECTIONS — Three stories of sections can be used at one time in the strip-ping system. On the commencement of the honey flow a crate of sectional boxes, provided with thin foundation, is placed over the frames of the hive. When the sections have been worked in, and are about two-thirds full, the crate is raised, and one containing empty sections placed beneath it. These are also in turn raised, and a third placed below on the top of the hive. When there is a good honey harvest the top crate is soon completed, when it is removed. This is continued so long as the honey harvest lasts, but as soon as the honey flow begins to decline no more sections are given, but the Bees are encouraged to finish those on hand. Sections of comb-honey should always be removed from the hive as soon as finished in order to preserve the whiteness of the comb. By inverting sections when nearly completed, and when the honey flow is abundant, enables the Bees to finish them off better, and the number of holes at the corners are thereby reduced.

HONEY FOR MARKET. — Care should be taken that all samples of honey present as neat and attractive appearance as possible. Sections of comb-honey should be quite filled, all the cells being sealed and the surfaces of combs quite even. Evenness of surface is attained by the use of dividers between the section-boxes, which allow but a quarter of an inch at the top and bottom for the passage of the Bees, thus all projections or bulgings are obviated. Sections should be removed before the cappings of the cells are thickened by the Bees. Thinness of capping being considered one of the chief points of perfection in super-honey. Whiteness of comb is another important feature, and a further reason why sections should be removed from the hive as soon as completed, for, after completion the heat of the hive and the

traffic of the Bees mar the spotless whiteness of the newly-made comb. The honey within the comb, when held to the light, should present an amber colour, brightness, and transparency. Care should be taken to prevent granulation of honey after removal from the hive. This may be effected by keeping it in a somewhat warm temperature. All sections in each crate should matob in style of work, quality, and colour. Sections should be glazed on either side; but if they are marketed in glazed crates the glazing of the sections is not necessary. Travelling-crates are very nice things in which to send sections to market. They are glazed on two sides, so that the contents are visible, and present a very attractive appearance when filled with well-finished sections. The demand for honey is increasing, and that which presents the neatest appearance finds the readiest sale. Extracted or run-honey should be put up in clear glass jars holding just one pound. It is important that the glass be clear, otherwise the appearance of the honey is spoiled. Each jar should have an attractive label, and be tied down with vegetable parchment, which, if moistened with the white of an egg before being tied over the honey-jar, an almost perfect seal-tight will be found, permitting to be sent on a journey without danger of leakage. Or the jars may be corked, and the corks covered with metal capsules. Screw-cap bottles are now much in vogue. If the small corks used with these are dipped in melted wax, and the top screwed down upon them, there will be no leakage. For exhibiting at shows sections are often placed in coloured cardboard boxes, having glass fitted so that both sides of the comb can be examined. Fancy tin cases, coloured different tints, are also used. S. S. G., Parkston.

4026.—Unhealthy fowl — I cannot enlighten "E. M. B." as to the name of the ailment from which her fowl suffers, but I have frequently met with the disorder, and generally the victim has either been bred from unhealthy stock, or has been reared under unfavourable conditions. For example, chickens hatched late in autumn, and indifferently treated during the cold weather, will often show symptoms of the ailment in spring, and I have occasionally met with chicks bred from sounder stock which have gone wrong. The quietist might prick the air vessels and liberate the air, but they will probably reappear. The wisest course is to fatten the fowl and kill it when good enough. — *Dorling.*

GARDEN AND PLANT PHOTODGRAPHS.

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded.

The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; cut flowers, prettily arranged; pretty cottage gardens; our best fruits on the branch or branches, not in dishes; standard vegetables; good flower-gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS. — A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS. — First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS. — A prize of FIVE GUINEAS for the sander of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS. — A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or bush fruits, to be shown on the branches, not in dishes. No prize will be awarded to photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES. — A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in July, 1895.

WHAT TO AVOID. — Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dewy flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 6 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overcrowded. The following are the rules to be observed by all competitors: —

FIRST. — The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND. — The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD. — All communications relating to the competition must be addressed to the Editor of *GARDENING ILLUSTRATED*, 37, Southampton-street, Covent-garden, London, W.C., and marked "Photographic Competition." All competitors wishing their photographs returned, or not to be used for any other purpose, should stamp of sufficient value for that purpose.

What!! Corns?

Yes.

Then use

NOTES ON ANNUAL FLOWERS.

The annual flowers this year are very poor, and those that were transplanted have practically failed. But if this class is not in condition this season, when exceptionally hot weather from quite early spring has prevailed, they must not be condemned. Annuals are useful for amateurs, especially those with small purses, who wish for gay gardens, but cannot afford much in buying established plants. A few packets of good seed, properly sown and the seedlings well cared for, will give a variety of colours. Such annuals as Viscaria, Poppy, Larkspur, Silene, Nemophila, and Sweet Pea may be sown in the autumn, as they are as thoroughly hardy; but in the majority of instances, however, seed sowing must be deferred until spring, although under natural conditions the seed is scattered on the ground in autumn. Our winters are too treacherous to behave always kindly to the many beautiful annuals from California and other countries that add to the beauty of English gardens, and in some instances it is necessary, as in the case of the China Asters, to sow the seed under glass. The culture of the annual is very simple. When the seed is to be raised it must be sown in shallow pots or pans, usually the latter, and very thiohy. Use good soil and water carefully, as the seed is very fine and delicate, and may be washed away. When the seedlings appear and are of sufficient size to handle, prick them off into other pans filled with the same kind of soil, and in due time, after well hardening them off, pising them in the positions they are to fill in the garden. China Asters, Stocks, the showy Chinese Pinks, Gaillardias, Godetias, Heliochrysum, or Everlastings, Lobelias, Nicotiana glauca (Sweet-scented Tobacco), Petunias, PENTSTEMON, annual Chrysanthemums, Salpiglossis, Scabranthus, African Marigolds, and the quaint Zinnias are all beautiful. Some of these, as the Petunia, are not strictly annuals, but may be called such, as the seed is sown the same year as the plant flowers, and another batch sown again the following year, one year sufficing for culture and the display of blossom. In dealing with annuals sown under glass always take care that the seedlings, before being transferred to the open ground, are thoroughly hardened. There must be no doubt about this, otherwise they will assuredly come to grief when pnt out to face the trials of English weather. As regards the outdoor culture of annuals, two things must in particular be taken account of—their sowing and careful after-attention. The soil, in the first place, must be prepared well, and this was not the case a few years ago when annuals were regarded as short-lived, weedy, and so forth. This character was gained, not through deficiencies in the annuals themselves, but simply indifferent cultivation. A dozen seedlings were permitted to struggle for life on a space not large enough for half that number. It was truly a case of the "survival of the fittest," but, unfortunately, the "fittest," after the battle, received such a shock that their way through life was sadly impeded. Not wlely and well prepare the soil by making it moderately light, and having a due surface, as

the seeds are very small. Sow thinly, and when the seedlings appear above ground thin them out well, so that each may have sufficient space to develop its proper character. The usual way is to sow in lines, but small clumps on the border are very showy, whilst a bed of annuals is a departure from the usual run of plants found in gardens. Aim at scouring effect by bald masses, as it is only in this way that fine colouring is gained. Sometimes there is an old-fashioned border, in which the White Lily sends up its spikes of white flowers, and the Cabbage Rose makes beautiful in the summer months, but yet there is an absence of variety. It is under these conditions that annuals may be made of use, and if they send their little flower-laden shoots on to the walk, it will break up the usually formal edge. The writer remembers a very charming border filled with bulbous plants, and when these were over, a succession was maintained by a good selection of annuals, which do not root deeply, therefore were not hurtful to the permanent occupants. The broad masses of annuals spreading about in artless fashion over the border, and running on to the walk, were homely, and a decidedly interesting picture, very different from the septennials usually present in gardens. Annuals are amateurs' flowers of a useful and interesting type. It is not difficult to sow the seed, and with ordinary attention a good reward will be reaped. It is not wise to have too many kinds, and the following are recommended for gardens of ordinary size, or choice may be made from this small list:

BARTONIA AUREA (golden-yellow), the seed may be sown in autumn for early flowering; BRACHYOOME, popularly known as the Swan River Daisy, very dweri, and with flowers like those of a Cineraria; Calendula, or Cape Marigold, Calliopsis, the old-fashioned Candytuft, Cornflowers in various colours, rose, purple, white, and blue; Chrysanthemums, the beautiful Clarkias, Collinsias, Convolvulus, Chinese or Indian Pinks (very showy annuals, best raised under glass, and represented by several varieties), Eschscholtzie, or Extingisher-flower, Gillias, Godetia Duchess of Albany, of the purest white; Sunflowers, Heliochrysum, better known as Everlastings; Larkspurs, Lavatera trimestris, a lovely rose-coloured annual, and its variety alba; Linarias, Lupines, Malopes, the quaint Marvel of Peru, Night-scented Stock, Marigolds, Mignonette, Nasturtium of various colours, the Blue Nemophila, Love-in-a-Mist (botanically called Nigella), Sweet Peas, Poppies of many kinds, Salpiglossis, Saponarias, Silene or Catchfly, Sweet Sultan, Virginian Stock, and Viscarias. One of the most beautiful is the Sweet Pea, and during recent years this homely flower has been much improved. Sweet Peas may be used to screen unsightly objects, and also sown in clumps in the mixed border, the shoots being trained to twiggy sticks. To gain a succession of bloom sow in the autumn, these flowering early, and also sow in the spring to carry on the time of Sweet Pea until the verge of winter. Such kinds as Adonis (rose-pink), Apple Blossom (white and rose), Beatrice (earmine), Mrs. Gladstone (pink), and Cardinal (scarlet) are very telling, but the old kinds that our grandmothers were wont to

form into little posies for the old-fashioned parlour are beautiful still in spite of a small army of novelties. A distinct gain to our gardens is the Night-scented Tobacco (Nicotiana glauca), and plants put out in May from seed sown under glass early in the year will bloom freely in the summer. The flowers are produced with great freedom, and are creamy-white in colour, smelling sweetly in the evening time, a few plants scenting the garden. Some of the seedlings may be reserved for growing on in pots, to adorn the conservatory or greenhouse. The Poppies—at least, the annual—kinds are not made sufficient use of in small gardens. They are of little value for cutting, lasting but a brief time, and their odour is scarcely pleasant, but in the garden the flowers tell effectively. The beautiful French kinds, Peony-flowered, and field varieties, are full of grace and charm. The latter are selected from the common P. Rhæas, the plague of the cornfield, the varieties having flowers of exquisite expression, the colours are so soft and well blended. V. C.

4118.—Gas and plants.—Unburnt gas is certainly injurious to plant life, besides being highly dangerous, as when mixed with air beyond a certain point it will explode like gunpowder if a light happens to come in contact with it. The fumes, or products of the combustion of gas, are even more deadly to plant life, and if even a small quantity is allowed to escape into a greenhouse no end of damage will quickly result. With a properly-arranged flue to carry off the fumes outside, a small structure may be safely and satisfactorily heated by means of gas; but, in any case, it is better to have the boiler or stove situated outside rather than in.—B. C. R.

—An escape of gas into a greenhouse is certainly injurious to the plants, but gas may be used with perfect safety as a heating power in a properly constructed boiler.—E. H.

4108.—Market gardening.—Strawberries ought to do remarkably well on the proposed border, and would come in early. Let the border slope 3 feet or 4 feet from back to front. Part of it might be devoted to early Lettuces and Cauliflowers, if desired. The wall is just the place for fruit-trees, and should be planted with Peaches, Apricots, choice Pears, and a few Plums. It is a difficult matter to advise anyone what to grow for profit in these days, everything is so overdone, and the returns depend so greatly on the season, as well as on the demand. Hundreds of acres of Strawberries are being ploughed up this year. Flowers are almost a drag in the London markets now, and, unless you can get them in early, or hit some popular fancy, very unprofitable at present. I think if I had such a place I should put up a range of roomy (mostly) unheated houses, and grow early Lettuces, salads, Cauliflowers, &c., during the winter and spring, following on with Strawberries to ripen in May, and then Tomatoes, &c., afterwards.—B. C. R.

4114.—Destroying cockroaches.—There is nothing to come near the Demon beetle-trap for clearing off these vermin. Set with a piece of soft cheese, and you will catch them as fast by hand as a light, and later on by side-traps; at last you will think yourself lucky if you can count ten, either old or young.—A. G. BROWN.

GARDEN WORK.*

Conservatory.

Climbing plants which creep up to the roof will require a good deal of water at the root, including stimulants occasionally. All things, both in pots and planted in borders, dry very fast in such weather as the last month has been. Among the climbers which are now in flower are Fuchsia-flowers, Taccaea, Jasmines, and Mandevilla suaveolens. The last-named is a very sweet-flower, nice for outlying—a splendid plant for a cool-house. What the ventilators can be kept open night and day this system of roof ventilation will sell all greenhouse plants now. There is a good deal of usefulness in the Abutilon family. They may be had in all colours, and will flower very freely all the year round. When the principal display is required in winter it will be better to prune back rather hard now, and get a new growth on by the autumn. The rest will lead to the production of more and better flowers through the winter. Cuttings will root now in a shady part of the greenhouse, or in a cold frame, shaded and kept close. Colours to put on colour must not be shaded. They want the lightest position available, but the atmosphere must be genial, not dry and parching, or the foliage will suffer. If Roses in pots require repotting they should have attention. Good loam forms the basis of most potting composts for all plants, except Heaths, Aralia, Epiphytes, and a few of the most delicate-rooted of the Australian and Cape plants. Firm potting and good drainage are essential; never repot a plant when the ball of roots is dry. This invariably leads to trouble. If enough water is given to moisten the dry ball the new soil is soured, and the plant does not succeed. Better give the plant a good soil, and delay repotting for a couple of hours, so that the surplus water may drain away. The early-flowering Pelargoniums will now have broken into growth, and as soon as the young shoots are an inch or so long shake out and reduce lung, straggling roots, and repot in clean pots of the same size. Turfy loam, with a little old manure and some sharp sand, will suit them admirably. Press the soil in the pots firmly. Sow Mignonette for winter-blooming in good sowed loam, with a little old cow-mare rammed firmly in the pots, which will do very well. A very useful and cheap variety is the 'Lily', and this out the weekly plants when they come up. Mochaet is a good variety. Syringe hard-wooded plants outside every evening.

Stove.

Ornamental Begonias of the Rex type are in good leaves now, and are very interesting when mixed with Ferns, Maiden-hair, and others. Cuttings will root now if more stock is required; they will do very well in a cool-house for a time now; must not be syringed much, or exposed to draught, or the delicate leaves will suffer. Among Caladiums argyreata is a beautiful little plant for the table in a fancy vase. The usual winter-flowering stuff will be coming on fast now. Poinsettias or Euphorbias must not be stopped, but Begonias, Jussieuas, and other soft-wooded things may have the long shoots stopped with advantage. Provision should be made for a good stock of plants for table and room decoration. Many of these must be grown in comparatively small pots. Large Palms and things of like character will be required for backgrounds; but in moderate-sized places table plants both for dining-room and drawing-room should be confined to 6-inch or 8-inch pots, and very pretty stuff may be had in these sized pots. Well-grown little plants are suitable with advantage. Balsams are little plants, and will last in good condition well into the winter in a warm-house. It is useful for the exhibitor to make up specimens by planting several in the same pot, but for home decoration when they are required to be done often in a hurry there is some advantage in placing two or three plants in each pot. Say, for instance, we want to make up a specimen Begonia or even a specimen Poinsettia, then this plant does not lead itself very well to the making up plan, then it can be done by placing three or more plants in a pot.

Unheated Greenhouse.

Veronica, such as Andersons, Glorie de Lorraine, Blue Gem, and others, are capital plants for the cool-house in autumn and winter. They may be grown outside till autumn. See the notes on ferns from mildew and insects. Syringe with a solution of sulphur soap; this appears to be coming into use as a wash for plants infested with insects or any other ailment.

Ferns under Glass.

The potting may be done now. Seedlings from boxes or frames may be potted off. Cases may be filled with fresh Ferns, or new soil may be added to old Ferns without taking the plants out of the case. Ferns, or, as called, planted with Ferns and foliage plants, when tastefully filled, are very interesting in the rooms, and they will help to furnish the dark places where flowering plants will not last any time. Do not syringe Maiden-hair, but damp floors and syringe among the pots on the stages to create a moist atmosphere.

Chrysanthemum Notes.

Earwigs are a terrible pest this year. They are literally swarming among our plants, especially the delicate growers. A serious effort must be made to reduce their number by hand-picking, especially at night, when they are feeding. Go round with a lantern about nine or ten o'clock, and destroy them as seen. Flies they must be more promptly, with an insecticide of some kind. Quassia-chips or Tobacco-powder, mixed with soft-soap, will be suitable. They must be securely staked, and there must be no crowding. Disbudbing will be necessary to obtain fine blooms, and the watering must have careful attention. They must be looked over in the morning, and again in the afternoon, or whenever they require it.

Cold Frames.

Ons are all filled with young stuff, and would be if we had more. Frames are better than houses for summer work for bringing on young plants. Cucumbers and Melons in frames will during this scorching weather require a good deal of water. Give a little air early in the morning, and keep the growth thin.

* In cold or northern districts the operations referred to under "Garden Work" may be done a few days or a fortnight later than the more indicative of the capability of results.

Window Gardening.

Give liquid-manure to window-boxes, also to Fuchsias, and other large plants, such as Ageratum, Brugmansia, and Myrtles standing in tubs or large pots in courtyards or elsewhere. Tuberous Begonias growing in rather small pots will also be helped by liquid-manure. I do not know why, but Tuberous Begonias are not much seen in town houses. I expect gas is the great enemy to this class of plants whose flowers soon drop if exposed to gas fumes. But the old variety Begonia Weltonensis succeeds well as a town plant. The Tuberous Begonia cannot be hawked about by the travelling florist; it will not bear the rough usage of the hawk's basket. Plumbago capensis and cespensis sibs are prettily in bloom now.

Outdoor Garden.

Cuttings of Roses just getting a bit firm will root now under glass, if kept close and shaded. But in all cases of propagating under glass it is an advantage to open the lights for half an hour in the morning, before the sun gets hot, to let out the damp accumulations of the night. The lights will, of course, be closed before the fallings of the cuttings shows any signs of distress. Place the cuttings in pots, and plunge in Cocoa-fibre or old leaves. Get on with the budding. No one ever has too many Roses, and the Roses propagated at home are the most lasting. Coccinula the layering of Carnations, Plectenes, and Pinks if more stock is required. The reason why Carnations are not a success in many soils is the neglect of one important proposition. Of course, regular Carnation growers layer the plants every year, but hundreds of people who buy Carnations never think of layering the young shoots, or if they do layer them the work is driven off so late the layers have not time to get well rooted, and so they do not give satisfaction. The weather has been too dry to prick root seedlings, but should a damped period arrive Wallflowers, Caerthyry Bells, and other hardy things sown in April and May should be pricked off the streets. Potatoes may be propagated from cuttings as soon as the young shoots start a way from the top centres of the plants. Cuttings of the flowering aboch will not in a season like the present be success. I do not think I shall be in a hurry with the Fancy cuttings this year. Wait for the young abochs.

Fruit Garden.

No one need be afraid to begin the summer pruning of wall and other trained trees now. Shorten back the brasswood to three or four leaves, but leave all leaders unshortened, and tie or nail them in the case of wall-trees and espaliers. The wood of bush trees and pyramids should be thinned suitably to let in the air and sunshine. In some gardens the bush or pyramid is taking the place of the espalier. This, I think, to be regretted as the fruit culture is not so interesting, and the quality of the fruit cannot be so good. The only objection to espaliers are they are rather slow in coming into bearing. Lines of espaliers by the side of walls always give a nice finish to the garden. Next to espaliers, as regards Apple culture, bush-trees, or the paradise are to be commended for small gardens. The trees bear so early, and the fruits are always of fine quality. Whenever waste to grow Apples for winter use, plant these fruit-trees on the cold-leaved Paradise. Give the finishing touches to the land intended for Strawberries. This may in the case of land not in good heart take the form of a top-dressing of short manure forked in. A dressing of soil is always beneficial. Morello Cherries and Red Currants, and other fruits which are to be kept any time, must be netted up to save them from birds. Wasps are likely to be troublesome this season; find and seal their entrances on the wall intended for Strawberries. Give abundant ventilation to Grapes and Fuchsias ripening, and keep down insects. When Vines have been allowed to run a little while do not remove all surplus growth at once, the check will be too great. Spread the work over a week or two days or longer.

Vegetable Garden.

Everything is still suffering from the protracted drought, and many a dry hole has been made, and will be for some allowing things to slide. He that sows to the end shall be saved to true in all seasons, but in some cases the water supply has given out, and then the only resource beyond minding (which is exceedingly valuable) is the hoe. In very good land sufficiently nourished with manure the hoe has done better than the water-pot. A loose surface where the roots have a well-stocked layer below is better than watering. Sow Wallflowers and Poppy-blossoms. It is time all Onions and Leeks were out now. Lettuce and Celery will not attain the same size as the plants which have a longer time to grow, but the under-size heads are the best kippers. Fill up vacant land with Coleworts or greens of some kind. Sow Brown Cos Lettuces and green curled Endive very freely, and plant out previous sowings. Peas have done better than might have been expected, but Cauliflowers of the early kinds have been poor. Autumn Giant just coming up will be better. Sow Cucumber seeds to fill the autumn and winter houses. There is no better kind than Lookie's Perfection; it is an improvement in every way upon Telegraph. Cucumbers in bearing will require plenty of support now, and the finger and thumb or knife must be used freely to keep growth fairly thin. This is the best season for open air Tomatoes we have had since the Jubilee year, and where the plants have been heavily mulched they are doing well.

E. HOBART.

Work in the Town Garden.

Chrysanthemum in pots will now demand a large share of attention and care. All the plants that were placed in the flowering pots about the middle of last month—the right date for the final shift in the case of plants intended for exhibition or similar purposes here in the south—are now getting nearly hold of the fresh soil, and will be growing freely by this time. More liberal supplies of water will now be required, and on hot, sunny days, such as we have had so many of late, most of the plants will need to be watered twice, if not thrice. The daily overhead shower with the syringe or garden-auger must not be omitted as long as the weather remains so dry. This not only keeps the plants fresh and growing, but greatly militates against attacks of insects. Thrips are very troublesome and will be very numerous in the plants. The insects must be separated to get rid of them by the hand. The buds begin to show, or many of the points will be

found crippled and blind. The best time to syringe is towards the close of the afternoon, when the sun begins to lose some of its power, and unless there is a good dew in the night another dash about 8 or 9 p.m. will do a lot of good on the approach of dawn. Do not begin "feeding" the plants too soon. As long as they continue to make healthy progress they are better without it—at least, for the present; but as it is of the utmost importance to get them to be in full and vigorous growth while the buds are being formed (this commencing early in August) they should now be very carefully watched, and any that show the least signs of carelessness must receive a little assistance in time. Of course, plants that were put out for the last time in May, according to the practice of some, must have a little stimulant of some kind before the others. Persevere in layering Carnations, placing some nice fresh sandy soil round each plant to peg the layers down into, covering them rather deeper than usual, and keeping all moderately and regularly moist. Carnations in pots now in bloom under glass should be very lightly shaded to preserve the flowers as beautiful as long as possible, but give them plenty of air both by night and day. When grown in pots these plants must not be overwatered, or they are liable to become gummy and go off. If they get very dry, it is best to give them only a little water, syringing the plants, the pots, and all surrounding surfaces well and repeatedly, until they come round again. Scarborough Lilies may be placed out-of-doors under a sunny wall for a month to ripen the growth, and induce the formation of flowers. B. C. H.

THE OOMING WEEK'S WORK.

Extracts from a garden diary from July 22nd to July 29th.

Made a last sowing of Ellman's Early Cabbage, also sowed Brown Cos Lettuce and Grand Curled Rediva. These will come in useful for lifting into frames for winter use. Prickly Spinach and Tripoli Onions will also be sown during the present week. Although probably both Onions and Spinach will be sown again early in August those who can make two or three sowings of anything stand a better chance of securing a good successional supply than when one sowing only is made. If the weather is very dry the plants will come in useful. Just previous to sowing, sowed Cucumber seeds to raise plants for filling a house for winter. Put in a lot of cuttings of Tomatoes Ham Green Favourite for growing in large pots for winter. I have tried a good sort for this work, and the conclusion I have arrived at is that Ham Green is the best. Critorian and Conference set freely, but the fruits are not large enough. Planted a pit with No Fies Ultra French Beans. These will come in useful. Just previous to sowing, simply the protection of glass will suffice, with a covering of mats on frosty nights in late autumn. After this, if a succession of Beans are required they will be planted in pots and brought on in heated structures as required. Earthed up early Celery. Paper covers do very well for the earliest lot, but I always think the flavour is better when the plants are earthed to finish the blanching. The paper does very well to start with, and does not interfere with the watering. For exhibiting only clear, well blanching growth is required, favour or even crispness is not of much consequence. All Peas and Beans are gathered as soon as large enough for use; if left to get old bearing ceases at once, while if the pods are gathered regularly as soon as large enough for use fresh blossoms are formed in succession, and the same plants will run themselves out in bearing a considerable period. Instead of sowing seeds, I planted a bed of Sutton's Sulham Fries Celery. The plants were sown outside, and though the heads will not be large they will keep well and come in useful in the spring. The seed pods are being regularly ploughed in Sweet Peas growing in the borders to induce a succession of flowers. I find this better than sowing later for succession, and let the first lots run out through seed bearing. No plants will carry a crop of seeds and blossoms at the same time. If any early growing a few kinds of Peas (including such as are useful for cutting, especially whites and scarlets. Potted the first batch of Frezias for early blooming. Roman Hyacinths for forcing have just come to hand; these will be potted in succession batches for early work. All the stock of forcing bulbs have been ordered. Divided some old plants of Oxalis variegata. This is a very ornamental Grass of graceful habit, very suitable for table decoration. Shifted on young Ferns of various kinds from small pots to those 5 inches in diameter. Put in a lot of cuttings of variegated Begonias of various sorts; the plants are getting rather large for room decoration, and well furnished plants in 6-inch pots are very useful. In potting winter-flowering Begonias at this season, if large plants are required, it is a very easy matter to make them up by placing three or more in large pots. The same principle can be carried out with other things.

4136.—Petroleum and weeds.—One-sixth part of petroleum I find will kill surface-growing weeds when it is applied through a syringe in a proper manner; but it is so difficult to mix with water that it is an uncertain remedy, and an expensive one as compared to an application of one of the weed-killers so often advertised in GARDENING. If it is inconvenient to use the latter, why not apply salt? It is quite as efficacious and as cheap as anything else for small gardens; but it should be used in dry weather.—J. C. C.

4097.—Tropaeolum Fireball.—The variety called Fireball is quite distinct from speciosum. Fireball is a selection from Lobbl, and is a fibrous-rooted kind, and is better adapted for the greenhouse, where, if raised up near the glass, it will flower all the winter. I have never tried speciosum in the greenhouse, but I should say it is better adapted for planting in the open air, and in this district, which is a dry one, it only succeeds well on the north side of a wall or fence.—E. H.

4135. Plants for show in September.—Tuberous Begonia, Scarborough Lilies, Plumbago cespensis, and Bourdianas are all useful.—E. H.

OUTDOOR PLANTS.

VERBASCUM OLYMPICUM.

SOME of the more important biennials, Foxgloves, and, still more notably, the larger Mulleins, have in their short lives two distinct seasons of beauty. The first when the young plant, within its first year of life, has thrown all its strength into the great rosette of foliage; the second, when the garnered vigour has been expended in building up the stately flower-spikes. The engraving shows the Olympian Mullein in the first state, when its leaves, of the palest grey-green velvet, are in their young prime. A plant that has passed midsummer in this state will probably so remain till next spring, the grand circle of leaves, 3 feet to 4 feet in diameter, growing a little more, but retaining its perfect appearance till well into the winter. Frost will destroy the outer leaves, but they will be renewed when the warmer days come, to be followed by the great branching stem, laden with sulphur-coloured flowers.

4123.—A house border.—You could have creepers against your house Veitch's

although I should not go in very strongly for these. Choose also of the Achilleas, the beautiful White *A. mongolica*, *A. Ptarmica* fl. pl., or, better than this, *A. The Pearl*, a lovely summer flower, each like a little rosette, and beautiful on the plant, also useful for cutting. But, firstly, I ought to have reminded you that the border must be well prepared, otherwise success cannot come. In the south position such beautiful Peruvian Lilies as *Aletrismeria areca*, the hardiest of all, may be grown, and a good mass of it is a pleasure to see. *Adonis vernalis* is charming in the spring with its yellow flowers and dense growth, whilst yet also a good selection of the varieties of the *Rosa* *Campion*, *Alysaum saxatile compactum*, appropriately called *Gold Dust*, is smothered with yellow flowers in the spring. Then in the late summer and autumn very beautiful is the *White Japan Anemone*, one of the finest hardy perennials in cultivation. It will provide a wealth of bloom for the house. The lovely *Anemone nemorosa* in variety will give beauty to the border in spring. Get also *Columbines*, *Sweet Williams*, *Phloxes*, *Tufted Pansies* in variety, and they have been frequently noted of late in GARDENING, dwarf *Michaelmas Daisies*, *Erigeron specio-*

to have a warm soil, light, and well drained. In low-lying positions failure is certain to result. Sometimes on a warm nook in the rockery it will bloom well, or in a border running by the side of a plant-house. The best results are got from a bed raised above the level a few inches, and throughout the winter protected by a frame from heavy rains, but in the summer fully exposed and kept dry. It is such a quaint flower that it is worth a little trouble to get it true to character.—O. T.

4159.—**Flower-beds.**—You could make the beds gay with *Tufted Pansies* in good variety, but got decidedly coloured kinds, such as *Archie Grant* (rich blue), *Duchess of Sutherland* (lovely lilac shade), or one of the many whites. Many things go well with them, especially the *Lobelia fulgens*, which is a splendid flower in early autumn, and even when not in bloom its rich chocolate-coloured leafage is attractive. The *Cladiol* would do well, and one bed would look exceedingly well planted with *Fuchsias*, either greenhouse kinds or the hardy *F. Riccarteni*, having in between the *Ostenia candelans*, whose late spikes of white bell-shaped flowers are in perfect contrast to the masses of *Crimson Fuchsia* flowers. One bed would look very well planted with *Carnations* and *Tea-scented Roses*; but the soil must be well prepared. This is a lovely mixture, or you may change it by having the *Roses* to contrast to *Tufted Pansies*. The *Anemone* would do well in the centre, but it is rather robust, and would soon monopolise the space; but even if the bed was composed of nothing else, it would be very beautiful to look at in late summer and throughout the autumn. *Hydrangea paniculata grandiflora* is a fine shrub for such a purpose, quite hardy, and very free, producing large panicles of white flowers. I should try the *Tufted Pansies* and *Roses*.—C. T.

4119.—**Destroying Chickweed.**—The constant use of the hoe is the best, if not the only, way of keeping this pest under. The reason of it is that the ground is so full of the seed that every time it is turned over a fresh crop appears. Keep on hoeing it up, choosing a dry, summer day if possible, whenever it appears, and before it runs to seed (this is most important), and in time the soil will become free from it, although it must be admitted that it is a long and tedious process.—B. C. R.

4140.—**Tuberous Begonias.**—I suspect your plants were treated like many more are which turn out miserable failures in the beds out-of-doors—viz., they are started into growth in a moist and warm temperature, thus rendering the leaves and stems soft and sappy, and unable to bear either sun-heat, drought, or cold winds. Tuberous *Begonias* as bedding plants can be classed amongst the finest subjects for the embellishment of the flower-beds or borders, but the plants must be properly prepared before being finally put out into their flowering quarters. The first week in April is soon enough to start the tubers into growth, and this should not be done by the aid of artificial heat. Cold frames afford the best means of preparing the tubers. At planting time the plants should not be more than 4 inches or so high, and of a sturdy character. The recent hot, dry weather has been all against *Begonias*, even in the best of condition; but these improperly prepared it has been quite the reverse of good. I should advise "H. Harrison" to afford some shade to the plants, either by stretching some tiffany over the plants during the hottest part of the day or by thrusting some branches of such trees as *Sycamore* or *Horse-Chestnut* in the soil among the plants until new growth is apparent, removing the shade by degrees if the weather continues hot and dry. It is wise to cover the soil about the plants with some low-growing subject, such as *Herniaria glabra*, *Sodium glaucum*, or *S. Lydium*, which has the effect of not only conserving moisture in the soil, but forms an agreeable contrast for the bright colours of the flowers above.—S. F.

— It is somewhat strange that the plants refuse to grow; as a rule, they flourish like weeds when planted out in this manner. Have they been watered thoroughly, so as to keep the soil constantly moist? Mere sprinkling, such as too many people consider sufficient, are useless in such weather as this. The only other thing I can suggest is that the manure used was too fresh and rank, which would very likely

Foliage of Olympian Mullein (*Verbascum olympicum*). Engraved from a photograph.

Virginia Creeper, *Gloire de Dijon*, or in your position *W. A. Richardson* *Roses*, *Clematis Jackmani*, the beautiful *C. montana*, *Jasminum nudiflorum*, and *Honeysuckles*. I should not plant *Ivies*, as they are so common everywhere, and in the southern aspect you may enjoy beautiful flowering climbers. Now as to the selection of plants. You may plant for an effect in spring, *Crocuses*, *Daffodils*, *Tulips*, *Ornithogalum*, and other spring-flowering bulbs. Get a few good ones of each section, and the *Daffodils* will last over a fairly long season—if you have the early pallidus *praecox*, then the noble *Horsfieldi*, a splendid trumpet variety, *maximus*, rich yellow; the lovely *Phoenix's Eye*, and the double white *poetiana*. Also get the pretty *Hoop Petticoat*, *Narcissus*, and the *Star*, *Narcissus Stella* and *Sir Watkin*, not forgetting a few doubles. These must be planted in the autumn. Then you could get some *Lilies*—*L. candidum*, *L. umbellatum*, *L. croceum*, *L. auratum*, and *L. davuricum*; but it depends of course upon what you are prepared to spend as to the selection. At any rate, you may select from these. As regards plants other than herbaceous, get some good self *Carnations*; *Pink Mrs. Lakin* (white), *Her Majesty* (the old white), and such beautiful lace kinds as *Modesty*,

sum superbum, the late spring and early summer blooming yellow *Helenium pumilum*, *Achillea*, *Canterbury Bells*, easily raised from seed sown now, *Antirrhinum*, *Forget-me-not*, *Campanulas* in variety, particularly *C. persicifolia*, the white-flowered *Chrysanthemum uliginosum*, *Coreopsis lanceolata*, *Delphiniums*, *Dictamnus Fraxinella*, both the type and the white variety, *Dicentra spectabilis*, also known as the *Lyre-flower*, *Doronicum plani-ginnum excelsum*, *Sea Hollies*, *Funkias* or *Plantain Lilies*, especially *F. Sieboldi*, *Genm miniatum*, *Cypripedium paniculatum*, *Houchera sanguinea*, *Perennial Sunflowers*, *Scarlet Lychnis*, *Lupinus polyphyllus albus*, *Evening Primroses* in variety, *Poppies*, *Polemonium Richardsoni*, *Saxifrage*, *Trollius*, and of course you can make the garden gay with *Sweet Peas*, *Poppies*, *Tropaeolum*, and other annuals. To the above list, which I think you will find quite long enough, but it contains all the best things, may be added the *German Irises*, and double crimson and blush *Paeonias*.—C. T.

4139.—**Treatment of the Mourning** *Centaurea* *Isis*, which I may mention for the benefit of other readers is called *I. rubra*, and is notoriously troublesome to grow. It is essential

account for it. All else being well, water the plants once or twice with a solution of nitrate of soda, one ounce to the gallon, sprinkling the foliage well with pure water immediately afterwards to prevent scalding. A mulch of Cocoanut-fibre or spent Hope would also assist them greatly.—B. C. R.

4110.—**Pansy-cuttings, &c.**—The right time to take cuttings of Pansies is towards the end of August and during the early part of September. Choose wiry young shoots from the base of the plants that have not flowered, insert them in light, sandy soil, and keep moist and shaded till rooted. Tulips may be transplanted at any time after the foliage has completely died away; September is probably the best month.—B. C. R.

4103.—**Layering Carnations.**—Surround the plants with gritty soil; road-grit and leaf-mould, with a little loam, will do. Remove any leaves which may be in the way at the bottom of the shoot, and make a cut with a sharp knife upwards through a joint, and about half-way through the stem. Peg down firmly in the gritty soil, and cover the stem about half an inch or so in depth. Keep the soil moist by watering when necessary.—E. H.

4160.—**A dusty garden.**—I thank you for the information you send with regard to the behaviour of the plants in your garden, as I am just now interested in this question, and I find your experience with some of the flowers is similar to my own. I may add to my previous list the Marguerites as being very satisfactory for such a garden, especially the variety Feu d'Or. This is a strong-growing kind, with light-yellow flowers, that has been in bloom for a month past, and will continue so until frost cuts it down. The leaves being narrow, the dust does not lodge on them very much.—J. C. O.

4124.—**Dandelions on a lawn.**—These can be got rid of in time by keeping the heads out off. It is perfectly true that a hebeheaded root will break out again, but if the process is repeated two or three times the root dies. The heheading, of course, must be done promptly. It will not do to give time for the plants to gather strength after each decapitation. Lawn sand, sulphuric acid, and other destructive substances may be used to expedite the work, but the heheading alone will do it.—E. H.

4115.—**Spiraea japonica roots.**—When the growth of the plants gets too weak to flower well, divide in spring, and plant out in a moist situation, or where water can be given when dry, and let them remain two years to get strong. They may then be potted up and forced again and will generally give satisfaction. But when the roots are divided after flowering, especially if they have been forced, they are not strong enough to flower well the next season. I have divided strong roots in the autumn, but if the roots are much out about in doing so it is better not to force them. I should say either divide in spring, or let them remain two years, or else plant out without dividing; repeat in a pot a size larger.—E. H.

—Yes, divide the roots after flowering, and before planting them out. If they are allowed to remain undisturbed for two years quite small pieces will make good clumps in this time.—B. C. R.

Flowers for dusty gardens.—In GARDENING, July 8th, p. 255, a note appears from "J. C. G." upon this subject, and he mentions a few things, bedders, that he knows succeed well under such circumstances. Two good plants that are not harmed by dust are the Iris in variety and the Fuchsia. I have seen large masses of the German Iris succeed perfectly well in hot, dusty gardens, and this group is so extensive that varieties that offer great range in colour may be obtained. The best is the common blue, avoiding all flowers with shade of delicate colour. The Fuchsia will live well in most spots, and as with the Iris, dust is quickly removed from the smooth surface of the leaf. There would be fewer disappointments if only those things known to succeed well, where the position is trying for most plants, were selected.—V. C.

4122.—**Bog soil.**—Very good Potatoes are grown in the Fen districts, especially in dry seasons. Other vegetables also, such as Asparagus, Celery, Greens, and roots are grown in considerable perfection, in large quantities, for the supply of the Midlands and Northern markets. In some districts now, notably in

what was formerly Whittlesea, there it is quite possible to dig through the bog and bring up clay from below to improve the top soil, and claying is now common in winter and spring.—E. H.

TREES AND SHRUBS.

The Variegated Maple.—One of the most largely planted trees in towns is the Variegated Maple (*Acer Negundo variegatum*, as it is botanically called), and the result is not happy. The tree has very holdly variegated leafage, and rendered so conspicuous that the presence of it results in a monotonous effect. Trees of this character should be planted with the utmost caution, otherwise there is an variety. I do not wish to condemn it—far from it; but must say that when seen in almost every garden in some suburbs it gets wearisome. A few of it quickly add to the beauty of thoroughfares, making a distinct change from the usual run of things. When planted against Copper Beech, or some dark-leaved shrub of similar tone, the effect is rich and attractive.—V. C.

A new shrub.—A charming shrub is the sport from *Spiraea Bumalda*, named Knaphill Crimson, which produces a profusion of crimson flowers, and is very constant. It occurred in the Knaphill nursery of Mr. Waterer, and it is a shrub that should be made note of. The habit of growth is dwarf, like the parent, the plant growing about 2 feet in height. It likes a rather warm position, the soil fairly light and well drained, and being dwarf and spreading may be planted in a group. These dwarf *Spiraeas* are often written of as tender, but this is not the case, except in the coldest spots.—V. C.

4111.—**Pruning flowering shrubs.**—As both Myrtles and the large White Jasmine flower on shoots of the current year's growth, any pruning required is best done during the autumn, or before the first week in March. Myrtle communis, the most generally known and the most useful variety, does not require much pruning as a rule, with the exception of the removal of unsightly branches that have grown beyond a prescribed area. The Jasmine needs rather severe treatment in this respect. When the allotted wall space is covered, the shoots made annually should be cut back to within an eye or two of the base at the time named.—S. P.

—If Myrtles or Jasmynes require much pruning it should be done in spring when the plants are trained; but long shoots may be taken out of Jasmynes any time during summer. Myrtles will hardly require much pruning beyond a little regulation of the growth in spring.—E. H.

4169.—**Lilacs.**—There is no difference in the behaviour of the different sorts of Lilac for such a case as yours. What you have to contend against is the elevated position of the garden and the rough wind that sweeps over it. Whatever you plant should be put in not later than the middle of October, and instead of selecting plants with spreading branches 3 feet or more in height, select those that have a short, sturdy growth not more than 2 feet high. Even these should be rejected if they have not got a mass of young roots. Without the latter to steady them in the ground they are sure to die. As soon as you put in a tree or shrub weigh the roots with large stones, covering all the surface in a circle 2 feet over. You will be surprised how much this will steady them against the wind. I know something of the difficulty you have to contend with, and my advice is that you put in only thoroughly-prepared plants, even if you do not have so many of them.—J. C. C.

—I have always found the Persian Lilac if anything more robust, and certainly more sciliferous, than the ordinary kind, though the growth is not so strong. I fear the soil does not suit the plants. Try putting some manure below the roots, and a mulch on top.—B. C. R.

4104.—**Clipping a Bay hedge.**—Cut the Bay hedge down so as to get a little growth as it again before winter. I think I should rather prune a Bay hedge with a knife, the shears make such a hash with large leaved shrubs. Box edgings also may be cut now, selecting a dull, damp day, if possible.—E. H.

4129.—**Ivy on a wall.**—In respect the soil in which the Ivy is planted is poor, hence the reason of its slow progress. At the beginning of next October take up the roots carefully and well trench the soil, 2 foot deep and about as much wide. Add partly decayed manure freely. If the soil is clay, or otherwise not genial to the roots, add road-grit, decayed vegetable refuse, or old potting-soil freely. Plant the Ivy carefully,

not burying the roots too deep, covering them with some of the best of the compost and mulch the surface with manure, 2 inches thick, afterwards; this will preserve the roots from frost during the winter and keep them moist during the summer. Ivy is partial to moisture both at the roots and overhead when growing freely, therefore too much water cannot well be given when the drainage is satisfactory. Secure the leading shoots to the wall to encourage them to cling of their own accord.—S. P.

4087.—Striking cuttings of shrubs.

—The amount of success to be met with in this matter depends mainly upon the convenience you have and the amount of time you can devote to the work. If you have a cold frame available, or a few hand-lights, you will have less difficulty in doing what you want. As a matter of fact, you will not succeed in striking the young growth of *Deutzias* without giving the cuttings some protection. Fairly hard shoots of this season's growth of such subjects as *Escallonia*, variegated *Holly*, *Roses*, *Honey-suckles*, *Passion-flower*, and *Jasmines* will strike in a cold frame, if the cuttings are dibbled in a bed of sandy soil about the end of this month. Cuttings of the Common Laurel, Aucuba, Box, *Laurestinus*, and *Portugal Laurels* will root freely if they are planted on a sheltered border early in October. To propagate such subjects as *Thujae*, *Cupressus*, and *Euconymus*, you must have some kind of glass protection, and you must have sufficient patience for the cuttings to get well rooted before you move them.—J. C. C.

Ceanothus Gloire de Versailles.—Apart from the original species and varieties thereof, there are now a great many garden forms of *Ceanothus*, between several of whom, however, the difference is very slight. The variety *Gloire de Versailles* is of Continental origin, and has been grown for many years, but as far as my experience extends it is still of the very best and hardiest, which last is of great importance, for in many districts the *Ceanothuses* suffer greatly during the winter if they are not protected by a wall or something in that way. If not cut too severely they, however, quickly recover, and so summer advances many of them will be laden with their plum-like clusters of pale-blue blossoms. In planting the *Ceanothus* see shrubs in the open ground, a sheltered spot should as far as possible be chosen, for the cold cutting winds of early spring often injure them so much as severe frosts in the winter. A free light soil suits them well.—H.

PENTSTEMONS.

It is very disappointing when having raised a quantity of young plants of *Pentstemon* from seed early in the spring, planted them out and had a fine bloom from them in the autumn, to find the winter, either because so wet or so severely cold, has either destroyed the plants absolutely, or has so cramped them that they are almost useless henceforth. Those who have a greenhouse or a frame may get over the disappointment somewhat if plenty of cuttings have been taken off during September and put into pots, stood on a shelf or in some moderately shaded part of the frame, and there nicely rooted. Such young plants potted up singly in the spring and later planted outdoors make capital substitutes for the old plants which the frosts have destroyed. When, however, the old plants do survive the winter unharmed, then the many strong shoots sent up from the stems of the plants produce such clusters of bloom as to excel materially anything that can be obtained from young seedlings or cutting-made plants. But it is not difficult to have, apart from the cutting-made reserve, a quantity of young plants to stand the winter if a sowing of seed be made within the next few weeks. *Pentstemon* seed does not germinate very rapidly and plant growth is rather slow, so that if seed be sown at the end of July or early in August, it is not probable that the seedling plants will be, by the end of November, at all too large to keep, as they are in a frame or under a hand-light for the winter. The best course would be to dibble them out from the seed-bed or pans into a frame thickly or else under hand-lights. When once rooted very little protection will suffice to keep them safe through hard weather. In the autumn these plants, lifted carefully with small clusters of roots

attached and as carefully planted out, will soon develop into strong blooming ones and make a fine display all through the early summer, a spring sowing coming on to make a succession. Practically, Pentstemon should always be treated as

BIENNIALS, but consideration has to be given to the fact that they are not always so hardy as true biennials should be. The Antirrhinum is pretty much in the same boat as is the Pentstemon, for both are somewhat soft-wooded and are apt to die wholesale under the effects of severe weather. Snapdragons are so prolific of seed, that they may be easily raised at almost any time, and although with these, as with Pentstemons, no plants produce such a fine display of bloom as do strong ones that have been safely wintered outdoors, yet dead ones may readily be replaced by seedlings raised by an autumn sowing. As to the raising of Pentstemons from seed, it is best always to obtain a really good stock. There is such a

INDOOR PLANTS.

THE SMALLER-FLOWERED EUCHARIS (E. CANDIDA).

THE more we see of this beautiful bulbous plant the more we are convinced of its great value, particularly for affording an abundant and continuous supply of out flowers during winter. It is not second even in beauty to its popular congener, *E. amazonica*, and, being smaller, it is even more desirable, especially for association with other out flowers. The blossoms are about a third smaller than those of the Amazon Lily, but are of the same waxy texture and snowy whiteness, save the cup, which is tinged with a greenish yellow. It is a vigorous grower, and develops leaves as large or even larger than *E. amazonica*, and continues to produce flower-spikes throughout the winter if grown in a moist, warm plant-house. It may be successfully grown in a good, turfy loam, enriched by

to prevent the soil running among the faggots. Over the straw a layer of last year's leaves is placed, into this the roots of the Violets find their way, they being especially partial to decayed leaves. The soil I use is mainly composed of roadside refuse, with which is mixed a quantity of grit that assists in keeping the whole porous. To this I liberally add decayed leaves with the addition of a small quantity of horse manure partly decayed. This compost is about 9 inches thick. If the soil in the garden is naturally inclined to be sandy add the horse manure and decayed leaves to it simply. The plants are then lifted with a good ball of soil and roots attached, and planted in the frame; the soil is pressed firmly about the roots. When the plants are placed in the frame the leaves are quite at the top of the sides of the frame. In a short time the soil settles down, so that by the time the lights are placed on the plants are within 2 inches of the glass. They should receive a

Flowers of *Eucharis candida*.

wide distinction now between good and indifferent strains, that only those familiar with the former can understand how great is the advance made in the flowers. Once a good strain is secured, it is easy to retain and even to improve it. Something, perhaps much, has been done in the direction of improvement by cross-breeding, but very much also has come from selection, and it is open to any amateur grower of Pentstemons to select the very best flowers, mark them each year, and save seed from these alone. In that way it will be found easy to greatly improve any stock. Any new grower of Pentstemons, however, will do wisely to make as good a start as possible with a good strain, as it is sheer waste of time to go over the ground which others have long since traversed, when the results of their labours may be had in seed form at a trifling cost. Very much improvement has also been effected in the habit of growth of the Pentstemon, but yet there is still room for further progress in that direction. A.

a little well decayed manure. When seen in the form of huge specimens in 14-inch pots bearing a quantity of flower-spikes, often as many as ten and a dozen blooms on each, this plant forms a really lovely sight.

4148. — **Double Violets for winter flowering.**—As the plants are now a good size remove any runners that form between now and September, and keep the plants clear of weeds, which prevents the maturation of the crowns by excluding from them light and air. The best winter quarters for the frame is a sunny position sheltered from north and east winds. Place the frame on two bricks at each corner to raise it above the soil, which is a preventive against the rotting of the frame. At the bottom of the frame I place a layer of faggots or old Pea-stakes for a twofold object—viz., raising the plants near to the glass and permitting of thorough drainage, as I find the development of the plants retarded if the roots are waterlogged. On the wood a thin layer of stable litter is placed

good soaking of water, which settles the soil about them. I omitted to say that in planting into the frame the leaves of one plant should be so near to its neighbour as just to stand clear—that provides sufficient space for each plant. Do not place the lights over the plants until there is danger of frost or continuous rains; even then tilt them at the back to admit air to the plants. The roots make progress, but not the leaves, which is what is required; if many new leaves are made before the April following the crop of flowers is a thin one. Although a few degrees of frost will not injure the Violets when the lights are on, it is not wise to have the leaves touched by it. Abundance of air should be given at all times when the thermometer out-of-doors stands above 35 degs. Anything approaching the plants in detrimental to their welfare. As to watering, this depends so much upon the kind of soil the plants are growing in. In my case I do not find it necessary to water until February, after the thorough soaking the plants receive when first put into the frame.

The state of the soil is the best guide; if it dries quickly by all means well soak it, and be sure this is done in the morning, so that the leaves will be thoroughly dry before closing the frame at night. The frame will need protecting from frost in some way; freshly-gathered leaves or manure answers the purpose for the sides. The glass can be protected by mats, straw, hurdles, or some other means.—S. P.

4154.—**Oleander not flowering.**—A short time ago I went to visit a friend, and noticed a magnificent Oleander in his house in full bloom. I remarked upon its beauty, and lamented that in spite of following the instructions of practical gardeners strictly, I had never succeeded in getting beyond beds. My friend replied, "I know; it was just the same with me for several years, and I was in despair, until I was informed that the plant ought always to stand in water. I tried the receipt, and now I never fail to bloom it." I am now trying this plan myself, and hope it may turn out as well in my case. It is all very well for professional gardeners, who are always at hand, or have men to look after things when they are not, to recommend that such and such a plant shall be kept plentifully supplied with water; but the amateur who has only his mornings before breakfast, and his evenings after tea or dinner, to look after his stock, may easily overlook individual plants with fatal results as regards bloom.—A. G. BUTLER.

4141.—**Heating a greenhouse.**—You do not state the height of the structure, which is an important factor, or yet whether it is a lean-to or span-roof. But in either case 40 feet of 4-inch piping would not be enough to ensure a temperature of 50 degs. in severe weather, and I should strongly advise the addition of another 20 feet, which the coil, if properly set, would work quite easily.—B. C. R.

4105.—**Treatment of Hakea.**—These are New Holland plants, and require greenhouse treatment. The soil should be composed of a mixture of about equal parts fibry loam, peat, and sufficient sharp silver sand to make it moderately porous. As with all plants of this character, it is most important to have plenty of drainage, otherwise they suffer severely from a waterlogged condition of the soil. Too much water inflicts serious injury, few plants suffering more from this cause than such things. There is a host of kinds, and many have been introduced a long time into English gardens. *H. acicularis* was introduced in 1790, also *H. dactyloides*, whilst others were sent over quite early in the present century.—C. T.

4104.—**Treatment of a Passion-flower.**—Either the soil is too rich, the growth is too crowded, or the plant is of a bad sort, and will never bloom well. Numbers of this Passion-flower are raised from seed, and seedlings, as is well known, vary considerably in floriferousness, &c. I incline to the latter theory, as the plants in your neighbour's garden do so well, and, if it is so, the sooner the plant is pulled out and a better one planted the better.—B. C. R.

4171.—**Double Begonias.**—Many of these Begonias, and the doubles especially, have a way of dropping their buds in a very aggravating manner. With some (seedling plants particularly) the fault is inherent, but beyond this it chiefly depends on a vigorous root-action. The doubles prefer a rather more firm and substantial compost than the singles—too much leaf-mould is not good—and it should also be composed somewhat more firmly together. Water must be given with care, and only when the soil becomes slightly dry, then affording a thorough supply. Do you use any stimulants? A very little scab dissolved in the water is excellent, and also a sprinkling of the silicate manure now and then will be found very beneficial.—B. C. R.

4173.—**Uses of a frame.**—If you have a sufficient number of plants you may fill either of the frames with Violets in September, but, of course, the plants will have to be prepared to be satisfactory. The large frame may be sown with Early Horn Carrot-seed early next month (August), and the lights put on about the middle of October. You would be able to draw a good supply of young roots from so large a space through the greater part of the winter. You will gain nothing by trying to get the Carrots earlier; they will not submit of being

buried, but will have their own way. Such bulbs as Daffodils, Hyacinths, and Tulips can, however, be successfully grown in the frame, and then removed to the greenhouse or window. Cold frames are also useful for wintering choice Pansies and Cereals. You had better not risk your *Echeverias* and *Calceolarias* in Celery trenches as you suggest, or a hard winter may come and kill the lot.—J. C. C.

4145.—**Blue Hydrangeas.**—To every bushel of ordinary compost (and this should not be too rich), add ½ lb. sulphate of iron, powdered rather fine. Thoroughly well mix the compost, and press the soil about the roots firmly. Hydrangeas do not require much pot-room, so they flower more freely when the roots are somewhat confined. When new growth is perceptible in the spring, supply the plants with warm water, dissolving half an ounce in 1 gallon of clear water, and applying it alternately with clean water or an occasional dose of liquid-manure.—S. P.

—Plant in peat, and I think you will get the desired result. I have not tried the experiment myself, as I have been satisfied with the pink variety.—A. G. BUTLER.

4135.—**Balsams, Petunias, and Begonias.**—You ask for information which it is difficult to give, because so much depends on the vigour of the plants and the temperature prevailing. You ask, indeed, for information the correctness of which can only be obtained by practice and knowledge. You must understand, first, that double flowers take longer to develop than single ones. Seeing that it is better to leave off taking off the flowers a little too early than too late, you had better allow three weeks for the blossoms to expand on the plants you mention.—J. C. C.

4172.—**Aparagu plumbeus.**—A cool greenhouse is not a suitable place for these plants in the winter. No doubt they received a check then that they have not yet recovered. If they are rooted out in the fresh soil, a little soot in the water now and then will render the foliage of a healthy colour, and they might be watered two or three times with a weak solution of nitrate of soda (½ oz. to the gallon). Otherwise you must leave them alone. A gentle bottom-heat might be of service.—B. C. R.

4146.—**Streptocarpus hybrida, &c.**—I find these plants do not form any seed in the early part of the summer, but do so later on. If you have plants in bloom now, and you place them in an airy place in the greenhouse they will probably give you a little seed; but it will not be much, as the blossoms appear to want fertilising to produce seed freely. You must not dry off the plants as you would Begonias, although they want much less water in the winter than in summer. The plants are at their best the second or third year, after that they have an awkward way of dying off in the collar without any apparent reason.—J. C. C.

—Fertilise the blossoms while expanded, using a small, soft camel-hair brush, and keep the plants in a moderately-dry atmosphere, with light shades from hot sun only. My plants retained a few green leaves during the whole of last winter, but then they were quite young seedlings, and I understand the old roots may be stored away like Begonias. I should, however, keep them in a temperature of 45 degs. to 50 degs., on a shelf or the like, giving only enough water to keep the soil barely moist, and then they can please themselves about going completely to rest or not.—B. C. R.

4131.—**Boronia megastigma.**—No doubt this plant could be easily raised from seed, but the difficulty, I imagine, would be to obtain this. Sow in extra well-drained pots or pans of very sandy peat, sifted fine on the surface, and with a little charred leaf-mould on the top, and keep moist and shaded in a warm greenhouse. April is the best month.—B. C. R.

—There is less trouble in raising seedlings, but the seedlings are not so compact in habit of growth, and do not flower so soon as plants raised from cuttings, but without proper concealment, such as bell-glasses, &c., *Boronia* are difficult to strike. Sow seeds in spring.—E. H.

4116.—**Phormium tenax.**—This flowers in greenhouses in this country, and possibly out-of-doors in the extreme southern counties, where it may be trusted in the open. It is not a thoroughly satisfactory plant out-of-doors, except in peculiarly favourable situations, and is safer in the greenhouse or conservatory, in which it makes a distinct feature—a change from the usual view of things. It should be placed in the open during the summer months. The

flowers are of a lemon colour, and the whole aspect of the plant is vigorous, the leaves of noble growth, strong, and pleasingly arched. If you have a large garden you may use it with advantage in the summer arrangements, such as in the centre of a large bed of sub-tropical subjects. The variegated form is very handsome, and a few large, or, for that matter, small species are very handsome. If your examples are in good health they will bloom in time, but it is for its foliage and fine habit that the New Zealand Flax is so largely grown.—Q. T.

4018.—**Petting Caotli.**—I should not pot these until the autumn, and do not turn them out-of-doors. The last of my Caotli are now blooming (with one late flower) for the third time this year. I have a grand show of *Cerena*. I keep them in heat all through the year, but in the winter they rarely get more than 50 degs., and hardly say water.—A. G. BUTLER.

4113.—**Alco-carbon light and plants.**—I use this light in my conservatory, and frequently have it full on all the evening in the winter months, but it never injures one of my plants in the least. I also have an alcohol three-globed chandelier in my drawing-room in which I have at least one Fern in a pot and a large *Fern*, the doors of which are usually open more or less; no evil effects have resulted.—A. G. BUTLER.

ROSES.

NOTES ON ROSES.

THE ROSE APHIS.—This is a pest that affects those Roses growing on poor ground in particular; and as many amateurs are troubled with it, a few notes of remedies that have been found of value may be made. It increases very quickly, and to arrest the pest at first is always the better way. Clean water will work wonders, with good syringing when the pest is seen, before it has made much headway, and will obviate the need of insecticides. I always think that those who have not many Roses, and gardens of limited size, value a few brief remedies for the suppression of insect pests. Quassia-chips are valuable to keep down the Rose Aphis, and often used; but one of the best insecticides is composed of 1½ lb. of soft-soap, and Tobacco-juice from 4 oz. of Tobacco placed in hot water. This should be added to 25 gallons of water. An excellent preparation is one part of soft-soap to the eighth part of boiling water, then adding sufficient paraffin to make it of a moderate degree of strength; but carefully avoid making it too strong, otherwise mischief will ensue. The soft-soap and Tobacco is the safer preparation.

THE ROSE SEASON.—This is by no means an ideal season for Roses. The flowers at the exhibitions have been very poor, and some of the leading growers have been unable to exhibit. It is not often that this is the case, but perhaps there will be a fair autumn display. If so we shall be rewarded. The best varieties this year are those of the hybrid perpetual class, the dark-coloured kinds in particular, such as *Xavier Olibe*, *Horace Vereet*, and *Lois Van Houtte*. *Gustave Piganees* is one of the chief prize-winners, and although quite a new Rose, it is now largely cultivated. The flowers are of immense size—quite distinctive in this respect—and crimson in colour. Another conspicuous variety has been the now famous *Ulrich Brunner*, which is grown largely, and is a good Rose either in the garden or for exhibition. Amongst the Tea-scented class *Ereest Metz* and *Souv. d'Elise Vardon* have been of note.

TWO NEW ROSES.—Readers of *GARDENING* will be doubtless interested in two new Roses of Messrs. A. Dickson and Son, Newtownards, Co. Down, Ireland. One can only judge of them as shown, but they each received a gold medal at the recent exhibition of the National Rose Society at the Crystal Palace. One is named *Marchioness of Londonderry*, and is a large flower, ivory-white, full, and very promising, also strong in growth. The great merit of these new Roses from these raisers is their very sweet fragrance. *Mrs. Sharnan Crawford* is the name of the other; it is shining rose and silvery-white flower, very sweetly scented and distinct, whilst the habit of growth is robust. A gold medal was also given to *Crimson Rambler*, a beautiful new *Polyantha Rose*, the flowers deep-crimson in colour individually, and very showy. They are produced in large clusters, and the plant is very robust in growth. It is a variety quite unique for colour and freedom.

A CHARMING TEA-ROSE.—A very charming class is that known as the *Chius*, and one of the

brightest of all is the variety named *Mina Lauretto Massimey*, which is remarkably free, and has very deep rose-coloured flowers, which make a pleasing display. All this section should if possible be grouped in distinct beds, where they are seen to full advantage. The common *China la* of note, known by its free display of pink flowers, whilst others of note are *Cramoisi-Supérieur* (deep crimson, the flowers full and produced freely), *Fabvier* (brilliant-scarlet), *sanguinea* (intense crimson), and *Little Pet*, which has small white flowers. These classes of *Roses*, the *Chinas*, *Polyanthas*, *Bourbons*, and other sections, are not made enough of in English gardens, but it is not for want of beauty. Both the *Chinas* and *Polyanthas* are amongst the gayest of flowers, and when there is sufficient space in gardens should be boldly grouped.

V. C.

GWN-ROOT ROSES.

I wish to give you my experience with own-root *Roses*. I purchased six each of the following varieties from a highly respectable dealer: Sir J. Paxton, Anna de Diesbach, and John Hopper.

my trees; the grub spared two buds only, which were no bigger than those on the other standards of the same variety which had not been disbudded. I wish to be informed on another point. I have been to four different florists for the same standard *Tea Rose*; in three cases I paid 3s. 6d., to which was added in one case a charge for packing, and in two cases I had to pay the carriage; the fourth tree I paid 2s. for, and it was delivered free; this turns out the best of the four; all four plants are equally well worked, and what I want to know is whether one is supposed to get a better strain for the 3s. 6d. than the 2s.? All my own-root *Roses* were infested with green-fly, while the standards and the bushes worked on the *Brier* only had the usual amount. In addition to the own-root *Roses* mentioned I had four each of the following, also own-root: *Red Gloire*, *J. Margottin*, *Madame I. Periere*, and *Souvenir d'Elise*; these never bloomed and gradually died off, while those varieties stood next to them, worked on the *Brier* stock, flourished. I have done with own-root *Roses*.

KEW.

is *Cheshnut Hybrid*. This bears large red flowers, and is a good climber. Then there is the *Red Glory*, but the flowers are not fragrant. *William Allan Richardson* (colour orange-yellow) is a good climber. *Révo d'Or* is also good, but I should say too much like *Gloire de Dijon* to suit you.—J. C. C.

4165.—**Hardy climbing *Roses***.—It is to be regretted that the *Tea Roses* are not to be depended upon with you, as your wall is just the height to ent them. I am afraid the strong-growing cluster *Roses* will not suit your low wall. Some of the Chinese varieties will, however, do admirably, including the common pink one and *Fabvier* (scarlet); *Souvenir de la Malmaison* is also suitable. Beside those, you may have such *Hybrid Perpetuals* as *General Jacqueminot*, *Magna Charta*, *Gloire Lyonnaise*, and *Baronne Prevost*.—J. C. C.

4130.—**Grafting *Roses***.—The best time to graft *Roses* is in spring—February and March—and the best place for them when grafted is a close shaded house or hut where there is a plunging bed. Graft on the roots of the Common *Brier* and plunge in the bed till the graft starts into growth, then gradually harden and move to the greenhouse, and plant out in beds. Whip-grafting is the simplest and best method of grafting.—E. H.

4149.—***Roses* in an unheated greenhouse**.—In what part of London do you reside, for you should remember that *Roses* and smoke do not agree at all, and unless your garden is in quite an outer suburb it will be much wiser to give up the idea of *Roses* altogether and go in for *Carnations* or something that will be more likely to succeed. If, however, the atmosphere is moderately pure, *Roses* may be grown well in such a structure and without any heat. I should advise planting out, say, a *Maréchal Niel* and a *Climbing Niphetos* at either end of the house, training the growth thinly over the roof, and then you could have a couple of dozen others either in 6 inch or 7-inch pots or planted out in a raised and well-drained border along the front of the house. *Gloire de Dijon*, *Céline Forestier*, *Hémère*, *Niphetos*, *Belle Lyonnaise*, *Isabella Sprunt*, *Souvenir d'un Ami*, and *Mme. Faloot (Teas)*, with *La France*; *Mrs. J. Laing*, *Gen. Jacqueminot*, *Victor Verdier* and *Alfred Colomb* (H. P.'s), are good sorts for a beginner to try, or for any purpose of this kind.—E. C. R.

CHRYSANTHEMUMS.

SINGLE CHRYSANTHEMUMS.

Few plants are better adapted for the amateur grower who has a limited space at command, as they are, generally speaking, naturally dwarf and bushy in habit, and the shoots do not spread out so much as these of other varieties of *Chrysanthemums* do, but are erect in growth, thus greatly economising space. They produce their elegant blossoms in clusters most profusely. As a class, single *Chrysanthemums* always deserve a good place in the schedules of our *Chrysanthemum* societies, and at least two classes might with advantage be reserved for them—one for flowers in trusses out from the plants (say three trusses of each variety), and the other for specimen plants as naturally grown for decorative purposes. The cultural details requiring attention in the management of single *Chrysanthemums* are precisely the same as for those of other kinds grown in a natural manner. Some desirable well-proved kinds to grow are as follows, and the number given will be sufficient for even the largest grower of them. Of course there are many new varieties of great excellence, description of which can be had in any grower's catalogue. The first fifteen named in the list are the best suited for exhibition. I place them in this order to prevent a repetition of names; though all are suited for growth as bushes, yet the flowers of some are too small to be considered exhibition varieties; *Jane* (syn., *Soowflake*) I must place at the head of the list for its lovely form of flower. The colour is white, the petals twisted in a graceful manner. It grows strongly, carries good foliage, and is altogether a gem. As a comparison to this I name *Admiral Sir T. Symonds*. The flowers which droop slightly, are of a bright orange-yellow; most effective in a pot state. These mentioned below are also good kinds. *M. A. is Mout* (amaranth crimson, very showy),

Flowers of *Chrysanthemum* "White Dais." (See page 292.)

These all did well, though the blooms were very small. *Blush China* bloomed, but attained no size. The others, *Félicité Perpétuelle*, *Aimée Vibert*, and *Révo d'Gr* have never shown any sign of bloom, though they made rampant growth. At the end of the first year half of the plants which had failed to bloom were cut back hard, the other half being only moderately pruned; there has been the same result. My other bush *Roses* on the *Brier*, and the three first-mentioned own-roots, have done well. I have also a very fine standard *Aimée Vibert*, purchased from the same florist, being the only one among a hundred other standards which shows no sign of bloom. Is there any peculiarity about this *Rose*? Now as to disbudding. Does disbudding produce large blooms? I took two standard *Barenos Rothschilds*, one I disbudded to three buds, the other I let alone—result, sixteen blooms on one tree, three blooms on the other. There was no superiority in the three blooms upon the first tree as to size; situation and treatment the same for both. An amateur enthusiast told me that disbudding was useless. It should be left to *Roses* which should on no account be interfered with. He insisted on trying his theory on one of

Rose Gloire de Dijon.—No one can regret more than I do that I have worried the mind of the *Rev. S. Reynolds Hole* about the value of this *Rose* for growing under glass (see *GARDENING*, July 15th, 1893, page 278), because I have many times sat at his feet with pleasure and profit when he has discoursed on *Roses*; but in this instance I must really beg to differ. I grant that no other *Rose* flowers so freely or over so long a time as *Gloire de Dijon*, but that is not all that is wanted in a flower that occupies so much space. If it was so, how is it that twelve of *Maréchal Niel* is planted where only one of *Glory* can be found? This fact proves that the majority of people regard *Gloire de Dijon* in the same light as I do—that there are better *Roses* for growing under glass. I admit, however, that when I peened the sentence referred to I may have had the commercial aspect of the question strongly impressed upon my mind.—J. C. C. [ERRATUM.—In the note by the *Rev. S. Reynolds Hole* referred to, it should read "Canuton," not "Taunton."]

4133.—**Climbing *Roses***.—If you had not rejected a scented *Rose* it would be easy to answer your question. The best sweet-smelling *Rose* as distinct from *Gloire de Dijon*,

Effies (a curious mixture of chestnut and claret, the florets very long), David Windsor (bright chestnut red), Lady Churchill (brick-red), America (hush, large flower), Mrs. Willis (white, suffused with pink), Helianthus (bronzeyellow), Puro Gold (as its name implies), Croshed Strawberry (as its name implies), Patience (amarant, tipped with white), White Perfection (pure white, of capital form), Oriflamme (reddish-brown), Mrs. Duke (pale-lilac), Mrs. Langtry (pale-pink), Lady Brook (bright yellow, Buttercup form), Meteor (dark), Oscar Wilde (dull brick-red), Miss Gordon (light-pink, with long, drooping florets), White Daisy (figured on p. 291, a pure white variety, with a yellow disc in the centre), Miss Lala Martin (small pink), Elsie Mand (white, free flowering), Miss Rose (dwarf in habit, pink). The last three named are late-flowering kinds. E.

MILDEW ON CHRYSANTHEMUMS.

The extended heat and drought has rendered the atmosphere so arid that it has been all in favour of the spread of this fungus. I find that the usual sulphur remedy is not nearly drastic enough in its influence to check the progress of this parasite, and it is therefore necessary to resort to other means. Mildew, as a rule, in the ordinary way attacks the upper surface of the leaves of Chrysanthemums, but under such favourable circumstances for its propagation the underneath parts of the leaves are in an equally bad plight. As this pest quickly spreads over the greater part of the foliage of one plant in a few days if not arrested, I would advise amateur cultivators to closely inspect their plants to see if they are at all affected, and if so I would advise them to lose no time in following the plan I am about to detail. Place 2 lb. of sulphur and 2 lb. of lime, which has not been slaked, in 10 quarts of water, and boil for twenty minutes. For syringing the plants use 2 wineglassfuls of the mixture to 4 gallons of clean cold water. A "Stott" syringe is the best instrument to apply the mixture with; by the aid of the sprayer which this syringe is fitted with the liquid can be forced in any direction, thoroughly wetting every part of the plant. If a slight discoloration of the leaves follows from the sediment of the mixture it will not be injurious, and will wash off in time by the aid of rain and the syringe. E. M.

4170.—**Treatment of Chrysanthemums.**—As you require blooms of the finest quality your method of treating the plants has been correct. Had you followed out your last-named suggestion, removing the had only, you would have had three times the number of blooms, but inferior in quality. Very few varieties indeed are there that will come to perfection when allowed to develop more than three buds on one plant. Certainly not of the large-flowered sorts, of which Mlle. Marie Hoste or Etoile de Lyon are examples. Remove all side shoots that push from the nodes below where the bracts occurred, as some varieties have a tendency to make much growth in this manner, it can only be at the expense of the main shoots, weakening them. The prompt removal of surplus shoots concentrates the energy of the plant into the selected branches.—E. M.

— You have done quite right; if all the shoots had been left there would be nice flowers on each plant—for too many. No doubt it will be a very early season for these plants, and if the buds are taken too soon they will be useless.—E. C. R.

4142.—**Chrysanthemums for show.**—I presume you mean—may you continue to stop the shoots until the end of July? This is what your query suggests, although it does not say so. If I am correct in my surmise my advice is not to top them any more, but induce them to grow uninterruptedly, making breaks of their own accord. If not already done the branches should be got into position, as they bend so much easier now than two months hence. The bending of the shoots will not be so much exposed either, as the leaves will hide the bent parts so much better than the bending is done early.—E. M.

4134.—**Old mortar and garden soil.**—Old mortar broken up fine will do good in your garden, but it would do more good in a flower-pot soil. Do not, however, be afraid to use it, as anything fresh is valuable in an old garden. You

may spread it on the surface over the roots of fruit-trees and Vines, and lightly fork it in. You will find early Potatoes come out very clear and free from scab if the ground is liberally dressed with the old mortar.—J. C. C.

ORCHIDS.

CATLEYA SCHOFIELDIANA.

I HAVE from "Mr. C. Jamieson" a magnificent flower of this Cattleya, asking for its name and its native country? And it is such a beauty that I feel constrained to say a few words respecting it. This plant first flowered in the garden of Mr. Law-Schofield, at Rawtenstall, near Manchester, about ten or eleven years ago, and Reichenbach dedicated it to the grower; but since then it has been reduced to a variety of *C. grannosa*, about which I am somewhat doubtful. But, however, be that as it may, this is a very fine kind from a gardener's and an amateur's point of view, for it has a large flower, therefore it has this in its favour; and its colours are both rich and striking, so that it can compete favourably on all points, and it makes up a grand display just at the time when the Orchid flowers, as a rule, are about the shortest and dullest. Especially is this the case in the present year of grace, things being a month earlier, as a rule, than is usually the case. Mr. Schofield, I think, imported this plant in the first place himself, but from whom it came, or who imported it, matters little. Soon more were brought to light, and now a batch of this Cattleya can be brought home, it appears, with as much certainty as any other kind, so that I cannot think it can be even a variety; but we descend from generalities to specialities. Now, this kind, although so beautiful, requires some care to keep it well and in good health. I do not mean to infer that it wants more heat, or more drying, or more anything, than I have so frequently told you that Cattleyas do want, but these requirements must be strictly attended to. The plant will grow along with *C. Trianae*, so that it cannot be said to require a great heat. It may be potted in about the same soil with good drainage; but what is most important is to keep it just moist enough to prevent the bulbs from suffering from drought, for if this is allowed to come on the plant requires a long time to pull round again, and at the same time overwatering must be as strenuously fought against; but everything must be done to make the slender stems as vigorous as possible, and to preserve its large leaves in perfect order. The flowers are produced mostly two on a scape, these each being 5 inches, sepals and petals nearly equal in size and colour, although the petals are somewhat broader. They are thick and fleshy in texture, having a ground-colour of rich Indian-yellow, upon which are a profusion of streaks and spots of crimson-purple. Lip three-lobed, the side lobes erect, creamy white; the middle lobe obovate, which, with the fimbriated reniforme, is of a beautiful bright magenta-purple, and which is covered by papule, and it also has a marginal border of white. No more beautiful and useful Cattleya can be grown, and I would urge all my readers that are Cattleya growers to take the advice of old "Matt." and add it to their collection in the shortest possible time.

MATT. BRAMBLE.

SCUTIOARIAS.

I HAVE forgotten the name of the gentleman to whom I made a promise some few weeks ago respecting these plants, through his letter being mislaid. However, he is not forgotten. Very little is known of the few Orchids which constitute this genus, which were formerly known as *Maxillarias*, but some differences in the organs of the flowers caused Lindley to constitute a new genus for them under the name by which they are now known by Orchid growers, and which has been derived from their leaves—thus *scuticaria*, a whip, from the resemblance of them to a whip. They are plants which require to be grown on a block of wood, and to be firmly fixed there with some stout copper wire, and the plants should be firmly pecked with Sphagnum Moss, which, whenever seen to be decaying should be replaced, and fresh Moss given. This may be easily done without injury to the roots. They

like the very hottest place which can be given them, with full exposure to the sun, excepting when they are in bloom, and then a little shade will serve to prolong the flowers in their beauty. They are not new plants, for S. Steell was introduced from Demerara nearly sixty years ago, and it was again found in that country in 1844, whilst the other kind was imported from Brazil, flowered in the great exhibition year of 1851, and although we only recognise the two species, I have little doubt but there are more kinds to be found, but from some cause or other Orchid growers have discarded these plants from their collections, but, as before stated, both of the known kinds require the very hottest place in the East Indian house, with a good moist atmosphere in the summer season, and at no time in the year should they be subjected to the drying system, for naturally they grow on the trees that overhang rivers.

S. STEELI (the kind sent) is frequently called the Shoe-lace Orchid. Its rounded leaves are frequently 3 feet to 4 feet long, tapering to a point. They are pendulous, and, therefore, it will not grow in any other position but hanging from a block of wood. The flowers are large and beautiful, frequently each 3 inches across, but standing upon short peduncles near the base of the leaves. They have a light yellow ground colour, freely spotted reddish-brown; the lip is of a darker yellow, streaked and spotted in the same manner as the sepals and petals. These are produced either singly or in pairs, and more rarely three are produced upon the same stem, and they are very fragrant. Now, have I not said enough to induce my readers to grow this plant?

S. HADWENI is a different plant, but of the same habit. Its leaves, however, are seldom more than a foot long, but sometimes they reach 18 inches. The flowers are more erect than the previously named kind, the colours much the same as Steell, but less bright and showy. The lip is culate, white or pale-yellow, spotted with flesh colour. It is a very beautiful plant, and, as well as Steell, should be grown by all having the convenience.

MATT. BRAMBLE.

DENDROBIUMS CRYSTALLINUM AND BENSONIÆ.

FLOWERS of the first species come from "J. Acstin," asking to know something about it? This plant was introduced by the Messrs. Veitch, of Chelsea, and it was first flowered by them about twenty-five years ago. I suppose it is one of Mr. Parish's discoveries, or, perhaps, it was one of the finds of Colonel Benson; at any rate, it comes from the mountains in Burma, which is the great country for beautiful Dendrobies. I recently obtained a flower from a celebrated collection, so that I have no hesitation in naming it, which otherwise I might have had some hesitation in doing, for it has become rare in English collections. "J. A." tells me he has two plants that grow out of a lot of D. Bensoniæ, which is not doing well with him; but this kind, of which he sends me two flowers, grows kindly and well. This shows that there is no reason why the D. Bensoniæ should not also do kindly; but perhaps you have starved it from want of water during the winter season. I have found that this plant thrives best in very small pots, and these should be well drained and the roots lightly covered with Sphagnum Moss, and also I have found it to dislike being disturbed; therefore, I generally leave them in the same pots for years, merely giving them a little fresh Moss each spring; but, then, I grow these plants cool in the winter, and just moist enough to keep the bulbs in a nice, plump condition. The thermometer may run down to 55 degs. at night without doing them any harm. Most of my friends and neighbours winter this species in 10 degs. more heat and keep it thoroughly dry, so that the bulbs wither, and each year as it comes round the plants get smaller, until they give up the ghost and depart; and I expect this has been the cause why D. crystallinum has become so rare. It should be grown in small hanging-baskets, for when it grows well the stem-like bulbs attain a length of about 18 inches, and they become pendulous. Let the pans or baskets be well drained, and do not cover the roots with too great an amount of soil. During the summer months let the plant have an abundance of

water, both to its roots and overhead, from the syringe; and if the plants be well potted, the drainage will not allow these plants to suffer from overwatering; and in the winter rest them cool, keeping them just fairly moist. This is a very pretty species. In the flower now before me, which is over 2 inches across, the sepals and petals are waxy-white, the petals being broadest and tipped with purple; the lip is yellow at the base, in front of which comes a zone of white, tipped with purple, and if you take a good, powerful glass you will see the point which its name is derived from, for the anther-case is furnished with numerous crystalline points.

MATT. BRAMBLE.

ONCIDIUM SPHEGIFERUM.

A PORTION of a scape of this species comes to me from "E. Kavanagh" for a name, &c. Well, this plant is one of a natural group of Orchids known as belonging to the section pulvinatum. It is a plant with a stout, oval pseudo bulb, with somewhat sharp edges, bearing a single pale-green leathery leaf, which, when mature, measures some 9 inches long. It makes a long branching spike of bloom, which oftentimes climbs to 4 feet in length, bearing many flowers. It differs from pulvinatum in the long claw to its lip, whilst the bright orange blossoms readily distinguish it from the group to which it belongs.

remained scarce for some time; but it may have been mixed with *O. divaricatum* and *O. pulvinatum*, and thus the right name of the plant only was lost or hidden; but the flowers that came to me from "E. Kavanagh" are of the true plant, having the tips of the sepals and petals rich orange-yellow, their bases being stained with reddish-orange; the lip is somewhat fiddle-shaped, three-lobed, side lobes spreading denticulate at the edges, the front lobe with a long claw, the blade lobed in front, and with the edge plain, the whole being of a light-orange with a papillose crest. This is the plant which I think I am quite right in saying is the true sphagiferum of Lindley, and I hope my friend will use his care to keep it, and to keep it well distinguished by a label, which I am sorry to say I have not found to be largely used in his part of the kingdom. It will grow very well with other stove-plants, requiring only a little extra care to keep the plant just nicely moist, and never letting the thermometer fall below 55 degs.

MATT. BRAMBLE.

THE KITCHEN GARDEN.

CARROTS AND THEIR CULTURE.

LAND that has been freshly manured is not suitable for Carrots. It causes the roots to fork

roots are in a manure-heap, is most likely the cause of the fruits being unsatisfactory, or it may be that they do not get enough. Cucumbers are moisture-loving subjects when the drainage is perfect, and it is surprising what a quantity of water they will take when growing freely. Too heavy a crop is also the cause of failure. The plants are crippled, and must then show the want of strength in some way. Some varieties are so free as to set the fruit in clusters of three and more at one joint. If the plants are allowed to continue doing this, little wonder need then be expressed if they exhibit signs of distress. Thin the fruit to one at a joint where they come in clusters. Want of warmth in a regular manner would cause the fruit to turn yellow, or there may be some objectionable matter in the soil, or too strong a dose of some powerful stimulant may have been given to them. From the foregoing reasons it will be seen there are many things to account for the defects which the fruit exhibits. Water that is tepid ought always to be used. Cold water direct from tanks, underground wells, or from water-companies' pipes should never be given to Cucumbers before airing it, or warming it in some way. The regulation of the growth is an important detail in culture. The shoots ought never to become crowded so much that the leaves are rendered weak and unable to perform their natural functions. During summer, and when the weather is warm, a little air given to the plants by tilting the lights at the opposite end from which the wind is blowing, about eight o'clock, will be the right method to pursue, increasing it as the outside temperature ascends. A thermometer in the frame, and kept at about 70 degs., with air admitted, is a good guide.—S. P.

4143.—Tomatoes not setting. — Hackwood Park is a better setter than Ham Green, and produces larger trusses; but than you do not get the quality in the former that the latter possesses. The weather has been very trying for Tomatoes of late, at least, where grown under glass; it has been absolutely necessary to ventilate as freely as possible, and what with the wind, the sun, and the extremely dry atmosphere, it has been almost impossible to keep the plants moist enough to enable them to set all their blooms. Such, at least, has been my experience, and I have never known the fruit set so badly before under glass. Try syringing the plants twice or thrice daily.—E. C. R.

A note on Potato disease.

—Readers of GARDENING who have not read particulars of the new remedy for Potato disease may be interested in this note. The present year, so far, has been most favourable to this crop, but, of course, one never knows if a long spell of rain will ensue, bringing with it a repetition of the Potato disease. Doubtless many readers of this journal have acres of Potatoes in their keeping, and it is therefore important for them to know that the Bouille Bordelaise is an excellent safeguard against the disease. The French were amongst the first to undertake experiments with this preparation on a large scale, these being under the direction of the great French chemist, Dr. Aimé Girard. Large seed firms in England made experiments, and I personally saw those of Messrs. J. Carter and Co., High Holborn, carried out. I was much struck with the efficacy of the treatment, and the experiment was made on a field of less than an acre. Ten long double rows were planted on April 8th, last year, and the drills 36 inches apart. This permits of the sun's rays penetrating the bed. Now the mixture used to dress the various plots was called Bouille Bordelaise, and made up of 22 lb. of sulphate of copper, 22 lb. of unslaked lime, and 100 gallons of water. This piece of ground was split up into four portions, so that two could be dressed, and the others not touched at all. The preparation gives above sniffes for 1-acre of Potatoes. It may be interesting to mention that the sulphate of copper used was of

OUR READERS' ILLUSTRATION: Carrot "Market Favourite." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. N. Blake, Bedford.

Curiously enough, I have seen this plant under the names of *O. divaricatum*, and also of *O. pulvinatum* and *O. sphagiferum*, all in one collection, and when I had separated the last-named plant from its mixed and entangled state, and made the other names apply to their right plants, the owner of the Orchids, instead of thanking me for my trouble, simply had the impudence to tell me it was all very well for me to say such and such was the case, but he very much doubted if I knew anything about it, and he wished that he had not got me to pull them about; to which I replied that I could soon put matters straight, which I did by taking my names out of the pots, washed him good-day, and have never since paid him a visit. This was about three years ago, and as the owner is a reader of GARDENING, he may learn why I have never made a call since the time when he asked me to help him out of the muddle he had got into with his plants. One likes to be treated with civility, and generally gets it, too, for there is a sort of freemasonry amongst lovers of plants and natural history, which soon begets friendship; but now and again one comes in contact with a man pretending to love these things, and one finds out that is not really so. I have never until now been asked about this species since, or I should in all probability have recorded the circumstance. This plant was cultivated by the Masars, Loddiges fifty years ago; but it

and the Carrots to grow large and coarse. We always give our Carrot bed a good dressing of charred material from the rubbish-heap, mixed with refuse soil from the potting-shed. This is applied after the ground has been deeply cultivated in winter to the depth of several inches, and come time when the surface is dry it is forked in. If maggot is dreaded, a good top-dressing of soot and lime is given at the same time. The middle of April is quite time enough to sow the seeds, and the drill system is the best because of the facilities thus afforded for surface stirring. Many of the principal seed firms now pass Carrot seeds through a machine, which effectually clears away their beard, and makes their distribution when sown regular and easy; but where this is not done, rubbing the seeds between the hands with a little sand intermixed will effectually separate them. Draw the drills half an inch deep and 15 inches apart. Firm the land well before sowing if dry. And Carrots should not be sown in wet weather; better wait till the surface is dry. The best kinds for the main crop are the half-long Carontan and James' Intermediate. A Carrot largely grown for sale is the one here illustrated and known as Market Favourite; it appears to be a very well selected form of the Red Intermediate. H.

4144.—Unhealthy Cucumbers.—Too much moisture at the roots, especially when the

98 per cent. purity, and the Macleesfield patent sulphate of copper. The first and third quarters were dressed with the Bouille Bordelaise on July 11th and August 2nd, and the second and fourth left undressed. Both under and upper surfaces of the leaf were thoroughly dressed with the preparation, and the results were most gratifying. In those plots left untouched the disease appeared early in September. In the dressed plots the weight of the tubers was 58 cwt., whilst in those undressed it was 39 cwt. 2 lb.; whilst the unsoaked tubers in the dressed plots amounted only to 11 lb., in those undressed it came to 6 cwt. 3 qr. 11 lb. So far as sound tubers went, there were about 2 tons per acre more than in the undressed portion. The two plots, it must be remembered, were less than half an acre, and the tubers were of better quality. This is a good proof of the great value of this preparation for the prevention of the Potato disease, and there is no great expense attending it. Those, therefore, in past years who have lost much of their Potato crop through the disease should make a note of the above particulars.—V. C.

4132.—Treatment of Seakale.—If the crowns were all cut over in the usual way nothing more is needed beyond thinning out a weakly one here and there where crowded, to give those remaining efficient space to develop fully and keep the beds free from weeds, so that the Seakale leaves are not hidden from the light or the soil impoverished by the weeds. If the heads were not cut, flower-stems will have been made, these preventing the crowns developing in a satisfactory manner. However, it is now too late to remedy this evil. The only thing to be done is to cut off the seed-pods, which will relieve the plants of some strain attendant on the production of the seed-pods.—S. P.

—When cutting ceased in spring the old growth should have been trimmed off close to the ground, and the young shoots thinned to one or two to each crown. It is too late to do this now with any prospect of getting strong growth this season.—E. H.

4126.—Tomatoes sporting.—This is a singular term to apply to what is a very common occurrence in the case of Tomato-flowers. The first flower formed on the earliest bunch is invariably malformed, and should always be pinched out. These deformed blooms do not often appear in the succeeding trusses, and if they do the fruit is not so deeply grooved and ugly, as the first one would be if allowed to remain. The second trouble you mention is as common as the first, about which you need not trouble farther than to pinch off the growth as soon as you see it.—J. C. C.

—The central blossom in a cluster is often abnormal in size, and if permitted to remain will produce a rough, ugly fruit. These blossoms should be pinched off. The Old Red often produces blooms of this character. It is not in common for leaves to form at the end of the truss of bloom. The leaves should be removed.—E. H.

4158.—Tomato-leaves injured.—If the plants show signs of pushing into growth again I should let them alone, especially as there is some fruit on them, and this you say is uninjured. If the tops are killed or crippled out them back to sound wood, and take up a strong shoot from each plant. A couple of waterings with a solution of nitrate of soda or sulphate of ammonia, with an interval of a week between, will greatly help the plants to start into growth again. Do not exceed an ounce to the gallon, and syringe with pure water directly afterwards, or the young growth will be scalded.—B. C. R.

—It is a serious misfortune when the leaves of a plant are destroyed in the way indicated, but if the plants are strong and the stems uninjured they will soon break into growth again.—E. H.

4153.—Tomatoes in a greenhouse.—I should fancy the cracking was, to some extent at least, caused by the dry weather, which has a tendency to harden the skins before the fruit has swelled to its full size. Perhaps the plants get rather too much water; if they are planted out in beds a soaking twice or thrice a week would be quite sufficient.—B. C. R.

—The most likely cause of cracking is too much water and not sufficient ventilation. A period of liberal treatment following close upon a time of dryness at the root may cause cracking.—E. H.

4121.—English and foreign Tomatoes.—Tomatoes grown in the open air in a warm and sunny climate possess rather more substance and a somewhat fuller flavour than those of the same kind produced under glass in this country; but then the foreign growers cultivate as a rule

very inferior varieties, though a good deal of improvement has taken place in this respect during the last two or three years. It is this, in conjunction that the fruit has to be gathered while almost green and ripens in transit, that renders the foreign fruit so inferior to English. Most of the Tomatoes grown outside have also a very thick and tough skin, and on the whole it would be hard to beat a good English Tomato, grown under glass in a natural manner—i.e., with plenty of fresh air and not too much feeding with artificial manures.—B. C. R.

—Neither Tomatoes, nor any other kind of fruit from abroad are superior or even equal to English-grown produce when grown under glass by first-rate culture, no matter where tested. Those who think differently have never tested first-rate fruit, such as is commonly produced in English private gardens, where things are done well.—E. H.

4150.—Mushroom bed.—The manure was not in the right condition, or the bed was not spawned at the right moment, or the Mushrooms would not have required eleven or twelve weeks to appear. Although the bed may be kept moist on the top, the fact of the Mushrooms coming up brown and withered points to the fact of the beds being dry inside. Examine the manure in several places 6 inches deep, and if found to be dry well soak it with tepid water, and again cover the bed with litter to prevent evaporation of the moisture.—S. P.

4108.—Herbs for winter.—July and August are the best months for drying Herbs, taking them when they have reached their fullest development; cut them when quite dry, tie in small bunches and hang up in an open shed where the air can circulate freely through the bunches. This is better than drying in the sun, as, drying gradually, they retain their full flavour. When thoroughly dried they may be rubbed or broken up fine, and kept in wide-mouthed bottles till required for use. Cooks often dry Herbs spread out thinly on a shelf in the kitchen, and bottle when thoroughly dry.—E. H.

4126.—Hard water.—Hard water certainly checks the growth of plants, especially where these are growing under the protection of glass, and, therefore, under artificial aid, more particularly subjects that are growing in heat. Soft water is by far the best for any kind of vegetation. It is not possible to grow for more than a short time such plants as Azaleas, Heaths, or Camellias with the aid of hard water only. I have no experience of urtic acid; but common washing soda, used at the rate of $\frac{1}{2}$ lb. to 36 gallons of water, previously dissolving the soda in hot water, softens it if allowed to stand twenty-four hours, and also acts as a stimulant to the plants. Water is easily softened in this way by the aid of two ordinary petroleum-casks, first turning the inside of each to remove the taint of the oil. The sediment which sinks to the bottom ought not to be used, of course. Where a larger quantity is required Anticalcaire, commonly called milk of lime, gives the least trouble in preparation; 1 lb. will be sufficient for 250 gallons of water. All that is required is to dissolve the powder in the bulk of water by stirring it well, when the chalk will be precipitated to the bottom of the tank and the water rendered soft. Even if lime in excess be added to chalk-water, the water becomes turbid, and the carbonate of lime, formerly held in solution, is precipitated, rendering the whole soft. In this way ordinary quick-lime is valuable as a softening agent. Water that is hard is all the better if exposed as much as possible to the full blaze of the sun.—S. P.

—Yes; this is very unsuitable for garden purposes, and if used frequently, for pot plants especially, will soon be found to stop their growth almost entirely. The best way to treat it is to expose it in open shallow tanks to the action of the sun for a day or two at least, and, if possible, immerse still. I should not like to use nitric acid, but a little soda dissolved in the water precipitates a lot of the chalk, and the preparation known as "Anticalcaire" softens it still more effectually.—B. C. R.

4107.—Removing ties and grafting-wax.—The ties may be loosened when the grafts have started into growth. The clay or wax will fall off when the wood begins to swell, but if not it may be removed, as it is not required after the grafts are well established.—E. H.

HOUSE & WINDOW GARDENING.

PERPETUAL-FLOWERING BEGONIAS FOR A ROOM.

THESE Begonias, with fibrous-roots, are perhaps more suitable for room-culture than any other section of that valuable family of plants; for they blossom almost continually, both summer and winter, only requiring to be cut back into shape and repotted to throw out again a mass of lovely flowers, which stand well in a window, and are also valuable for cutting. The well known white variety, *B. semperflorens*, has now been greatly improved, and *B. semperflorens* (Duchess of Edinburgh), lately sent out by Sutton, has flowers of soft pink, twice the size of those of the original variety, borne in as great profusion. *B. s.* (Snowflake), too, is an improvement on the old *semperflorens*, being extremely like the parent-plant, only with much larger blossoms; but *B. semperflorens* *etio-purpurea* is a splendid plant, the foliage being so very well marked with purple and bronze, which harmonise delightfully with its bright-red flowers. *B. s. carinata gigantea* is remarkable for the enormous size of the racemes of bloom, which sometimes reach 1 foot across; and as the flowers are carmine the effect is very handsome. *B. s. John Heal*, also bright-rose colour, has fine flowers, which last a long time on the plant, and do not easily drop, as some Begonia-heads are apt to do. This is one of the best of the improved Perpetual Begonias, all of which have larger flowers than their progenitors. Plants procured now, having been struck from cuttings in early spring, should be placed in 4-inch or 5-inch pots, well drained, using a good compost of leaf-mould and turfy mould, with a little sand, and a sprinkling of soot. They can be grown on in a sunny window, as near the glass as possible, turning them round often, so as to prevent them from growing on one side more than the other. When the pots are full of roots the plants may have a slight shift, when they should begin to bloom. I. L. R.

CARNATIONS FOR A WINDOW.

THESE favourite flowers, which often rank next to the Rose, the queen of flowers, in public estimation, are usually grown, at this time of year, in borders or beds. But there is no reason why those who have no garden, and yet wish for Carnations, should not grow them in pots, for they are easily managed in this way, and even bear transplanting from a border just as they are coming into bloom, without any injury if the operation be carefully performed, so that their thick ball of roots is left intact. Having arranged plenty of drainage and a little rich light compost in a pot which is suited to the size of the plant (it must not be too large), the Carnation, having been thoroughly watered the previous evening, can be raised with a small spade, and placed in the pot, filling in the interstices with the same compost of loam, leaf-mould, soot in small quantities, and enough sand to make the whole light. Room should be left at the top for a thorough supply of water, and the plants should stand in a cool, shady place for a few days. It may then be placed in the window, where it will proceed to open its buds exactly as though it were in the border, filling the room with its delicate fragrance. Cuttings of Carnations taken now will root strongly before the winter, and are easily grown without a garden or greenhouse. They should be inserted singly (after trimming off the lower leaves to the depth of 2 inches), each in a small pot, well drained, full of very sandy soil without any trace of manure. These pots, each containing a cutting, should stand in a cutting-box—i.e., a deal box 10 inches or 12 inches deep, such as can be bought at the grocer's for a few pence—on a layer of fine ashes, which must be constantly kept damp. Cover them with a few pieces of glass, and keep them in the shade out-of-doors (on the leads, or in a back garden), or in a cool room, keeping them close—i.e., without much air—for the first month, after which the glass can be gradually removed, until the little plants are quite hardened off. They may then in September receive a slight shift, giving them still small pots but a rather compact soil. They will then stand safely through the winter in the open air, their pots

being covered with fine ashes. In the case of heavy snow, however, it may be well to give them the shelter of a box turned over them, as though quite hardy, frozen snow often rots their stems and foliage, after crushing them by its weight. They can also be wintered in a room without a fire if more convenient; but they must have an ample supply of light and air daily, as coddling is the one thing they will not stand. Repotted in March, giving them good compost and slightly larger pots, they will flower early if placed in a sunny window with plenty of air; and by means of keeping some of them entirely out-of-doors a succession of delicious blooms can be had throughout the summer. I. L. R.

BEST TABLE PLANTS.

Among the best of table plants are the old White Azalea indica and the variety called Fielder's White, grown in the form of low, loose bushes, as shown in the annexed cut. They look exceedingly well placed in vases, either for general room or dinner-table decoration.

FOLIAGE PLANTS FOR ROOMS.

During the hottest summer months flowering plants are, as a rule, very transient in their beauty, especially when employed for indoor

decorative plants, but they require a warm house when the tubers are started into growth in spring, and a stove temperature to keep the tubers cool during winter, but after they are started into growth in spring they may be gradually inured to a cool temperature, and when properly hardened off are wonderfully effective for decorations of any kind. Crotons in great variety are amongst the most beautiful of all exotic plants, very graceful in growth, richly-coloured foliage, and capable of sustaining a large load of flowers from a small pot; few plants can equal well-grown Crotons. Coleus are especially summer plants, for they delight in heat, and being of very rapid growth they are very much used for decorations, as the brilliance of their leaf-colouring rivals the most showy of flowering plants; they are very readily increased by cuttings. Dracaenas are not only effective, but they withstand the trying ordeal of indoor decoration as well as any class of plants. Some of the very brilliant-coloured leaf Dracaenas require a high temperature, but many of the green and bronze-leaved sorts are quite at home in the greenhouse. They are readily increased by root cuttings, or by pieces of the stems of old plants cut up into lengths, and plunged in a brick bottom-heat. Ferns, both native and exotic, are a host in themselves. Nothing can be more cool and inviting than the verdant

FRUIT.

INSIDE BORDERS FOR VINES.

THERE will always be a difference of opinion as to the superiority of inside borders over those outside, though it would appear that very many gardeners are somewhat shaken in their old prejudices against the former. That outside borders are the safest and best, as far as amateurs and either careless or inexperienced gardeners are concerned, there is no disputing, but that they are to be recommended generally is quite another matter. It is very certain that they are unsuited for the earliest Vines, and equally so that Grapes with their roots in an inside border hang longer than is the case when the roots are wholly or largely outside. I hold that far too much has been made of the Vine's tendency to form roots the most freely and extensively in outside borders, and the originator of the practice of forming both inside and outside borders has much to answer for. It is a poor and also an expensive way out of what to many is a dilemma. Either the roots ought to be rigidly confined to an inside border, or else they ought to be kept outside altogether. Many people have taken a vast amount of pains with the inside border under the impression that they were greatly benefiting the Vines thereby, only to find that the greater part of the active roots is in the outside border. Then, because the discovery is made that the roots have a predilection for the outside, the conclusion was arrived at that it is the best place for them. I repeat was arrived at, the past tense being most applicable in this case for the simple reason that we are becoming more enlightened in the matter. The effects of the very wet summer and autumn of 1891 were too apparent in the case of many Vines with their roots largely or wholly in outside borders, bunches being too few and the quality far from satisfactory. There was also a weakness about the growth, the wood not colouring or ripening at all satisfactorily, all of which, I think, may safely be attributed to the badly-saturated borders. Outside borders are largely at the mercy of all weathers. If we take precautions to ward off excessive rainfall, heavy snows and severe frosts, these very precautionary measures may easily do more harm than good; at any rate, such has been my experience, while if left quite uncovered, saturation at critical periods may work untold ill. In the case of two vineries under my charge the roots are wholly and unavoidably outside, and we have to proceed very cautiously to work to avoid failure. Last season we were under the necessity of giving a second thorough soaking of water, the rainfall having been unprecedentedly low up to midsummer. The very next day thunderstorms were threatened, and although the gardens and country generally wanted rain very badly, to me it was a positive relief that we escaped the storms at that time. Had a soaking rain fallen on our already thoroughly moistened borders, shanking would have commenced in a few hours. I mention this in order to illustrate the difficulties under which those in charge of outside borders labour. In a wet season there was no preventing saturation, and shanking took place in the case of Black Ham-burgh very badly, while the Muscat of Alexandria, Gros Ouillemo, Madresfield Court, and Gros Maroc also behaved rather unsatisfactorily in that respect. Not being obliged to start the Vines very early last year, nothing approaching a failure occurred; but the case was very different in other gardens where Vines in outside borders were started early. According to my experience, any forcing in the case of Vines with their roots, or what are alive of them, in a saturated outside border must be very cautious indeed, or otherwise tendrils and air-roots, rather than bunches, will be the order of the day. What may be considered the strongest argument against inside borders is the fact that they must be given abundances of water, or far more than is ever considered necessary for those outside. That they do require to be kept properly moistened there is no denying, but that they require such immense quantities of water as some writers advise should be applied I unhesitatingly deny. No hard and fast line can be laid down as to the quantity an inside border should require, so much depending upon the quality of

White Azalea indica as a table plant.

decorations; in fact, many of the most beautiful of the summer-flowering plants drop the blooms to such an extent that they are practically useless for taking into the dwelling-house; and foliage plants, either green or variegated, form the staple of decorations. The following are sure to give satisfaction—viz,

ARALIA SIEBOLDI is probably one of the very best plants for all-the-year-round decorations, as it withstands heat or cold that would prove fatal to many more expensive, but certainly not more useful or beautiful, plants, and quite a large plant can be grown in a comparatively small pot. This is very readily increased by seeds or cuttings, but I prefer seedlings. Aralia Sieboldi variegata is the exact counterpart of the former, only that the foliage is very beautifully variegated. Aspidistra lurida variegata (Parfour Palm) is another excellent plant—in fact, beautiful specimens may be found grown entirely in dwelling rooms. It requires an intermediate temperature, and is increased by division. Araucaria excelsa (Norfolk Island Pine) is one of the most symmetrical plants grown naturally that can be imagined, the tiers of branches spreading out like the ribs of an umbrella, and of the most lovely feathery green. It may be utilised for greenhouse or conservatory when not employed for indoor decoration. Caladium, in great variety, make beautiful de-

green of Ferns, and amongst them can be found varieties suited to the smallest vases for ladies' dressing-room tables or for the massive jars that are used in entrance halls; they thrive in the subdued light of dwelling-rooms. Ficus elastica (the India-rubber-plant), with its thick, leathery foliage, is exceptionally well suited for decorative purposes. Young plants are beautiful for vases, a sponging to remove the dust occasionally keeping them healthy for a long period. New Zealand Flax is a fine, stately plant, with sword-like leaves, very effective for large vases. Its variegated form is exceptionally bright. Palms of many kinds suitable for cold, intermediate, or stove temperature, are the most stately of foliage plants, and being vigorous rooting subjects are able to live where more tender plants succumb. Thousands of Latanias, Seafortias, Kentias, and other popular Palms are sold every year by some of the large nurserymen. JAMES GROOM, Gosport.

4161.—Plants for Sheffield.—You can obtain plants of several varieties of Thrift from almost any good nurseryman. Give the plants poor sandy soil, and then they will not grow so strong.—E. C. R.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of any rare flowers and good fruits and vegetables for drawing. The drawings so made will be returned in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

the soil need and the extent of the Vine's root-action, but there ought to be no mistake about when water should be applied. Never ensue should the soil become sufficiently dry to crumble freely in the land when tested. Once let the border become so dry as that, and re-moistening may easily exhaust the so many thousand gellons we sometimes hear of being needed at one watering. Dryness ought always to be anticipated, and not waited for, as very often happens. Why should a border be treated differently to soil enclosed in a pot? In the latter instance if we wait till it gets thoroughly dry or sufficiently so to shrink considerably, several lots of water have to be given and very much wasted before it can be properly re-moistened. It is exactly the same with inside borders. Having to use sufficient water to flush the drains underneath is simply so much labour and fertility wasted, the water carrying away much that ought to remain in a border. My contention is that if the water is timely applied a very little will go a long way. All have not a tank of soft water conveniently near, and lately water of any kind has been very scarce in some gardens hereabouts, but surely enough is forthcoming in most cases to water inside Vine borders. Our soft-water tanks were soon exhausted this season, and cold spring or well water I strongly object to for watering. My way out of the difficulty has been to fill a galvanized iron tank, holding about 40 gallons, and this being set where it got the benefit of the heat from two hot-water pipes was well warmed in a few hours, while the addition of a 10-inch potful of soot, worked up into a paste, rendered it soft and otherwise beneficial to the Vines. Four of these tanks thus prepared are found ample for a Vine border 34 foot by 14 feet. This border has been made for about nine years, and wholly supports twelve strong Vines. Undoubtedly, if the inside borders are neglected, that is to say, are very seldom loosened on the surface or renewed, top dressed or mulched in any way, water also being too seldom applied, the Vines would do better with their roots outside. It must also be conceded that it is no easy matter to confine the roots wholly to an inside border, no matter how well the latter is treated, but, all the same, I would strongly recommend all intending planters to make the attempt. All the water of the roof of a vinery ought also to be stored in tanks, these being necessarily or preferably outside, as they would take up too much room in all but the largest houses, handy pumps and galvanized iron tanks for warming the water being fixed inside.

W.

PEACH-TREES AFTER FORCING.

This is the time when the trees are apt to get neglected, either from want of water at the roots or through being overrun with insects—two evils the grower must guard against. Trees which are neglected at this time will never succeed well, for if insects should gain the upper hand the premature loss of foliage will be the result, and will surely lead to bud-dropping later on. There cannot be any question as to the advisability of exposing the trees as much as possible, but I believe that the wood of these early trees can be overripened. The buds become, as it were, too plump, and although this may be looked upon by many people as a criterion of the trees being in a very satisfactory condition, I do not think so. If the wood be fairly well ripened, the longer the leaves are retained in season the better. Trees on open wells rarely lose their leaves very early, as generally it is the latter part of November, or even into December before they all part readily; yet this does not prevent the trees from forming fruit-buds and flowering most profusely. In many of the more modern structures it is quite evident that insufficient ventilation is provided. The result of this is that the structures remain very hot and dry throughout warm days. Although it is only on rare occasions nowadays that the roof lights of early Peach-houses can be removed bodily throughout the summer months, the least which can be done is to let down the roof lights as far as they will go, and also open the front ventilators to the same extent. If the borders be kept well moistened, and the foliage also well syringed two or three times a week, the leaves will remain fresh to the last. When leaves commence to fall early it is a sure sign

that something is wrong, either through drought or insect agency. Red-spider is one of the worst insects to contend against, this very quickly sucking the life's blood out of the leaves, with the result of their dropping very prematurely. With any insects present, care must be taken in the use of insecticides, or the remedy will prove as bad as the evil, the leaves dropping very quickly. If red spider should be present, the safest remedy is to work a double handful of sulphur into a 3-gallon can of oof water. By working the sulphur through a piece of muslin it mixes readily with the water, and may be evenly distributed over the foliage through a syringe. This should be left on for a few days, and the trees heavily syringed afterwards. Tobacco-water is a good remedy for thrips, but I am also very partial to a decoction of Quassia chips and soft soap. A pound of each boiled for ten minutes, and afterwards strained, will be sufficient to make a dozen or fourteen gallons. I cannot speak so favourably of the Quassia extract, and which I was led to try after reading glowing reports in its favour. This season I have given it a fair trial according to directions for a slight attack of fly. It killed the fly certainly, but it caused many leaves to fall from both a Pine-apple and Victoria Nectarine. Peach and Nectarine leaves are certainly very sensitive. The old remedies of Tobacco-water, Gishrat compound, and the decoction of Quassia chips and soft-soap are hard to beat. Where scale is present little can be done until the leaves are on the point of falling, for any insecticide applied strong enough would cause more leaves to fall prematurely than the graver bargained for, but the remedies for other insects would check its progress until more vigorous measures could be adapted. With these early trees the cutting out of the old fruiting wood or such as is not required for extension should be deferred until later on in the season, as, unlike the later trees, the extra wood would be of more benefit than otherwise. Also pay particular attention to the watering, not surface driplets, but thorough soakings, applying them through a mulch of stable litter, this latter being of more benefit than layers of cow manure and such like, these closing up the surface and so preventing that aeration so essential for the well-being of the trees. If the soil is known to be rather exhausted or of a sandy description, then frequent applications of clarified liquid would be of benefit, but any indiscriminate use of liquid-manure is positively injurious, it having the effect of souring the soil. Rain or pond water is the best, sufficient being given to thoroughly moisten the whole border. By attending to the above rules in the cultivation of Peaches under glass the trees will remain healthy and retain their leaves to the last. Instead of the early dropping of the leaves being a criterion that it is through the wood being in a satisfactory condition, it is just the reverse.

H.

4175.—**A lean to vinery.**—This is a case of scorching of the leaves by the sun, caused principally through the growth being too near the glass. A distance of 9 inches between the wires and the glass is not enough; it should be 14 inches. Lower the Vine-rods temporarily until the autumn, when you can have them pruned and the wires brought further from the glass. Your management in other respects is all that can be desired, and your enquiry clear and to the point.—J. C. C.

— Except that the young leaves were close against the glass and were wet at the time, the sun was shining upon them before air was admitted. I should not say the nearness to the glass of the wires is the absolute cause of the mischief complained of. Undoubtedly, though 9 inches does not afford enough space for the foliage, nothing less than 17 inches is sufficient to do justice to the Vines, especially if the growth is strong. I should be inclined to think the roots had become dry previous to watering them, or that the temperature inside has become too much heated before admitting air. Either of these causes would account for the injury to the leaves. It is surprising how quickly the soil becomes dry in a new border, especially if it is raised above the natural ground level, and drained also.—S. P.

4176.—**Treatment of Raspberries.**—Do not transplant any of the young canes yet.

the weather is too hot and dry; October is the best month. You must cut all the old canes right away as soon as they have done fruiting, and thin the young ones (of this year) out to not more than five to each root, or as many as can comfortably be found room for; this may be done now, leaving the strongest only. It is a great mistake to crowd the canes too much; unless well ripened they will not fruit well, nor will the berries ripen as they should.—B. C. R.

4157.—**Treatment of Vines.**—Heat and moisture in moderation are essential to the well-being of Vines in a season like the present. But this treatment may easily be carried to excess, especially when mildew is present. A drier, more breezing condition of the atmosphere will be better if the mildew is to be cleared out. At the same time see that the roots are not too dry. Dryness at the root is often a cause of mildew.—E. H.

4147.—**Treatment of Melons.**—Instead of pinching in the leader it ought to be allowed to grow uninterrupted until the top of the trellis is reached, or, say, for about 5 feet. Side shoots will push from the joints below, quite sufficient to give a full crop of fruit. If they do not promise to grow then pinch the leader for the purpose of forcing out these side growths. The short side shoots are those which show fruit directly they have made two leaves. The female blossom is easily detected, having a small fruit immediately below the blossom. The males are simply flowers, only they are generally borne on the main stem. It is absolutely necessary to fertilise them to make sure of a crop. It is a simple matter: About the middle of the day, when the flowers are dry, pick off a male bloom from the same plant that the seed of the future fruit may be the same, so as to avoid intercrossing of varieties. Remove the petals, exposing the pistil with the pollen attached, place the point of the pistil amongst the stamens of the female blossom, fertilising them with the pollen. In a day or two, if the impregnation is satisfactory, the fruit will commence to swell. It is wise to fertilise all the blooms on one plant at the same time, a better general swelling of the crop is obtained. Three full-sized fruit of the large-growing kinds are sufficient to have them of the finest quality. When the blossoms commence to unfold syringing the foliage should be discontinued for a few days until a perfect set is obtained, when it should be resumed twice daily. Melons require much moisture at the roots when growing freely, and the drainage is in perfect condition as it should be; but care should be exercised when pouring the water on the soil not to wet the stem of the plant no more than is necessary, as canker is sometimes caused in consequence, and this is a serious matter to contend with when the plants are swelling a full crop of fruit. Liquid-manure given alternately with clear water when the fruit is swelling freely is a great assistance in producing exhibition fruit. As the fruit exhibits signs of colouring, and approaches the ripening stage, more air is needed and less moisture, both atmospherically and at the roots. The flavour is improved in consequence; but it is a mistake to allow the soil to become quite dry before the fruit is really ripe.—S. P.

4171.—**Fruit-trees, &c.**—The loss of crop has doubtless been caused by spring frosts. This might have been obviated by protection in spring. I dislike narrow houses for Peaches. I have a house with a 12-foot raft, and I never enter the house without wishing the trees had more room. But in the case under consideration it would doubtless pay to cover the wall with glass in some cheap way, making special provision for plenty of ventilation. If possible, it should reach the whole range, though half might have more pipes than the other half; and I should plant the earliest kinds by themselves. Dymond is a good Peach to grow for sale; it is a splendid colour and bears well. Hale's Early is a fortnight earlier. Rivers' Early York is still earlier, but has not taste enough; and Waterloo and Alexander are too uncertain in setting to be recommended on a small, narrow house. Do not neglect Nectarines. I find good Nectarines pay better than Peaches. But Peaches are a rather uncertain source of profit; they are very profitable if you have made a good price one week, and the next be disappointed. Still, on the whole, good fruit does not market in good condition does not fairly well. The competition is

UNIVERSITY OF URBANA-CHAMPAIGN

been in the work now, and every year the prices run lower. There are exceptional times, such as the royal marriage week, for instance, when the leeway can be made up, but, on the whole, this has not been a good season for selling Peaches.—E. H.

— You are not wrong in your ideas, only in some of the details. In the first place, a simple wall plate put on the top of the wall will bring the top of the trees alarmingly near the glass—too near, in fact, as you cannot afford to lose any space on the surface of a wall only 8 feet high. You do not say how you intend to ventilate the house. For a cool house the simplest way of ventilation is that of the Paxtonian system, which has narrow lights running up the roof at equal distances apart, but I should prefer to put a ventilator 1 foot in depth on the top of the wall, using small lights and hanging them on a pivot. This will increase the length of rafter, but it will bring the top of the wall a better distance away from the glass, which is necessary for the good of the trees. A wall 1 foot above ground, and a ventilator the same depth the whole length on the top of the wall along the front, is what you want. The roof I would make up with lights

to attempt to renovate them in this way. If they have been planted more than fifteen years you had better replace them with young ones. If you do the lifting in the autumn shade the roof of the house and keep it close, and syringe the Vines three times a day for a month.—J. C. C.

— The shanking of Grapes in the manner described may arise from more than one cause, and any advice given now will probably be too late to be of much use this season. The Vines lack nourishment, but this may arise through the roots being in a bad state from working in an unamiable soil, or (see this season has been exceptionally dry) the border may be too dry for healthy root action. In the latter case, a good soak with liquid manure, or a dressing of dissolved bones and nitrate of soda, watered in, will be beneficial, and will give increased size to the berries which are not shanked. If the fault arises from the roots being in a cold, deep, undrained border, the only remedy will be root-lifting, and a new border.—E. H.

4127.—Vines in pots.—If Vines which have been kept in pots seven years have never fruited there must be something very wrong in the culture. To obtain fruit from a Vine in a

Persia. I have seen that has on a few fruits, colour purple; it makes a splendid object when in flower.—E. J. Vokes, Kingsworthy.

4151.—Sorts of Apples for grafting.— You ask a very interesting question with regard to the Blenheim Orange Apple, and I am glad to be able to answer you from practical experience of its behavior when grafted on other trees. Your own limited experience points to the same results as mine, that grafted trees—if not too old when operated upon—come into bearing much better than young ones. Two years ago I saw picked 3 bushels of Blenheims from a tree that had only been grafted two years previously. Of course, several seasons were put on—I think fourteen was the number. You need not hesitate to use all the sorts you mention; but I advise that Blenheim Orange predominate if the trees to be grafted are standards. For other forms of trees the others you mention are the best.—J. C. C.

FERNS.

HARE'S-FOOT FERNS (DAVALLIAS).

DAVALLIAS form beautiful ornaments when grown on a Tree-Fern stump, as shown in the accompanying engraving. Indeed, I look upon this as the natural manner of growing them, and when thus treated Davallias make an interesting display in the Fern-house, and relieve it of formality. The plants require ordinary care when treated in this manner, and little else but an abundant supply of water is necessary, and some peat-firn and Sphagnum Moss fastened in the arms or branches of the stem. A pretty example treated in this manner I saw recently in the gardens of Heaton House, Cheekum, and the one here depicted is a charming group. The kind which may be treated in this manner require to be somewhat carefully selected, for many of the species which appear to be small enough to be treated will make enormous fronds if encouraged, and, therefore, although simply magnificent when accommodated upon tall and large stems, they would be considerably out of place planted upon such an example as is here illustrated. The kinds most suitable for the Tree-Fern stumps may be briefly enumerated.

D. PENTAPHYLLA.—A distinct species with fronds some 9 inches or 12 inches long, and, as its name implies, with two pairs of pinnae and a central one, making five. These are broad and bright shining green in colour, paler beneath, the fertile frond slightly contracted. When first placed in the position here indicated, it may appear to be somewhat thin and sparce; but as it grows it will become a fine and telling object in the fernery.

D. DISSECTA is an extremely handsome plant for this purpose, and a very free grower. A form of this, D. DECORA, is also exceptionally beautiful; its fronds are broader and shorter, thus giving them a more distinctly triangular appearance. The typical plant has long creeping rhizomes, which are clothed with large drab-coloured scales, and its fronds are from 1 foot to 2 feet long, and some 8 inches or 9 inches broad.

D. BULLATA.—This in the plant illustrated, and is smaller than the preceding. It is at once distinct, as it casts all its fronds in winter. They are about 1 foot long when the plant is strong and vigorous, but more frequently they are some 8 inches or 9 inches in length, bright shining green in colour, the rhizomes being clothed with reddish-brown scales.

D. CANARIENSIS is also well adapted for this style of culture, but it requires more care to establish it, as it is slower in growth, and the rhizomes do not so readily attach themselves. Moreover, it is a plant which thrives in a cool-house, the other kinds requiring stove temperature. In this plant the fronds are heavy and massive, triangular in outline, and deep-green.

The above named may be accepted as amongst the best of the small-growing kinds, although there are several species of an allied genus (Humata), which are equally adapted for this kind of culture. The large-growing kinds I will reserve for another occasion. J. J.

Hare's-foot Fern (Davallia) growing on a Tree-Fern stump.

4 feet wide. The light will come a trifle dearer than a fixed roof, but lights are always saleable if at any time the house is not wanted, while a fixed roof is not worth much. The pitch of the house will be right enough for Peaches. If you intend to market your fruit, I do not think under the circumstances it will pay to divide and heat the house, seeing how many valuable early sorts of Peaches there are now. Good fruit of Amaden June and Alexander generally realise a good price. I would not plant any more mid-season varieties, but fill the remaining space with such late sorts as See Eagin and Barrington. Nectarines do not realise so much money as Peaches. The best sorts are Lord Napier and Victorin. If you cannot get the house it will afford plenty of work for the remaining two days your man now has on his hands.—J. C. C.

4117.—Grapes dropping off.—This is a bad case of shanking for which there is no remedy other than lifting the roots and replanting them in a new made border. In such a case as yours I should advise that the lifting be done from the beginning to the middle of October, the Grapes, of course, being (B.C.) viciously removed from the Vines. I am, of course, assuming that the Vines are not too old

pot is quite a simple matter if the plant is well grown in a light position, so that the cane is well grown and ripened. There are certain kinds which fruit better than others. Hamburghs, Sweetwater, Alicante, and Frontignans may be fruited well in pots; but the plants must be well grown, and all the force and strength of the plant directed into a single stem or cane; and it is important that the cane be trained near the glass. One finds it difficult to understand how anyone with even only a rudimentary knowledge of gardening under glass could fail to produce Grapes on pot-Vines for seven years.—E. H.

4125.—Prunus Pissardi.—I have seen this beautiful tree fruit remarkably well. It was about three years ago, as far as I can remember. I am not aware whether the fruit is pleasant to the taste or useful, but it looks as if it would make a good preserve.—C. T.

— This plant ought to bear as freely as our common Plum; but being a native of Persia, the blooms appear so early that most of them are cut off by frosts, being so tender a plant. It would be easy to eat the fruit, but it is of poor quality. The tree is grown mostly for its coloured foliage, much like the leaves of our coloured-leaved Beech. It was named after the artist, Pissard, gardener to the Shah of Persia, and only recently imported to England from

Original from
CITY OF ILLINOIS AT
Hardy Ferns—in many gardens bare
UNION SQUARE CHICAGO
it is impossible to get plants

to grow—at least, not those bearing flowers, and it is in such positions that good use should be made of the many varieties of hardy Ferns. This note is prompted by seeing a very narrow shady border in a suburban garden a perfect sea of foliage from the handsome fronds springing from large clumps of male and hardy Ferns. The only preparation necessary is to first make a good soil for the roots, and, when necessary during the summer months, give a thorough watering, which will promote vigour and fine development of the fronds. It is surprising how well apparently hopeless corners, as regards plant culture, may be made to look when the proper things are selected.—V. C.

4106.—Ferns for show.—There is a large number of Ferns available for exhibition, and you cannot do better than make your selection from the following: *Adiantum cuneatum*, *A. Farleyense*, *Microlepia hirta cristata*, *Davallia Mooreana*, the beautiful *Nephrolepis devalliioides* ferns, the *Gleichenias*, which are often seen at the larger exhibitions in winning collections, and the well-known *Cyathea dealbata*. Several others have recently appeared in GARDENING upon Ferns for an exhibition.—C. T.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the locality in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4183.—Pot-root Dahlias.—Will someone kindly tell me how to propagate pot-root Dahlias?—J. E.

4184.—Shamrock.—Will someone kindly tell me the treatment of a pot of Shamrock, and how long does it last?—F. BROOKER.

4185.—Cracks and dark spots on Tomatoes before ripe.—I shall be glad to know cause of the above.—H. G.

4186.—Budding Briars.—I potted some Briars last October. Would it be to bud them this August with H. P. Rose-buds?—F. G., Devon.

4187.—Bed of Ornamental Thistles.—Which has the best of ornamental Thistles next year. Should like names of good sorts, and when they should be planted?—C. A. B.

4188.—Fear for south-east wall.—Will someone please tell me what kind of tree to grow on a south-east wall in a rather shady position; also what time to plant?—New Subscriber.

4189.—Propagating Birch, &c.—Will someone please state a good method of propagating Birch, Hazel, and such like trees? Are they usually raised from seed or cuttings?—A. M.

4190.—Camellia cuttings.—I have a Camellia cuttings, struck in water, roots a quarter of an inch long. Will someone please tell me how it should now be treated? I am told Camellia cuttings so struck always die.—M. F.

4191.—Unhealthy Marrows.—In the last few days the leaves of one of my Marrow plants have become covered all over with yellow spots, and warped. Will someone kindly tell me the cause of this, and how to cure it?—AMATEUR.

4192.—Sensitive-plant.—May I ask someone to tell me to management of a Sensitive-plant? I bought one about three months ago, but long will it last, what treatment in winter, and what heat do they require to keep them?—F. BROOKER.

4193.—Roses in a window.—I have two monthly Roses and one Hybrid Perpetual in a window facing the west. They are now in flower. Would someone be so kind as to inform me the best way of keeping them during the winter?—JOSEPH MARTIN.

4194.—Roses for India.—What is the best way of taking Rose-plants to India—by buds, or cuttings, or how otherwise? And how should they be packed; and what Roses best suit a tropical climate—say Bombay and the neighbourhood?—Mrs. E. STORFORD.

4195.—Sowing down a lawn.—The lawn in front of my house was very uneven in surface. I had it dug up the beginning of last winter and sown with fine grass seed in spring, but owing to the drought it has never thriven. Should I sow it again now or wait till next spring?—E. C.

4196.—Onting Laurustinus.—I shall be much obliged if anyone will kindly tell me when I should have Laurustinus cut so as not to lose the bloom? I have a hedge of them which has now grown far too high. My garden is at the seaside, south coast. (Sussex).—G. I. G.

4197.—Pots becoming green.—Will someone kindly inform me the probable cause of pots with plants in being so green on the outside? Is it with too much water, stiff soil, or the hard kilned pots, as they are hard-burnt? Will it injure the plants if not washed off?—YARD.

4198.—Plants for windows.—I have five windows in town, three facing the north, two facing west, and one north-west. In one of the west windows I have three hardy Rose-plants. Would someone please inform me of the best plants for the others, and their management?—JOSEPH MARTIN.

4199.—Treatment of bulbs.—What bulbs do best undisturbed in the ground? What bulbs may be put in in autumn and lifted in spring to make way for bedding plants, and may these same bulbs be used year after year? Do they deteriorate or increase? How are they best stored?—AN AMATEUR.

4200.—Old Vines.—I have two rather old Vines, but still very strong and healthy. There has been a splendid show of Grapes this year. They have been carefully thinned and cared for. Quite lately a blight has appeared upon many of the bunches. Will someone please tell me what has probably gone wrong, and if I can remedy it?—WALLACE.

4201.—Forcing Rhubarb.—Would anyone be so kind as to give me information how to force Rhubarb for market purposes? Were it forced under the stage of a greenhouse, and how much soil and manure are used, and in it placed firmly among it? Are this year's roots lifted out of the ground and potted?—HUGH CRANFORD, Easter-Nill, Tollerous.

4202.—Destroying ants.—Will someone kindly advise me how to get rid of an ant's nest? They are in a border by the house, and have been established there for many years, and seem to come from the foundation of the house. I have poured tar on them, and also several times boiling water, but cannot get rid of them. I should feel very obliged if someone could give me a remedy?—ANNIE.

4203.—Potted ferns crassipes.—A friend of mine purchased a plant named Potted fern crassipes, an aquatic plant from North America. It has grown so rapidly as to necessitate removal to larger quarters several times, but cannot be induced to flower, although the catalogue account says that it would blossom in a short time. Common name Water Hyacinth. Should be pleased with a few hints to induce it to bloom?—W. J. POLKAK.

4204.—Treatment of Carnations.—My Carnation bed is doing splendidly, but it contains mostly Old Ormeau Carnations. By which means should I obtain most flowers next year—by layering them, and throwing away the parent plant, or by leaving the old plants as they are; or combining both by layering the shoots around the old stem and leaving it? I have one plant only of Greadin, with but few offshoots; how best to increase the stock?—VIVIAN.

4205.—Treatment of a Passion-flower.—Will "J. C. C." or some other kind reader be good enough to give me some information as to the following? I planted a small Passion-plant last October—was also about 2 inches high—it remained quite green all the winter, but in the spring the top died away, and a young shoot came out from the bottom, and has grown to a height of 8 feet. I want to move it to a more sheltered situation. Would it be better to move it in the autumn or wait until spring, and be sure to prepare the ground?—NEW SUBSCRIBER.

4206.—Grubs in a garden.—I am troubled by grubs eating of my Onions and Carrots, they eat them through about 4-inch under ground, never touching the tops. Upon examination I find close by dark skinned insects, exactly like caterpillars, and rather large. Will someone kindly inform me how to get rid of them, and how when sowing more Onions seed I should so prepare the ground as to stop their depredations? Will suit to the ground do any good, or slaked lime?—ANNIE.

4207.—A remedy wanted.—Will someone kindly give me a cure or tell me the cause of what is commonly called "hives"? I think it must be the bite of some insect which only infrequently finds garden, and is first noticed about June. It irritates the skin and leaves a large blister. None of my family have seen the insect, which must be because it has no roots. Turn it out and see for yourself. Put it in some sand and old mortar-rubbish, and keep it warm in the sun, but do not give it much water—in fact, none at all, until you see it begin to root.—J. J.

4208.—Treatment of Roses, &c.—Last season was my first one with Roses. District, Shooter's Hill. Soil, clay, well prepared. Countess of Rosebery flowered well last year, and true to colour; this year it is the same colour as Dugny Jamin. Why is this? Maurice Bernardin does no good; grows well, but buds do not open properly. Very small, although they are all sufferers, being covered with the blisters or rash, some of them that came from a distance being attacked after one day's stay. An answer will greatly oblige.—L. McE.

4209.—Unhealthy Cucumbers.—Would someone kindly tell me what has effected my Cucumber-plants? A short time ago I made up a mound on the top of the slates of propagating pits in a greenhouse, and planted the said plants, and they grew on very well till last week, when I noticed one of the plants began to die. Thinking it was dry, I gave it some water, but it never held up again, so I cut it down, and I found it was rotten at the collar. I should be glad if anyone could tell me the cause of this going like it? I have some more like it in fruit, and I thought not like to lose them.—A CONSTANT READER.

4210.—Heating a small greenhouse.—I desire to heat my small lean-to greenhouse, 18 feet long, 5 feet wide, 7 feet at back, 5 feet 6 inches at front, facing south, by means of 22 feet of 4-inch of pipe. A wash-house, in which I propose to place the boiler, runs at right angles, and adjoins the end of greenhouse, with its floor level 5 feet below floor-level of greenhouse. I possess a boiler 10 inches by 6 inches, 4 turns 1-inch bore, which I propose setting in a deep brick furnace. My idea is to

build the furnace on floor, starting with a large fire-brick or hurr, and work on the slow combustion principle with-out fire-bars. Will "B. C. E." be good enough to inform me what distance he would allow between bottom of coil and surface of bars? What size furnace he would use, and whether he would construct the same in any special manner?—G. H. W., West Brighton.

4211.—Ground for a Rose garden.—Will anyone tell me how I should set about preparing ground for a Rose garden? The soil where I propose to plant the Roses was originally poor but is now deep and fertile; it is, however, hardly a Rose soil there being very little clay in its composition, for which reason also fruit-trees soon become exhausted and unhealthy if planted there. The ground is exposed to the sun, and floo a sloping position which makes it somewhat dry and more suitable for Tea Roses than Hybrid Perpetuals. I propose to lay it out in large beds and rows of standards, as I want to grow all sorts of Roses there. I have great hopes of success, as in the garden below the slope Roses grow well.—K.

4212.—Artificial manure for a garden.—Will someone recommend any artificial manure for large kitchen garden under following circumstances?—Garden cropped season of 1893 with Potatoes and other roots; season of 1892 with Potatoes and green crops that stand winter; season of 1891 not cropped at all; season of 1890 with usual garden crops. The garden has a large number of fruit-trees (of various standards), which have borne heavily each year. Soil, a heavy loam. No manure has been used since the autumn of 1889 or the spring of 1890. I propose to apply the artificial manure recommended when the Potatoes and other roots are lifted before planting greenstuff. Please state how to apply the manure, and quantity per square yard (super)?—EMMA OZBE.

4213.—Extirpating Horse-radish.—I have ten large my grounds an old brick kiln in which for many years I have been allowed to grow my brasses. In autumn last I had it trampled very carefully, but with a dense clay soil the men unvoluntarily left many broken pieces in the soil, which are now developing in small leaves as they spring up. I am having the same pulled up with as much depth of growth as possible. Will this course with perseverance eradicate it, or is there any other known plan to destroy it? Perhaps someone will give me some information as to the best mode of planting a tree of some kind in the centre of a square patch at the proper time for so doing; I also thought of a Rose-tree or two for this patch. I forgot to mention that the ground is rather "clayey." How should I treat it? I planted a Clematis Jackman, I believe, under the kitchen window, facing east; it gets a lot of sun. It thrived well for a week or two, now the leaves seem to droop; the soil is fairly good black soil. Will you say I do?—YVONNE.

4214.—Management of a garden, &c.—I have two pieces of ground (ordinary small back garden size), one piece runs by a wall and faces the north, the second piece is a square patch and faces the south-east. The latter gets a lot of sun, the former piece is shaded by the wall. Can I plant anything now—i.e. what would be suitable and look nice? I should like to plant a tree of some kind in the centre of a square patch at the proper time for so doing; I also thought of a Rose-tree or two for this patch. I forgot to mention that the ground is rather "clayey." How should I treat it? I planted a Clematis Jackman, I believe, under the kitchen window, facing east; it gets a lot of sun. It thrived well for a week or two, now the leaves seem to droop; the soil is fairly good black soil. Will you say I do?—YVONNE.

4215.—Treatment of a Pear tree.—In GARDENING, June 18, I have a question is asked, query 4387, treatment of a Pear-tree, potted six years ago, the leaves in the following week's issue were rather short and concave, but not so full as I could wish. I have a Jargonelle Pear-tree, planted some eight or nine years ago, and as a preventive a stone was placed under it to avoid the tap-root, if possible, and about two years ago a trench was dug round it about twenty inches from the stem, to cut off the roots, but this had no effect. There is still the same over-abundant wood-growth, but no fruit this year, although there was a little blossom, and the most fruit of it in one season has been no more than a dozen. Will someone please to state what is the best treatment for it, and when the long shoots should be cut off?—M. M.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4216.—Ononis (J. M. M.).—I cannot give even a green at the species you have sketched. I am under the impression, however, that the plant is still the cutting which you got it at first, and the cause of its falling away is because it has no roots. Turn it out and see for yourself. Put it in some sand and old mortar-rubbish, and keep it warm in the sun, but do not give it much water—in fact, none at all, until you see it begin to root.—J. J.

4217.—Zygopetalum Clayi (J. B.).—You send a flower of this variety complaining that I did not mention it when speaking of this family a short time ago. Well, it is a hybrid, and these I did not include, and I thought that the Editor would be able to find out the variety, but the variety is about the finest colour form I have ever seen, the sepals and petals being whiter of a rich purple, narrowly bordered with green, the lip of a rich and bright violet-purple. It is one of the best hybrids of this family yet raised, which it was by Colonel Clay, at Birkenhead, between Z. orifolium and Z. maxillare, but it varies very considerably in the depth and intensity of its colouring. Yours is a very superb form.—M. B.

4218.—Odontoglossum (Judy).—The flower is Odontoglossum Halli. I should work a little good possibility into the Spheerium form. The opposite is that which I am told is an excellent thing for them. Indeed, the Belgians appear to be working wonders with this material, but you should not disturb your plants if growing, but report them in the autumn, and they will go on and root and get grow before the hot weather sets in another year. You shall have the colours before they flower, but just now I am very much pushed with queries. They should stand to be about 2 inches in diameter, shade, and have an abundance of air, with a moist atmosphere. I am not in any way alarmed at your asking questions.—H. B. BLOOM.

4219.—Orchid house (John Allen).—I am glad to hear you have a house now up for your Orchids, and I am glad to find you have increased the stock of plants to such an extent, and you have done well in restricting yourself

to the cool kinds. I think, however, you are treading upon stinkish ground when you include *Cymbidium lowianum* and *Odontoglossum vexillarium*, for both like a little more warmth than they can get in a cool-house, but at the present time you would be hot enough. The house should have free air and a cool moist atmosphere, or you will be very apt to get the shriveled up last-named plants. The *Dendrobium Jamesianum* will thrive with *Odontoglossum*, for although of Indian origin, it comes from a cool part of Burmah, and I saw it doing better than I had previously seen it last season in Messrs. Low's nursery, in a house without any fire-heat at all. At this season you should certainly have your bottom ventilators open, and, owing to frosty weather, in the winter also.—M. B.

NAMES OF PLANTS AND FRUITS.
 *Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.
 Names of plants.—M. H. Small.—*Onoclea aurata*.—J. P. Jolly.—*Athyrium Filix-foemina* *Filix-femina* *orientata*.—P. B.—1, *Adiantum formosum*; 2, *Woodwardia radicans*.—Anglice.—*Asplenium Adiantum-nigrum*.—Charles Green.—1, *Lycoctia aromatica*; 2, *Aërides liliatum*; 3, *Vanda tricolor*.—J. Greening.—1, *Gypsophila paniculata*; 2, *Silene maritima* *pleens*; 3, *A. Gallardii*.—W. O.—We regret we cannot name the plants sent; specimens insufficient, and crushed in the post. If possible, send when in flower.—H. Fry.—We cannot name seedling *Carnations*. You can give them any names you like.—F. B.—The *Orchid*-flowers sent were quite rotten from having been packed in wet moss, so it is impossible to name them accurately.—Seaside.—1, Flowers are fallen off, but looks like a *Gedalia*; 2, A *Fianella Lily* (*Funkia subcordata*); 3, A *Larkspur* apparently, but bad specimen; 4, Dried up; 5, Apparently a piece of *Southernwood*; 6, *Santalum incense*.—J. W.—We cannot name from such a specimen.—W. J. T.—Not *Orache*, but we should like to see a fresher specimen.—H. W.—*Campanula germanica*; can be grown from seed.—Canon.—*Viola alba*.—J. S. B.—*Gypsophila paniculata*.—Miss Greenly.—*Lilium pardalinum*.—N. Devon.—Mountain *Osageod* (*Gnaphalium glaucum*). You can name it if you like. We know, except by pulling up every root.—Yorkshire.—1, *Oppopogon Jaburan variegatum*; 2, *Cyperus alternifolius*.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Miss Wall.—Apply to Messrs. Geo. Bunyard & Son, Maidstone, Kent.—P. F. Hunter.—The *Chrysanthemum* leaves are attacked by the grub of the *Merguicula Daley* Fly upon which there have been many notes in GARDENING. The only remedy is to pluck the leaves and so destroy the grub.—L. M.—The Vine is evidently badly attacked by red-spider. Sponge the leaves.—T. B.—The *Tomato*, of course, a fruit, but it is usually shown with vegetables.—Colonel Thornton.—The trees are attacked by the Pear slug. Dust over with slaked lime, and in a few days syringe this off again, and then repeat the application.—E. C.—Apply to Messrs. Barr & Sordani, King-street, Covent-garden, London, W.C.—R. C. Thompson.—The Grapes are scalded from want of early ventilation.—Amateur.—Apply to Mr. George Monro, Salesman, Corvee-gardee Market, London, W.C.

POULTRY & RABBITS.

REARING TURKEYS.

For some reason or other, late-hatched birds do not, as a rule, do well. This is especially the case where the later birds are reared on the same land as that used for the earlier broods. I do not doubt that this has something to do with many failures. The land is tainted with the droppings, and in weather such as that experienced this summer these remain upon the surface instead of being washed into the ground by frequent rains. Again, we must not forget that the last batch of eggs in the season are fertilized with a weaker germ than these laid at the commencement, and if the germs be weaker it naturally follows that the chick is less robust, and is, therefore, less fit to stand an excess of heat, or, in fact, any strain which it might be called upon to endure. I am not naturally given to look at the black side of things, but when I receive accounts of young chicks, ducklings, or turkeys dropping off, I expect but one termination, and that is that most of the lot will fall victims before the disease or ailment from which they are suffering runs its course. It is because I believe this so strongly that I am constantly warning my readers to take care that their young stock shall receive a good start, for if they once receive a check the probability is they will not be easily got to move again, in spite of good treatment in every respect. The report of some birds recently confirms what I have just said. The sneezing points to an attack of roup; this is not surprising when we consider the changeable weather and the enfeebled condition of the birds. What people have to do is to restore the chicks to a growing state, and then they might hope to save those which are still left. I should, in the first place, try a change of food. The bread, if

soaked in water, is certain to do harm, and should be discontinued. The first feed in the day may consist of mixed middlings and Spratt's food; at eleven o'clock you may give some scraps of underdone meat, chopped very small; at two o'clock, or a little later, the first feed may be repeated, and at six some sound Wheat can be fed. An occasional meal of stale bread soaked in strong ale can be tried. For drinking purposes I should use fresh water and a little Parrish's chemical food, to be obtained of any chemist. If the chicks drink freely (and this is generally the case with silling birds), you can use cod-liver-oil to advantage. I should endeavour to divide the chicks into small lots, putting the worst cases together, then the next worst, and so on. The run should be roomy, clean, airy, and yet not draughty, nor should it be too much covered by the sun. For the worst cases it might be well to try a roup pill, made as follows: Cayenne pepper, 20 grains; copper sulphate, 10 grains; copaiba, one fluid drachm. This is sufficient for twenty pills, and half a one should be given morning and evening. The swellings and nostrils should be washed three or four times daily with Labarraque's solution of chlorinated soda, diluted with twice its bulk of water. The foregoing treatment will give some trouble with many birds, but if successful in saving the greater part anyone will be amply repaid.

TRENT VALLEY, in Farm and Home.

EARLS COURT EXHIBITION.
EXHIBITION OF GARDENING AND FORESTRY.

THE GARDEN OF LONDON.

JULY 26 & 27,
GREAT SHOW OF ROSES AND FRUIT,
CARNATIONS, PICOTEES, &c.

Classes (Open and Amateur) for **GRAPES, MELONS, PEACHES, STRAWBERRIES, CHERRIES, &c.**

Meritorious Exhibitor not named in the Schedule will be recognized. Prizes, Medals, and Certificates awarded for every Show.

All applications for entries, schedules, regulations, and further information should be addressed to Mr. H. E. Milner, the Chairman, at the Office of the Exhibition, Earls Court, S.W.

Admission to the Exhibition Building, Flower Show, and the Central and Western Gardens, **ONE SHILLING.**

Open Daily from 11 a.m. to 11 p.m.

Season Tickets, £1 1s., to be obtained from the usual Agents and the Secretary.

GARDEN FRAMES PRATT'S PATENT
 (VENTILATED) and **GREENHOUSES,**
 Patent Glazing, without Putty.

THE PERFECTION SLOW COMBUSTION GREENHOUSE.
 BOTTLE.
 Builds in front of greenhouses. Size 4 ft. 1 in. by 14 in. diam., 23 9/16 in. carriage paid. Same height, fitted with 18 ft. 4 in. piping, and Expansion Box, patent Joints, and Smoke Pipe, £3 13s. Carriage paid. Catalogue post free.

D. HORROCKS, Tyldesley, MANCHESTER.

PEDIGREE SUSSEX CATTLE (Gravetye J. Herd).—The Sussex cattle are growing steadily in public favour, both in this country and in America, where a few years ago a steer of this breed won the first bonus in the milk test (Chicago). Choice Cows and Young Stock of the best blood for sale. This herd never got up for show, but bred under the most natural conditions possible. Inspection invited.—Address: BAILIFF, Home Farm, (Hevington) near Grinstead, Sussex.

GARDEN AND PLANT PHOTOGRAPHS.

We beg to announce another photographic competition, when prizes to the amount of over Eighty Guineas will be awarded.

The subjects selected may be: Beautiful houses and country seats; garden landscapes; picturesque trees; plants, hardy and tender; Ferns; Roses; cut flowers, prettily arranged; pretty cottage gardens; our best fruits on the branch or branches, not in dishes; standard vegetables; good flower-gardens, or any other objects of interest in a garden.

LIST OF PRIZES.

COUNTRY SEATS AND GARDENS.—A prize of TWENTY GUINEAS will be given for the best series of not less than six photographs of Tudor, Elizabethan, Jacobean, or other old English houses and their gardens, particularly showing the beauty of the house in relation to the garden. Picturesque old Farm and Manor houses will not be excluded from this competition.

GENERAL GARDEN AND PLANT PHOTOGRAPHS.—First prize for the best collection of general garden photographs, SEVEN GUINEAS. Second prize, FOUR GUINEAS. Third prize, THREE GUINEAS. This series may include subjects from any class, from either outdoor or indoor gardens.

FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering shrubs of all sorts.

BEST GARDEN FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, Cherries, &c., or bush-fruits, to be shown on the branches, not in dishes. No prize will be awarded to photographs of fruits or vegetables crowded in dishes.

BEST VEGETABLES.—A prize of THREE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get full representations of the best garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such.

In any of the departments, if no collection of sufficient merit is sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea. In order to give all readers ample time to prepare good photographs the competition will be kept open until the last Saturday in July, 1893.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with the beautiful flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. The intention is to show the full beauty of the subject taken, and this cannot be done well when the photographer is confused by other considerations. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. In many of the photographs sent in for our last competition the subjects were much overexposed. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none sent the copyright of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the object shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Covent-garden, London, W.C., and marked "Photographic Competition." All competitors sending their photographs returned, if not successful, must enclose a stamp of sufficient value for that purpose.

PROTECT YOUR GARDENS. -Garden netting, fine and dressed; will not rot if left out in all weathers.

EVERYONE Who has a COTTAGE GARDEN should purchase weekly COTTAGE GARDENING

Poultry, Bees, Allotments, Food, House, Window and Town Gardens.

Weekly, 1d.; or Monthly, 3d.

OPINIONS OF THE PRESS.

"COTTAGE GARDENING" tells the cottager and amateur precisely the right thing at the right time, coming at a friendly monitor with suitable counsel.

"It is a wonderful halfpenny-worth, illustrated, and sets forth, in clear and simple English, how gardening, book-keeping, poultry-keeping, and other important cottage industries may be carried on in the most approved manner and to the greatest profit."

"It is the cheapest threepenny-worth of specialised literature on record, and should be in the hands of every man who has a few square yards of land attached to his house capable of growing anything."

"Maintains its high character, and is well worth double the price which is charged for it."

"It is the cheapest publication of its kind, and we know of none better."

"Full of useful information for the amateur gardener."

"COTTAGE GARDENING" is at once the cheapest and best of the publications which deal with the subject. We advise all allotment-holders-and there are many in these parts-to take it in regularly.

"COTTAGE GARDENING" should have a large circulation amongst allotment-holders and poultry-keepers. The mistake so often made of recommending something out of the reach of men in humble life is avoided.

"Gives in a plain, simple manner valuable information on all matters relating to gardening, and we would strongly recommend it to the attention of our readers who are thinking of growing flowers and vegetables for exhibition.

"A stout monthly paper for threepence-consists of the halfpenny weekly parts for the month, a quite wonderful work that should find subscribers by hundreds of thousands, for it deals not merely with gardening, pure and simple, but in the guide to poultry, bees, allotments, food, house, and window and town gardening."

** The August Part of this work, ready July 26, will contain a Handsome COLOURED PLATE of HYBRID BRIER ROSES.

Persons who are not yet acquainted with this valuable publication, which is having a rapidly increasing circulation throughout the Kingdom, are invited to order either the Weekly Number or the Monthly Part announced above.

HOUSE & WINDOW GARDENING.

ARRANGING CUT FLOWERS.

I was pleased to see a note on this subject in *GARDENING*, July 8th, p. 265, and thought the following notes may be useful to your readers. Some time back the late Mr. G. Phippen, of Reading, made some good remarks on this subject, more particularly in reference to exhibition. He said: "People have said to me, 'I do not care to go to the flower-show, there is so much easiness in it.'" This should not be when one considers for a moment the inexhaustible supply of varieties of plants and flowers. The compilers of schedules persist in copying each other. Why not each try and strike out a fresh line? At times we have so many hundred flowers—of Dahlias, it may be—set up in prim, green boxes, not a vestige of foliage visible, and there staged upon lengths of straight tables. At other times we have fine Asters and Zinnias staged in like manner. Then, again, at some shows we have Carnations mutilated and dressed and set up in paper collars, and staged in the orthodox green boxes on the straight table. It is a pity that these lovely flowers should be thus presented to the public! Chrysanthemum flowers are also arranged in boxes, which have to be made to a required size, so many inches long, wide, and high. If the flowers happen to be large and extra fine you must crush them into the box. Specimen blooms of Chrysanthemums lend themselves to artistic treatment. In staging, for instance, any one has thirty-six blooms to set up, and 4 feet or 5 feet run of table space allowed for the purpose. The green box should be at once dispensed with, and the flowers set with long stalks varying from 9 inches to 2 feet in length. Each flower should be placed in a receptacle which would hold water and be heavy enough at the base to prevent overturning. The flower should also have some kind of support to maintain it in an erect position. Having the flowers thus prepared, a number of suitable foliage plants should be employed—say, Feathery Palms—about 3 feet in height, to serve as a background. The flowers are then artistically grouped together with the small foliage plants—Maiden-hair Ferns, Asparagus, &c.—and edged with *Isolepis* and *Panicum*, so that the whole of the table space shall be hidden by the groundwork of plants and Ferns. The flowers rising from this would present a marked contrast to the formal box style.

C. T.

4144.—Plants for a south border under window.—If no hedging-out is to be done for this border, plenty of herbaceous plants should be put in in October, the border having been previously well dug and manured, so as to avoid disturbing the plants for some years. A selection of Roses may be made from the dwarf plants in any list, or climbing Roses put in (but "Amateur" does not say whether climbers are needed?) October is the best

month to plant herbaceous flowers and Roses, also bulbs, and the following list may be useful: Of Roses, Charles Lefebvre, General Jacqueminot, Coupe d'Hébé, Gloire de Dijon, Niphetos, and Jules Margottin, are all old, well-tried favourites, which will not disappoint. Plenty of newer kinds can be found in our rosarian's catalogues. Madonna Lilies, *Lilium auratum*, Tiger Lilies, and *L. lancifolium* species, both racemose and Kratzeri varieties, should be put in behind the Roses, as being taller. These will grow into grand clumps, and flower yearly, if well-mulched each October. Spring flowers: Wallflowers, Forget-me-nots (*Myosotis disitiflora*), bulbs of Snowdrops, Crocus, Scilla sibirica, Parrot Tulips, Daffodils, Narcissus, and Hyacinths can be put in during October, in front of the Roses, and left in the ground year by year. Also purple or white *Alyssum* makes a pretty edging in spring. Autumn flowers: *Anemone japonica* (Honorine Jobert) (white), the Pink Japanese *Anemone*, dwarf perennial *Sanflower*, *Herbaceous Phloxes* in pink, white, &c., will supply autumn blossoms, and a few groups of Carnations, Pinka, Panacea, and other summer flowers should give some brightness during the early months of the summer. The border will need a good mulching of leaf-mould and manure every autumn, and the plants should be overhauled each year in March, when they can be transplanted if necessary, cut back into shape when too large, and rearranged for the year, all but the Roses, which must not be touched at that time. Lilies and Japanese *Anemone*, too, do object to be taken up, and do best left alone.—I. L. R.

4198.—Plants for windows.—On a north or north-west aspect hardy Ferns and Creeping Jenny thrive better than most things, and both are good town plants. A few Pansies might be planted along the front of the boxes. Other suitable subjects for such a half-shaded position (during the summer) are *Fuchsia*, Shrubby *Calceolarias*, and *Celtis occidentalis*. In the west windows "Geraniums," both of the common or Zonal and the Ivy-leaved sections, *Marguerites*, *Heliotropes*, and *Tropaeolum* would do well, and a few Tuberosus *Begonias* also might be tried.—B. C. R.

4123.—A house border.—Almost any hardy creeper can be grown on a south exposure unless the house be in a city, when the impure air would prevent most Roses from doing well. The Gloire de Dijon Rose will, however, stand a good deal, and nothing can be better than this as a climber, with *Keine Marie Henriette* (the Red Glory), *William Allan Richardson* (apricot-tinted), and *Climbing Niphetos* (pure white) for variety. A selection of good *Clematis* plants might be made, placing the large-flowered varieties in the warmest place, and the White *Clematis Montana*, in the coolest. If a good plant of this is put in from a pot now, it will make a good start next year, and soon cover a large space. The lovely *Wistaria* grows rapidly when established, but usually takes a year or two to do this. *Ampelopsis Velutina* is indispensable for its great beauty, and double *White Jasmine*, French *Honeyuckle*, and *Virginia Creeper* are all worth growing. Much depends upon the preparation of the border,

which should be thoroughly dug and well manured before anything is put in; careful planting, too, in the autumn (October), or early spring, will be necessary. Many ignorant gardeners will make a hole for a plant without digging the ground, and drop the roots in perpendicularly; then the poor thing has a hard struggle for life, and cannot manage to make the luxuriant growth which is necessary. In turning a plant out from a pot the lower roots, which will be found coiled at the bottom, should be loosened with care and spread out on well-prepared soil about six inches below the surface, in a fan shape, covering them with a little fine sandy soil, without allowing manure to touch them. Having trodden the surface, after covering the roots in, until the plant is firmly planted, a mulch of stable-manure, 3 inches or 4 inches deep, may be placed over them; this will prove a protection from severe frost in winter, and from dry heat in summer, and the Creepers will flourish accordingly. With regard to the second part of the question, as to a selection of plants for making the border gay, not much can be done until October, when dwarf Roses, Evergreen *Barberries* (*Berberis Aquifolium*), with plenty of spring bulbs, such as *Crocus*, *Snowdrop*, *Scilla sibirica* (bright-blue), *Tulipa*, and *Hyacintha* will make a bright show in early spring. Dark-red *Wallflowers*, *Forget-me-not* (*Myosotis disitiflora*), and a good selection of *Primroses* will add to this, and these, too, can be planted in October. When they get out of bloom in May plant the border with handsome bedding plants for summer, such as *Zonal Pelargoniums*, *Fuchsias*, *Heliotropes*, *Gazania*, *Lebelia*, &c., and have a reserve bed of *Asters*, and another of *Early Chrysanthemums* in the kitchen garden, where these plants can be cultivated until they show colour in autumn. They will both bear careful lifting at that time, and can be used to make a late autumn display under the house with great advantage.—I. L. R.

4193.—Roses in a window.—As soon as your plants are out of bloom stand them in some sheltered position out-of-doors. Keep them properly supplied with water, as clear as possible from insect pests, and either plunge them under the shelter of a hedge during the winter, or else afford them the protection of a cool frame or pit. A very little protection is all they need, and they may be started again in March. Roses are not ideal winter plants, being much subject to insect pests, and requiring a great deal of attention in the matter of syringing, &c.—P. U.

4108.—Herbs for winter use.—Mint, Sage, Thyme, and Marjoram, should be gathered in August while they are at their best, and each variety placed in a separate paper bag. These bags can be put into the oven when it is cool in the evening, and taken out in the morning when the leaves should be crisp and dry, but not burned. Rub them up finely, keeping each kind separate, and place the powdered leaves in glass jars, such as are used for jam. If kept in a dry cupboard, tied over with paper, the dried Herbs will be useful all the winter, or can be used as they are needed.—I. L. R.

GARDEN WORK

Conservatory.

Freezia, Roman Hyacinth, and Lilium candidum should be potted for forcing. The last-named Lily is coming more into favour for pot-work, and there is, I think, less demand for Lilium Martini. Only strong healthy bulbs should be potted. Work plants of their seed and other porous material into the potting compost. In this healthy root-action will take place, and strong spikes with healthy foliage will follow. Plunge the pots in the open air till October. The Roman Hyacinth and Freezia will be moved indoors in September. Onions in pots will be better placed outside now in the sunshine to ripen growth. As the ripening process proceeds less water will be required. The large-growing Cactus (Cereus grandiflorus) makes a very conspicuous plant in the conservatory border. I once had charge of a conservatory in which an immense specimen was planted, and tying of which was a work of considerable difficulty. The plant was 12 feet high, and bore in the summer many hundreds of scarlet blossoms. Passion-flowers and other free-growing climbers are both useful and ornamental in large houses. They are useful in affording shade, and the blossoms, which are freely produced, have an interest besides the mere show produced, and by-and-by when the shade is no longer required the growth can be gradually reduced. The food of peat and loam in which Lapagerias are growing must not be permitted to get dry. I have seen this plant to do well through being planted on the sunny side of the house. The Lapageria will do very well in the north house. Hot sunshine at any time is bad for it. Everybody should grow some of the greenhouse Rhododendrons. They are charming plants for the conservatory house, and they succeed well when a little shade is done. When grown in pots and the growth made early, and afterwards ripened by exposure in the open air, they will flower very freely in the warm greenhouse. Should be potted chiefly in peat and sand. The plant should be plunged outside in a bed of Cocoa-nut-fibre now, but must not be allowed to suffer for want of water. Countess of Derby, Countess of Bolton, Duchess of Edinburgh, Duchess of Devon, Edgeworth, Lady Conyngham, Lady Hamilton, Lord Walsley, and Prince of Wales are all good, and worthy of attention for cut-flowers or to beautify the conservatory. Gonolias and Heath should stand on ool-sash beds thinly in some open position to get the growth well ripened and the blossom-buds in course of formation. Solanum capensestrum must now stand thinly outside to set the berries. Arum Lilies in pots should be shaken out and re-potted. No doubt some of the stock were planted in June, and these if watered regularly will make very strong plants; but they hardly bloom so early as those plants kept in pots. Any plants which are likely to require more pot-room should have it given now, so that the roots may occupy the new soil before winter. Correa, Selvia, Eupatorium, and other things planted out should be stopped for the last time.

Ferns under Glass.

The plants are growing freely now, and must be opened out to afford room for the fronds to develop. Having room many plants in proportion to the space is a great evil, because it is next to impossible to have them thin in form. Some of the hardest species may be taken to the conservatory, and in a warm summer like the present if there is a sheltered dell anywhere in the grounds special features may be created by plunging out some of the hardest specimens. Nephrolepis in variety, the Bird's-nest Fern (Asplenium Nidus-avis), some of the Tree-Ferres, and others may be plunged out in very sheltered spots where the wind and sun cannot reach them. The indoor fernery may be made more interesting by a few Brazeos, Crotona, Begonia, and other plants with colored leaves being introduced. Grasses, such as the Variegated Carex and others, have a graceful effect. Ferns will still require shade and moisture in abundance. In potting use more loam than peat, especially when it is necessary to keep the plants in comparatively small pots.

Stove.

Fires must be lighted on cold nights, as a cold, damp-laden atmosphere will soon injure tender foliage. All-mandas now and other creepers will be in fine condition. Most of these plants will benefit from liquid-manure, being applied, say, twice a week, till the last flower-bud expands. Winter-blooming stuff will be quite safe yet in pits and frames, ventilation being given during the day to harden the growth. Poinsettias must be kept near the glass, and must never suffer for want of water, or the better leaves will go. Do not forget that a demand will be made for wall-growth but not large plants for dinner-table work when the loam season is over and the rub is made into the country.

Hard-wooded Plants

must stand on an impervious bottom; if worms get into the pots the drainage will soon be blocked up, and water-logged plants soon get into a wicky condition, and then might be as well thrown out. The water is the principal work done, and the plants will be in the open. Never water a specimen plant without first tapping the pot and testing its condition. Asters are rather subject to thrips, and any plants which are attacked should if possible be cleared before the plants are taken indoors again. If the plants are not too large a tub filled with root and lime-water, into which the plants can be dipped, will make use work of the insects. This is a very simple and cheap mixture. The roots are tied up in bag, and plunged in a tub of rain-water. The bag is stirred about daily for a week, and then a couple of pounds of new lime is dropped in the tub and left to clarify; in a couple of days the liquid will then be clear and about the colour of sherry. A quart of this to six quarts of water will make a very good dipping or syringing mixture.

Mushroom-house.

Unless in a very cool position Mushrooms will be more or less stagnant in bedding now. So much is the case generally that beds are made up in the open air in May

and June to produce Mushroom in the hot weather, and even in the open air to obtain good Mushrooms the situation for the beds should be as cool as possible. The north side of a lofty wall has good place, and I have had good beds on the north side of a group of belt of trees. As soon as the house has ceased to produce good Mushrooms clear all the beds out and all rubbish or litter of every kind, as such matters only form breeding and hiding-places for woodlice and other insects. Before any beds are made in the new house have the walls thoroughly cleaned with lime-wash, and saturate all the crevices in the floor with boiling water.

Window Gardening.

There is less demand for flowering-plants now. Foliage is now in the ascendant for the time, and the green and graceful Fern always finds favour when something is required to rest the eyes upon. Pteris tremula is one of the very best Ferns for the room; then comes Pteris Ovaroides and P. cretica, P. nobilis and others. Polypodium anatum, Nephrolepis exaltata, Asplenium Nidus-avis, Adiantum, and others are also most useful.

Outdoor Garden.

The long drought has weakened the Grass on the lawns, and a sprinkling of artificial manure will be very beneficial now. Nitrate of soda, guano, or bone-meal will do. Now that rain has come fairly copiously things will put on a better appearance. The question is sometimes asked can there be a bright garden without bedding-plants? Well, the bright garden will have great value this season but the tender bedding-plant in it. The Tufted Pansies have stood the drought better than I expected, as we are apt to associate Pansies with a demand for coolness and moisture. Land which is made fertile with manure as required will support the plants in a difficult season, and enable them to blossom freely. In short, good gardening is pretty much a question of helping the land to do its work. The recent rain has loosened the soil of the rougher spots of the Standard Birch and budding may now be done. Dwarf Briers and Menziesia may be done later; but the standards should be done as soon as they will work. Climbing plants, such as Clematis, Vetch's Crapnet, Jasmine, &c., established in pots may be turned out now against walls. I would rather plant now than wait till autumn or spring, as there is some growth left in the plants yet, and they will get well established in the soil. Cuttings of the New Zealand Veronica will strike now under a hand-light in the shade. Cuttings also of Eucalyptus and choice evergreen shrubs will strike now under glass kept moist and shaded. In my opinion it is the best season to put Rose-cuttings under glass.

Fruit Garden.

Peaches under glass from which the froit has been gathered must be watered as the roots when necessary, and the foliage must be syringed daily or washed with the engine. Give all the ventilation possible night and day. The wood is hard and firm, so there should be no difficulty in getting it thoroughly ripened. Remove all late laterals promptly. Late Peaches just beginning to put on colour must be fully exposed by the removal of foliage, if necessary; the same attention must be given to Peaches on walls, so colour is nearly essential in Peaches, especially now everybody does a little market-fruit. I have been much interested in a plantation of Bush Apples on the broad-leaved Paradise. The trees are four years planted and are carrying a good crop of remarkably fine fruit. They seem to have enjoyed the sunshine and are a happy contrast to most of the orchards in the district. I should state there has been much talk of venturing into the woods. These are the trees for the small garden, all the attention they require is mulching in spring with good manure, and the thinning of the young growth where there is any appearance of crowding. Good Strawberry-plants will be scarce this year as fewer runners have been produced and these are weaker than usual, therefore it is important to get the land into the best possible condition. Where Pines are grown the plants should be gone through now, plimbling beds renewed, and any potting in Peaches, especially now. Remove suckers from old plants from which the fruits have been out. For the suckers after dressing the bottoms in 6-inch pots and plunge them in a warm-bed and keep close. Shade a little when the sun is very bright. Give liquid manure to plants swelling off their fruit every time they are watered until the fruits begin to colour. Ripening Pines will not require much water, though the atmospheric moisture must not be altogether neglected. Plant Pines for a while in a warm house or pits. Young plants with a long trellis to cover should not be stopped as in frame culture.

Vegetable Garden.

Thin the growth of Tomatoes both under glass and also outside, not only by thinning off all side shoots, but also back foliage to one pair of leaves. Feed liberally with rich manure and strong liquid. Tomatoes are good feeders and if planted in fairly firm ground cannot well have too much special nourishment. Put in cuttings or sow seeds to raise plants for carrying through the winter. Young plants of Cucumbers should also be raised either from seeds or cuttings for winter-fruiting. Cucumbers in bearing should be exposed to the sun as far as possible, but have been using for this purpose Moss-litter-manure and fresh loam, and I have never had Cucumbers do better, but the sunshine has brought Cucumbers on with a rush. I suppose there never has been a better Cucumber season where the treatment has been liberal. Now that rain has come copiously promote Winter Greens. Late planted stuff, as a rule, does not do much good, but the ground being warm and the prospect of autumn now favourable, there has been planted things may do better this season; at any rate, where there is vacant ground fill it up with something. Plant out Coleworts. Savoy Cabbage may also be planted, also late Celery. This crop will come on faster now. Dig up second-early Potatoes and sow Turnips, Spinach, and Onions on the land. Plant Walsherb Cauliflower on a south border. Cut and dry Herbs. Sow Parsley and French Horn Carrots. The latter will come in useful for drawing young. E. HENRY.

Work in the Town Garden.

There are in a great beauty just now, and have not had up wonderfully since the rain, though it has been quite earlier than it did so doubt the blossoms would have

been finer. Where Roses cannot be grown, and in very few towns or even suburban gardens (except where right on the edge of the open fields) do they thrive to any extent, there is no substitute for them to equal Cascarillas. The colours are so varied and rich, and the blossoms (of most kinds at least) highly fragrant as well. They are capital for flower beds, enjoying a liberal supply of root or manure material of any kind, the root, though I do not suppose that the pepping they frequently get overruled in a crowded neighbourhood does them any good. The chief secrets of their growth are a free, sweet, and moderately rich soil, preferably of a loamy nature, and moderate firm, and annual propagation by means of layers. The earlier these are taken the better, so no time ought to be lost now in getting the whole of the work completed. This has been a bad year for Hollyhocks, which dislike drought of all things, and I do not think I have seen a decent plant this season so far. I lost all my old plants last winter, owing to the intense cold and wet together and the soil being somewhat heavy. I usually make a sowing in heat in January, but omitted to do so this season; shall, however, get a good lot in shortly, wintering the plants in pots under glass and planting them out next spring. One of the strong points of this site is the soil, with which it is raised from sand, and if this was carefully sowed from fine flowers a large portion of the progeny will prove to have good double blossoms also. Dahlia ara growing rapidly, and in some cases showing flower. Keep them securely staked and tied, as they soon become top-heavy, and if the growth get at all crowded thin them out fearlessly. In town gardens the only way to get plenty of Dahlia blossoms is to give the plants the smallest portions available and keep the growth well thinned out. Dahlias grow in large pots are very useful for balconies, that roofs, broad steps, and other places where they cannot conveniently be planted out. In smoky localities where few things thrive the Tropaeolum family are of great use. Every one knows what an accommodating plant the common climbing Nasturtium is, and the dwarf annual kinds, such as King of the Bees, etc., are equally valuable for bedding. There is a race of dwarf perennial varieties, increased by issues of outtings, that are most excellent town plants, and F. Firsielli may be planted in hanging baskets and window boxes, or in the open ground, the growth being trained to sticks. B. C. R.

THE OMINO WEEK'S WORK.

Extracts from a garden diary from July 29th to August 5th.

Sowed a little more seeds of Eilan's Early Cabbage, also Tripoli Onions, and Prickly seeded Spinach. Finished the pruning of Wall-trees and Espalliers. My Apple-tree which I have noticed for the first time had a little American Blight upon one or two branches, have been dressed with Gishurst Compound, every bit of the white flaky insect being washed with it. It is difficult to say how far the insect will travel. In the present case they must have been carried by the wind. Put in cuttings of Fuchsia. They will root in a clove frame and will then be potted off and kept growing in heat all winter, and will make good flowering plants in 5-inch and 6-inch pots by midsummer; or in the case of early blooming kinds a month earlier, or if the flowers are picked off and the plants shifted on into larger pots, will make a nice little specimen a yard high by July. Have some of the plants struck about this time last year, now in 7-inch and 8-inch pots, masses of bloom, very useful for grouping in the conservatory. Shifted on Aralia Sebaldii and Orevillea robusta. These are raised from seeds sown in spring. Put in cuttings of Hydrangea, as the young shoots are getting a little firm. The plants will bloom in the spring in 4-inch pots, each plant carrying a large truss of bloom. Cleared out the early Cucumbers in heat. Every scrap of soil and manure has been taken out and the house will be painted very shortly and be got ready for planting in about a month to come into bearing through the autumn and winter. Young plants of Lookie's Perfection are just up and will be strong and ready to go out by the time the house is ready for them. Cucumbers in bearing are gone through, old leaves removed, and young shoots stopped once a week through the season. Applications are applied as often as the roots work through and show themselves on the surface. Sowed Brown Cos Lettuces and Green-curled Endive for winter. Planted a fresh piece of ground with Strawberries, the kind being Sir J. Paxton and President, with a small trial bed of a few new sorts. Tied up Celery with paper to blanch. Cleared off old Peas and planted the ground with Coleworts, about 1 foot apart. Shifted on Cinesarias and Primulas and pricked off Cinesarias in boxes of light rich soil. Rearranging the stove to give plants more room, several plants being moved out to the conservatory. Shifted spring struck Begonia, Justicia, into 6-inch and 8-inch pots. A few larger pots have been used now, and in some cases three plants being placed in each pot. It is quite an easy matter to make up good specimens in this way with spring-struck stuff and may will produce a much better crop of work and be also other more than the roots work through out down. I force a good many of the old White Lily, and the bulbs are reported as soon as the old stems die down. Only the strongest bulbs are selected, the small bulbs are planted out in a reserve bed. The Double Tiger Lily does well in pots. Half a dozen bulbs in a 7-inch pot make a nice specimen, and this I find very useful in the conservatory after the Madonna Lilies are over; in fact, I have them in bloom now. My stock of early-blooming Lily (Yellow) is now in a cold frame with the light off and the soil on. Exposure rests and ripens the bulbs and secures plenty of spikes. Shifted on Tree Cascarillas for winter flowering. They will remain outside for the present. Put in cuttings of Fuchsia and Viola or Tufted Pansies in cold frames, the beds being especially prepared with lights for the winter frosts. Shifted on double Primulas, also a batch of Primula obconica.

4152.—Legal question.—If the branches of the tree grow over your neighbour's garden it is an infringement of his rights, or an obstruction the light and air, and he is quite within his rights to remove them. It might perhaps have been more properly and as requested you to do so in the first instance. (18 CA)

* To cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than in the south, and with a quantity of earth.

ROSES.

ROSE "LAMARQUE" IN COOL-HOUSES.

This, in addition to being one of the very finest of wall Roses, is lovely for planting out in a greenhouse or any other cool glass-house. It used to do wonderfully well in one of the cool-houses in the Royal Nurseries, Sloagh, bearing a great crop of delicate White Roses overhead. It is very free and graceful, and the buds are valuable, as they have a good clear line from their earliest appearance. It forms a charming contrast to Maréchal Niel when planted out in the same house.

THE POLYANTHA ROSES.

The Polyantha class is one of the most charming of the various sections of Roses. The latest addition to the list is Crimson Rambler, a variety that promises to become one of the most largely grown varieties of the future. It is so exceedingly free, graceful, and the flowers, quite little rosettes, are of an intense crimson. It will climb and make a good mass, simply for the reason that its splendid flowers are so rich and striking in colour. The Polyantha Roses keep the garden gay over a good season, and the dwarf plants

and one is Georges Pernet, which has rosy-peach flowers, distinct and pleasing. Golden Fairy has a dainty bud, and the flower is buff-yellow, varying in shade. The Polyanthas may be grown for cutting, and the clusters of bloom are excellent for vases or to mix with other things. The plants are not troublesome to grow, bloom continuously, and exhibit such distinctness of character that several may have a place in the same garden without introducing a monotonous effect.

C. T.

OLD ROSES STILL IN CULTIVATION.

Roses introduced more than a quarter of a century ago, and which are still appreciated, must be worth looking after by those who merely want a garden full of Roses. Who would care to be without General Jacqueminot, so sweet for cutting either under glass or against a wall outside? The General was introduced in 1853, just about or a little before the time of the Crimean War. Géant des Batailles, introduced in 1848, or perhaps a little earlier, was thought a good deal of at that time, but is so liable to mildew, and is out, I think, so much grown now; still in well-drained situations it will make a good bedding Rose. I remember distinctly

is still to the fore, though introduced so long ago as 1830. Solfaterra, 1843; Rubens, 1859; Adam, 1833; Céline Forestier, 1858; Devoniensis, 1840; Elise Sauvage, 1843; Cloire de Dijon, 1853; Homère, 1859; Lamarque, 1830; Mme. Falcot, 1858; Mme. Willermoz, 1845; Mrs. Bosanquet (China), I forget the date of introduction of this useful old wall or pillar Rose, but I think somewhere about 1850; Souvenir de la Malmaison, 1843; Souvenir d'un Ami, 1846; Triomphe de Rennes, 1857. These may be termed the remnants which remain from the hundreds which have been introduced since 1840, and which have disappeared. I am speaking of the old Roses only. Doubtless many of the newer Roses now in cultivation will still be found after many years in most gardens. Such Roses as Ulrich Brunner and Gustave Figanau will doubtless be in evidence in the twentieth century.

4138.—Budding Briars.—Bud the Briars as soon as the bark works freely. If the thorns can be easily detached, the bark will move easily.—E. H.

—Bud the Briars at once; you cannot have a better time than the present. You can use buds of H.P. or any other class of Rose, and if the plants are standards the buds must be inserted on side-branches springing from near the top of the Briar.—B. C. R.

—Yes, the present time is an excellent one for budding Briars that were planted last October. No doubt you have paid due attention towards removing any side-growths that were above or below the height you wish the future Rose to be. This is necessary, so as to secure strong shoulders to work the Rose-buds into. Do not cut away any of the growth previous to, nor directly after, inserting the bud. This is one of the chief causes of failure, as it checks the even flow of sap at a most critical period.—P. U.

4211.—Ground for a Rose-garden.—From the description I should say Roses would do well with you if you add a little heavier soil to your garden. The fact that Roses do well just below you, and upon the same slope of ground, would confirm this. No Roses are more profitable to grow, or more handsome and varied in colour, than the Tea-scented and Noisette sections, and as these would evidently thrive well with you, why not confine your choice rather closely to these? Yellows and lights of all shades are found well represented among the Teas. They grow more freely, flower in greater profusion, and are altogether the best class to grow. They also make far better plants as standards than the majority of other sections do.—P. U.

I see no reason why your hopes of succeeding in growing Roses in such a soil as you describe should not be realised. There is no doubt Teas would do better than the H.P., but the latter as standards on 2 feet stems and as dwarfs would no doubt thrive well if you keep up its present state of fertility by digging in lightly a moderate dressing of manure once in two years, and allowing the Roses to have the benefit of all the space. The beds should be oblong in shape and about 6 feet wide. In a dry soil and sloping position like yours, the surface of the bed should be level, and 2 inches or 3 inches below the walks or alleys between them, all the water you give them will then find its way down to the roots. In raised beds it is liable to run away down the sides. The H.P.'s had better occupy the beds at the bottom of the slope.—J. C. O.

4194.—Roses for India.—It would be the best way to give an order for the number of plants you require, placing it in the hands of some good nurseryman. If you do this, and say when you call, the grower will pack them in such a manner as his experience has proved most successful. There are many thousands of Roses grown in this country and exported to India annually. The extra charge for packing would be a mere trifle. Buds and cuttings could not be taken, as the journey is too long.—P. U.

4268.—Treatment of Roses, &c.—When you say that Ulrich Brunner is very poor, and that the flowers of John Hopper are small, it is very plain that the long drought is the cause of your disappointment, as all the varieties you mention are good growers, and often thrive where some of the weak ones fail. With regard to the colour of the Countess of Rosebery changing, as you seem to suppose, it is attrib-

Flowers of Rose "Lamarque."

are usually in the summer quite sheathed with flowers. A very fine kind is Gloire des Polyanthas, the flowers bright-rose, white in the centre, and when a plant is in full bloom it is exceedingly distinct and pleasing. These Polyantha kinds are not grown much in the smaller gardens, although it would be better so than having a lot of ugly standards that never seem happy. One reason is they are being constantly one about and never given a reasonable chance to make a respectable head. One of the more popular Polyanthas is Mignonette, which has delicate rose flowers, that change with age to white. It produces charming clusters, and in every way is a delightful variety. One of the freest is Anne Marie de Montravel, the flowers appearing in profusion, and if small they are very pure-white and imbricated in character. Clothilde Soubert has large flowers, considering the class to which it belongs, and there are white, with the centre tinged with a reddish tint; they are full, imbricated, and given to sporting a little. The Paquerotte is a gem of its class, the plants being very free, and the flowers double, pure-white, and very pleasing. There are upwards of twenty kinds described in catalogues, but in the ordinary garden this number is not, of course, required. But I may mention two or three more of great beauty

the grand masses we had of it in 1850, all in their own roots, struck from cuttings principally from single buds in heat. The following list with the date of introduction may be of interest: Alfred Colomb, 1865; Anna Alexieff, 1836; Anna de Diebach, 1858; Barocess Rothschild, 1861; Beauty of Waltham, 1862; Boule de Nalge, 1867; Camille Bernardin, 1865; Charles Lefebvre, 1861; Comtesse de Chabrillant; 1856; Dr Andry, 1864; John Hopper, 1862; Jules Margottin, 1853; La France, 1867; Mme. Charles Crapet, 1859; Mme. Clemence Joigneux, 1861; Mme. Charles Wood, 1861; Mme. Victor Verdier, 1863; Miss Bonnaire, 1859; Maréchal Valliant, 1861; Pierre Notting, 1863; Mario Baumann, 1863; Prince Camille de Rohan, 1861; Sénateur Vaissas, 1859; Victor Verdier, 1859. Among Tea and Noisette Roses some of the favourites of the present have a still more ancient record. Niphotos, for instance, was introduced in 1844. A long list of really splendid Roses might be given which were introduced much over a quarter of a century ago. Goubault is the first Tea Rose I remember anything about, and has fixed itself in my memory because somewhere in the forties I was working in a garden where several plants of this very fragrant Rose were introduced from France. Ladies often went to France for their Roses in those days. Safrano

able entirely to the heat and drought. If you want to catch the true colour of *Rosee* in such a season as we have passed through, you must see them in the morning before the sun has had time to cause them to fade. The best *White Rose* for cutting is *Perle des Blancs*, as it is a good perpetual bloomer. Two good standard *Rosee* with light-coloured flowers are *Rève d'Or* and *Sonveur de la Malmaison*; these, however, are not Hybrid Perpetuals. If you prefer the latter class you may select *Captain Christy* and *Mme. Gabrielle Luizet*.—J. C. C.

THE KITCHEN GARDEN.

RADISHES AND THEIR CULTURE.

FOR our first Radishes we were indebted to China, whence they were introduced into this country about the fifteenth century. Their value was at once recognised, and they soon spread over all parts of the country, until even the smallest cottage garden had its bed of Radishes. A warm, moist soil suits them best, but they may be grown in any ordinary garden soil. Sowings may be made from February to December, but both early and late crops must have the warmest border available, and be protected during severe weather, whilst summer crops may be advantageously grown in any shady position. The seed is generally sown broadcast, and the seedlings thinned out when large enough to handle. These thinnings, when washed, make an excellent salad, and are by many preferred to the root. From April until September sowings may be made every ten or twelve days—i. e., if a continuous supply be needed. To have Radishes in the best possible condition they must be grown quickly, and to do this frequent waterings during dry weather must be given them, otherwise by the time the roots are of a usable size they will generally be pithy and ill-flavoured. Small sowings in quick succession are, therefore, preferable to large ones made at long intervals apart. Where Radishes are forced, the seed is generally sown on hot-beds between rows of Potatoes, Carrots, &c.; or where there is plenty of accommodation, they may be allowed to occupy frames by themselves; the former plan is, however, a good one, and the Radishes are not detrimental to the other crops, being used before they have attained a sufficient size to be injured by them. In this case the seed is sown in drills, and the seedlings, when large enough to handle, are thinned out to distances of about 1 inch apart. Frequent waterings and weedings are all that is necessary after the plants have been thinned. Radishes may also be successfully forced by sowing the seed in large boxes filled with light, rich soil, and placed in warm-houses or pits. As regards varieties, they are now numerous, those most in use being the Turnip-rooted kinds (for forcing and early crops out-of-doors), the long-rooted sorts, such as Wood's Early Frame and Early Scarlet Frame (see illustration), Scarlet Short Top, &c. These are all good in flavour, and bright scarlet, a colour which renders them more valuable than the purple and white kinds, which are only fit for growing for their leaves, which are large and tender. The Turnip-rooted kinds are most suitable for summer use; there are several varieties which, however, differ but very slightly from one another except in colour; there are scarlet, white, rose-coloured, and purple, the two former being the kinds generally grown. The Black and White Spanish are grown for winter use, these sorts being much more hardy than other kinds, but they are inferior in quality, being large, hard, and hot. The only Radishes grown in the market gardens about London are the

RED TURNIP and Salmon (a long-rooted kind), and the white varieties of both these sorts; but the majority are red. These constitute the principal winter crops in the market gardens, the first coming in in the first or second week in December, the second three weeks later, the third in the second or third week in January, and others from that time till the end of March or middle of April, an interval of about three weeks elapsing between each succession. The empty space at command, the character of the season, the succeeding crops, and other circumstances determine the number and extent of the Radish plantations. Where a great extent of land can be obtained and sown at one time, the sowings are fewer

than when only a small space can be cropped, and where, on an average, four or five successive plants constitute the number grown. Radishes do not grow well in summer, the weather being then too dry and parching for them; but in a moist season they may be grown even in summer with advantage. If the weather be moist, a

Radish "Early Scarlet Frame."

sowing is made in August on a cool piece of ground, and another a fortnight or three weeks afterwards. Radishes are usually grown on ground that has just been cleared from Vegetable Marrows, French Beans, Seakale, Rhubarb, or Celery. The first two crops are usually grown under fruit trees; by sowing-time the trees are leafless, and whatever pruning they may have required will have been given them; they, therefore, do not shade the plants, but, on the contrary, shelter them a little, and before the leaves begin to grow in spring the Radishes are marketed. The ground, after having been dug or trenched, and manured if necessary, is lined off into 4 feet or 5 feet wide beds, having 1 foot alleys between them. The seeds are then sown, raked in with wooden rakes and also slightly covered from the alleys, and rolled. About 3 inches in depth of rank litter are then strewn over the beds, and left there until the seedling appear, when, if the weather be fine and not very frosty, they are uncovered during the daytime and covered at night; but during hard, frosty, and snowy weather, they are kept covered, even during the daytime. All the sowings are treated in the same manner as regards coverings and uncovering; and, after the middle of February, if the plants be strong and the weather mild, the coverings are dispensed with, but kept in the alleys in case of emergency. Radishes, in their rough leaves, will stand a few degrees of frost with impunity, if the ground be not very wet. In April, the litter used in covering is removed and built into a large stack, to be converted into manure. The

MARCH AND APRIL SOWINGS require no uncovering. Birds are very destructive to Radishes from the time of sowing until the plants have made rough leaves: they eagerly devour the seeds before they germinate, and look after the husks after the seedlings appear, pulling up the young plants to effect their purpose. In order to counteract this mischief, boys are kept to watch and scare away the birds. In March the first outdoor Radishes are fit for market, the largest being pulled up first, leaving the others for a week or two later, in order that they also may become marketable. When drawn they are tied into little bundles, bound round with a withy, or piece of bast, washed after being bunched, and packed into baskets for market. After Radishes may be planted Seakale and Lettuces, Cauliflower and Lattices, preparations being made for Celery, Vegetable Marrows, French Beans, or any other crop suitable for the situation.

Radishes are treated in the same way as those for spring use; but, as has been stated, the litter coverings are not used except in the case of hot, dry weather. When Radishes are wanted earlier than those of the December outdoor sowings, they are obtained from gentle hot-beds, made up about the 1st of January. These hot-beds are of two kinds—one the common frame hot-bed, the manure being in sunk trenches; and the other merely a sunk bed of manure, covered with a few inches of soil, and mulched over like the outdoor beds.

4212.—**Extirpating Horae radish.**—You cannot do better than you are now doing to get rid of the Horae radish; in fact, that is the only way to do so. If you continue it you will not find it so difficult as you suppose, for no plant can stand being interfered with while in active growth, as you are now doing. For a year or two plant the space with Potatoes, or some other strong growing crops, like Celery or Peas, that do not remain in the ground, and that require the land to be deeply stirred, with plenty of space between the rows.—J. C. C.

4191.—**Unhealthy Marrows.**—There are probably insects at work, which cause the puckered and warped condition of the growth. Syringe with soap-suds and paraffin-oil several times, and keep the plants well nourished with mulching and water. Possibly, in addition to the insects, there may be mildew. In that case dust the affected parts with sulphur; then, if the roots are well nourished, the new growth will be clean.—E. H.

4209.—**Unhealthy Cucumbers.**—The plant is affected with canker, probably caused by irregular watering, or by moisture settling round the collar of the plant. This part should be kept high, and be wetted as little as possible; and it is also a good plan to have a few pieces of charcoal, free-stone, or broken brick round the neck of each plant, so as to avoid anything of the kind in future.—B. C. R.

Your plants are affected with canker, the worst of all diseases that can attack Cucumbers, and for which there is no remedy unless it is applied immediately the disease appears. A little sulphur or fresh lime rubbed on the affected parts will check its further progress if taken in good time. You had better draw the earth away from the stems and apply the remedy as suggested, and do not let any moisture reach the stems of even healthy plants when this disease is known to be present. In future get a change of soil.—J. C. C.

4185.—**Cracks and dark spots on Tomatoes before ripening.**—Cracking is usually caused by insufficient moisture during the early stages of growth, and a superabundance afterwards. It is very likely to occur in a season like this, when frequent and heavy rain succeeds a long period of drought. A black spot commencing in the eye of the fruit and gradually spreading is a disease caused by the style of the flower becoming decayed instead of withering naturally; but another kind of decay sometimes appears on the plants, and this I believe arises from excessive moisture in the house at night, or from want of vigour in the roots.—B. C. R.

—This is a fungoid disease closely allied to the Potato disease. I should hardly have expected this in a season like the present, unless the plants are growing under unfavourable conditions. When Tomatoes are grown year after year on the same spot they are more susceptible to the attack. A damp, stagnant soil often leads up to it. If the plants are in a cool house deficient ventilation and too much water may have brought it on.—E. H.

4132.—**Culture of Seakale.**—I would advise "Ignorant" to dig up his Seakale in autumn when the leaves have ripened off. Cut off the roots and force the crowns in a greenhouse in winter, or in a frame on a slight hot-bed, and make a new bed in the following March or early in April. The roots which were cut off may be made use of; every piece will grow. Choose pieces which are clean, without those black spots which are seen on a transverse section running through them, not smaller than an ordinary *Garlicum stem*; they should be selected at the time of digging up. The end nearest the stock should be cut off horizontally, the root

and chliquely. These are known as thongs; they must be kept moist by a covering of soil or sand in the same way as Carrots or Beet. In preparing the ground incorporate plenty of good manure, as good Seakale cannot be grown without it. Trench the ground well, keep the top spit on the top, and chop and rake down. If intended for a permanent bed, plant 3 feet apart each way, three thongs in a triangle, 4 inches apart, 1 inch below the surface; when the shoots can be handled thin out to two on each thong. Keep clear of weeds by occasionally chopping through with a three-forked hoe. A good watering two or three times during the summer with manure-water will benefit them greatly. In autumn cover with pots; these should be covered with leaves. In this case put some wire netting round 3 feet high; fasten to stakes. Fine crowns should be ready to cut by March; if required earlier some manure which will give a little warmth should be covered over them. When cutting out the crown clean off. Afterwards the stocks may be cut farther back, so keeping the crowns more compact. When the thinning-time comes more can be left, from about eight to twelve. I have out fourteen fine pieces from a single pot, this being rather exceptional. After the leaves or manure is cleared away a coat of manure should be dug in; a bed should last about four years. If thongs are planted 2 feet apart and 9 inches to a foot apart in the row and thinned out to one crown, they can be dug up in autumn and forced in winter; good crowns are obtained in this way.—G. P. SELDEN.

4201.—Forcing Rhubarb.—Rhubarb may be forced under the stages in the greenhouse if the stages are not too low. Set the roots close together, and fill in between with rich compost, and give a good soaking of tepid water. The roots must be healthy and strong. Weakly roots which have been divided this year will not do.—E. H.

FRUIT.

EARLY APPLES.

One of the best early dessert Apples is the Red Astrachan, a very handsome and free-bearing dessert kind, quite fit for table this year early in July. This is closely followed by the Junnatsinge and Red Quarrendan, and then by the highly-perfumed Gravenstein; after which there are plenty of good kinds to take up the supply. For kitchen use Lord Suffield (here figured) is again the first and best, carrying a fine crop of clear-skinned Apples of excellent quality that require but very little cooking. Keswick and other Codlins are all good cookers and exceptionally prolific. In seasons like the present, when heavy crops and dry soils are the rule, it will be well to lighten the load as much as possible by taking off the largest fruits first, so as to make the most of the crop. Where mulching and artificial watering can be given to the trees it will well repay the labour. J. G., Hants.

4215.—Treatment of a Pear tree.—The tree wants root-pruning, root-lifting, or both. Probably there is a tap-root, though this may be diverted by the stone. Do not cut any of the surface or upper roots, but dig down below the tree, and cut off the top or any deep lying ones right through, and lift and relay the upper layer nearer the surface. This should be done in October, just before the leaves fall.—B. C. R.

4188.—Pear for a south-east wall.—One of the best and most useful Pears for this wall would be the Marie Louise. It is a good keeping variety, but the season may be greatly prolonged by making three gatherings of the fruit at intervals of, say, seven or eight days. I think one of the best of all Pears is Doyenné du Comice, but as it will enoced well as a standard it is not worth while to plant it against a wall.—J. D. E.

Plant Marie Louise in November.—E. H.
4200.—Old Vines.—Blight is rather an indefinite term; it may mean anything, and before anyone can prescribe for disease one wants to know the nature of the attack, whether it is mildew, red-spider, scalding, shanking, or any of the other evils to which Vines under glass are subject to when improperly handled. I looked into a viney the other day that I was told had blighted Grapes. In a certain sense

some of the Grapes were blighted, for the berries were, many of them, badly scalded, but the term blight would hardly, in my mind, have suggested scalding. Another case where the Vines were said to be blighted was a bad attack of red-spider. When the Grapes are blighted by mildew there is not a minute to lose if any of the Grapes are to be saved. Sulphur, in some form, is a good remedy for mildew, and whilst using the remedy fight the disease by making the conditions of healthy growth more suitable, rake over the border or borders, and mulch with short stable-manure. The ammonia arising therefrom will be beneficial, but leave a little air on always while the manure is fresh or the ammonia will injure the foliage. This top-dressing of stable-manure is useful, both in cases of mildew and also in red-spider. Scalding is generally caused by not giving air early enough in the morning. Houses fully exposed to sun should have air along the ridge by six o'clock in the morning; the openings to be increased as the sun gains power. It is a good plan also to allow a little more freedom of growth if the Vines have been closely pinched in. Possibly the roots were too dry, and in that case water must be given freely several days in succession.—E. H.

The blight which has appeared on many of the bunches is probably mildew. It is a whitish substance and is very injurious to the Vines, appearing both on the leaves and on the berries, and if not destroyed it will quite spoil the fruit. As a preventive the Vines, after being pruned, should be thoroughly scrubbed and painted over with a mixture of soft-soapy water, a little soot, and thickened with flowers of sulphur. Sulphur applied to the affected part will destroy mildew. It may be dusted on in a dry state, but it makes a sad mess of the berries to dust them over with it. I would try painting the pipes with sulphur, mixed in soft-soapy water. Heat the pipes well so that the fumes of the sulphur may have effect.—J. D. E.

It would have insured your receiving a more satisfactory answer if you had sent some sort of a description of the blight that has attacked your Grapes. It may be mildew or the berries might have been scalded by the overheated air, which it is impossible for anyone to say with such exact particulars. I may, however, tell you that a good many Grapes have gone wrong this season owing to the long drought, and I notice the crops are the worst where the borders have been cropped with flowers or vegetables. Those who failed to

Apple "Lord Suffield."

water their Vine-borders thoroughly in the months of May and June ought not to complain if their Grapes are not in a satisfactory condition, as it is very certain the roots of the Vines required more moisture than they got.

4127.—Pots becoming green.—There is no help for the pots becoming green when the plants growing in them require much water and have to stand in a shady place. Too much water would, of course, induce the green matter to appear, and a stiff soil would only aggravate the evil, but neither are the only causes of the disfigurement of which you complain; it is a combination of circumstances which only altered conditions can change. Certainly pots covered with green will be injurious to many plants.—J. C. C.

All the causes named have some influence, and the water, in some districts, seems to have a tendency to produce this green growth on pots, and also on the surface of the soil in the pots. The plants growing in a damp, shaded house get green sooner than in a greenhouse which is well ventilated. Plants are better in clean pots. It will be better washed off occasionally.—E. H.

4202.—Destroying ants.—I have had no difficulty in getting rid of ants when the position they occupy admits of some petroleum being sprinkled about their runs, but it requires to be done every day for a week. It appears to me that they dislike the smell, and so find out more congenial quarters. Another simple plan is to get two or three saucers and cover the bottoms of them with sweet oil, and place them near their nest. The ants will get in the oil and not be able to get out again.—J. C. C.

4205.—Treatment of a Passion-flower.—You had better take care of the young shoot by securing it to the wall, and at the end of next March move it to the fresh position. Meanwhile prepare the place for it by digging out a hole 18 inches deep and 2 feet over, and as you put the earth back mix some rotten manure with it. The Passion-flower likes a rather light soil, so that if yours is inclined to be heavy you had better mix some lighter earth with it.—J. C. C.

Move the plant at once; there is plenty of time for it to get established before the winter yet. Of course it should be moved with a good ball of soil round the roots. Dig the site up well, adding plenty of sand or road scrapings if the soil is naturally heavy, and see that the drainage is good, but do not use anything in the way of manure beyond a little leaf-mould—it is unnecessary, and, indeed, injurious. This plant grows quite strongly enough when planted out in ordinary garden soil, and manure only renders the growth soft, tender, and flowerless.—B. C. R.

4183.—Pot-root Dahlias.—As soon as the side shoots have grown long enough out them off at a joint, and each cutting should be planted in what gardeners term thumb-pots; they are small in size, but much deeper in proportion to ordinary flower-pots. Place them in a garden hot-bed, which should not be very hot, merely warm enough to throw off a little moisture. Keep the frame rather close, and shade from bright sunshine. The cuttings will soon form roots, and when established in their flower-pots should be repotted into large sixty or small forty-eight sized pots. The plants form nice tubers in these flower-pots; and when the stems decay store them in a dry place for the winter.—J. D. E.

Pot-root Dahlias may be obtained by striking the cuttings in pots at any time from early spring until the end of July. I am engaged at the present time in striking a lot of cuttings obtained from plants growing in the open of sorts that I find do not keep well as ground roots. These are chiefly the White Pompon varieties, such as White Aster and Lady Blanche, which are difficult to keep in any way through the winter, but much better in pots than out of them. The cuttings strike freely now in a cold frame, if kept close and shaded.—J. C. C.

4122.—Bog soil.—This is really peat, or of a peaty nature. If rendered moderately rich by the addition of manure, almost any kind of vegetable can be grown in it with perfect success, and it is excellent for Potatoes, though on such ground they are very liable to disease in a wet season. Lime and kainit (saltpetre) are two of the best fertilisers for such soil, and in growing Potatoes be careful to avoid the too liberal use of farmyard or stable-manure, depending chiefly upon superphosphate of lime for bone-meal and some kind.—B. C. R.

OUTDOOR PLANTS.

BULBOUS FLOWERS.

The bulb octogones are beginning to pour in now, and many readers will be perplexed to know the best kinds to select for giving beauty to the garden in the spring months. The three more important types are the Hyacinth, the Tulip, and the Daffodil.

THE HYACINTH may be grown in three ways—in pots, in glasses, and in the bed or border. It is much grown in glasses for windows and rooms, and the cultural details are very simple. Green glasses are best, and the bulbs look better in them than in receptacles of any other colour. Select good bulbs and let the water only just touch the base, putting a little salt or charcoal in each glass to keep the water clean and pure. Watch to see if a fresh supply is needed, as if it becomes at all foul success cannot be expected, but the water should always be of the same temperature as the house or room. When the glasses are filled put them in a cool, dark cupboard, or even a cellar, for about three or four weeks, until roots have been formed, when remove them to the window so that they can enjoy full light and plenty of air. When grown strongly the growth is vigorous, and the flowers of bright colour. The water will evaporate quickly, and must be replenished. Many seem to think the winter season suitable for putting Hyacinth bulbs in water, but the best month in the year is November, the single varieties being much better than the doubles for growing in glasses. In the culture of bulbs a great fault is not in their actual management, but in late planting. Bulbs got into the ground in September, or October at the latest, always give finer results than when planted later in the year, as the soil in autumn is usually fairly dry, and there is a good season before winter. When delayed later, frosts occur, the ground is wet, and sometimes the festival of Christmas has passed before a start is made. Under these circumstances the spikes and flowers are not satisfactory. All bulbs should be planted thus early, Daffodils in particular, which may be put in at the beginning of September. It is not necessary to have specially prepared soil for the growth of ordinary bulbs; but it is as well, if at all poor, to incorporate with the staple a moderate dressing of well-decayed manure, and the bulbs of the three great classes mentioned may be put about 3 inches under the surface. Clumps of one variety, or several judiciously contrived, are effective, and the Daffodils may be planted freely in the borders, reserving the Tulips and Hyacinths for the beds.

BRILLIANT and varied in colour is the Tulip; and the early single and double varieties are planted more largely than the later-flowering types. The Dutch kinds are thoroughly useful garden flowers, their richness in beds compelling attention. Plant them also in the borders, a few clumps here and there, creating a wealth of colouring. Delightful beds may be composed of Tulips, with a groundwork of Forget-me-nots, Silene, and some other carpeting plant of equal prettiness. One could bring in thus the fine Apennine Wind-flowers where the garden is small, and no woodland walks occur in which to naturalise such spring beauties. As regards cultural directions, follow these given for the Hyacinth. A bed of Double Tulips, carpeted with Pink Silene, Daisy, and White Forget-me-nots, is very charming—a sheet of colouring without garishness. A beautiful and familiar garden Tulip is *T. Gesneriana*, which is the parent of the many fine florists' varieties. Its bold, handsome, scarlet flowers are familiar in old-fashioned gardens, but it is a bulb that should be brought into more use. The bulbs are more expensive than the ordinary kinds. Amongst the species which first are

T. elegans (blood-crimson), *T. Greigi* (the leaves spotted and barred with chocolate, the flowers orange-scarlet), *T. macrosepalii* (carmine), *T. oculis solis*, *T. retroflexa* (yellow), and *T. vitellina* (sulphur white).

DAFFODILS, or *Narcissus*, form a glorious family. A bed of the Yellow "Trumpets" dancing in the breeze is a true spring picture. The Daffodil marks the final departure of winter. One secret of success in the culture of the bulb is to plant early, and once the clumps have got established they may be left alone, although where the culture of the *Narcissus* is made a speciality of they are lifted once every year, and

Rosey Meadow Saffron (*Colchicum autumnale roseum*).

the common kinds every two years. Damp is hurtful, and the soil should be moderately light, selecting, if possible, a south or west aspect. In every garden, however, they will flower well, and all are quite hardy, except in a few instances. As with the Hyacinth, so with the Daffodil. The bulbs may be grown in glasses, but not actually allowed to touch the water. The temperature of the water should be about the same as that of the room; they thrive under very simple conditions, similar to those recommended for the Hyacinths. The bulbs will then flower well. The "Trumpet" varieties, those that partake of the character of the common wilding, the *N. pseudo-Narcissus*, are most suitable for culture in this form. An enthusiast in Daffodils will soon get to know the best varieties, and they include *Empress* (a splendid Daffodil, the flowers large, the broad petals white, and the Trumpet yellow), *Horsfieldi* (the big-flowered lorifolius *Empress*, bright yellow), *maxims* (rich yellow, almost orange, a beautiful variety), *princeps*, *Barri* (conspicuous yellow, with scarlet eye), the double *Orange Phoenix*, or *EGGS* and *Bacon* (white and orange), *Sir Watkin* (the yellow flowers of great width), *Jonquils*, positions *ornatus*, and the common *Poot's* Daffodils. The bulbs may be put about 4 inches under the soil, and when to be lifted this should be done after the leafage has died down. It is a bad plan to disturb them while the foliage is still green, or to twist their leaves into a knot. What a wealth and beauty there is in bulbous flowers! Take

THE CROCUSES, and see the rich varieties of colours supplied by the many forms. Every one is familiar with the common blue, yellow, and white Crocuses that form broad lines to the beds in the London parks, and provide amusement for the mischievous sparrows, never so happy as when pecking the dainty petals. But besides the spring-blooming kinds we have a rich autumn gem called *C. speciosus*, rich blue, barred with purple, the stigma deep orange. A clump of this on a late September day is delightful, and yet it may be accounted a rarity, although useful when out. The autumn *Crocus* are quite as easy to grow as those proper to the season of spring, whilst acquaintance with them will whet the appetite for the Meadow Saffrons (see illustration), a very beautiful class of autumn-flowering bulbs. The common Meadow Saffron (*Colchicum autumnale*) that yields the famous drug, is a lovely garden bulb, purple-rose being the colour of its flowers, whilst there are several forms of it, as a *plum* (pure

white), *fl. album-plenum* (double white), and *fl. roseum-plenum* (rose-purple), the flowers of very large size. *Colchicums* must not be exposed to the full influence of the weather, and the reason is obvious. Amongst Grass they look extremely pretty, and receive in a measure shelter from the hoary reins of late autumn. A sweet gem of the early spring is the *Netted Iris*. Other *Iris*es flower early in the year, and are each attractive, but *I. reticulata* bears away the palm. I remember once visiting the gardens of Lord Suffield, at Cromer, where the bulb was established in the woodland. The flowers have a distinct Violet fragrance, a few plants in a pot accenting a large conservatory. Moderately light soil and a sheltered situation are suitable, the flowers appearing about March. During recent years more favour has been shown to the English and Spanish *Iris*es, which bear their bold, beautifully-coloured flowers in the early autumn. The so-called English *Iris* is *I. anglica*, but it is really a native of Spain, the reason of its popular title being that bulbs of it were brought from England to Holland, and the impression of the Dutch was that it was a native of Britain. These *Iris*es are hardy, robust in growth, attaining a height of from 1½ feet to 2 feet, the broad handsome flowers displaying a border of purple, violet, blue, and lilac. We owe many of the finest novelties to the Dutch, who have done much good work in producing splendid bulbous flowers. Plant the bulbs early in the autumn, not closer than at a distance of 6 inches apart, and put them at a depth of 3 inches. A good growth results in ordinary soil, and they are not averse to life in the suburbs. A delightful companion to the English *Iris* is *I. hispanica*, which is known, and appropriately, too, as the Spanish *Iris*, or *Flag*. It blooms shortly before the English kind, and the flowers are smaller, without that broad, massive appearance characteristic of *I. anglica*. Both thrive under the same treatment, and we get a great range of colours, from pure white to clouded orange, dusky browns, shot with other hues, a curious assortment of varied tones. Perhaps the white or yellow flowers are the most striking, and if only two varieties are grown, select those of that character. Who does not know the familiar old

CROWN IMPERIAL? It has many varieties, and all are hardy, bloom in the spring, and grow in ordinary garden soil. The writer has seen the yellow kind, named *intea*, in a little back garden not far removed from the busy Loudon metropolis. Put the bulbs about 3 inches deep, and leave them alone to grow into bold, telling, picturesque clumps. Fourteen varieties were counted in one catalogue, but really only the common kinds, *aurora* (red), *lutea* (yellow), and *Slagwasard* (a delightful shade of red), need be considered.

THE GLADIOLUS is a glorious bulb or corm, as it is correctly called, and there are a great many varieties, hybrids, and species. Few plants of the present day are in greater favour, or have been more hybridised to gain new kinds. *M. Lemoine*, the celebrated French florist, has, through his zeal in crossing one species with another, inaugurated new sections, as *Nancianus*, *Lemoinei*, &c., all playing a good part in the decoration of the border. Care is necessary in embarking in Gladiolus culture. The many splendid varieties that attract the eye at exhibitions are not always the most tractable in the garden, but general rules can be laid down for cultivation. *G. gandavensis* represents a splendid section, and then there are earlier blooming varieties, as *G. Colvillii*, *G. ramosus*, and others, all possessed of distinct beauty. Clumps of Gladioli between Herbaceous *Phloxes* look well, and the soil should be fairly light, with a moderate quantity of manure mixed with the staple. Damp or stagnation about the roots results in almost total failure. Success can never be looked for under such circumstances. Put the bulbs 4 inches in depth, and half a foot apart, March being a good month for planting, bulbs put in during April carrying on the succession of bloom until later in the autumn. Even as late as June they may be put in to provide a continuance of gay flowers. The hardest of the Gladioli are the Hybrids of *G. Lemoinei*, which are very easy to grow, thriving where the other varieties fail utterly. A splendid kind for colour is *G. brenohlyensis*, the flowers rich-crimson; but in the many Hybrids of *Gandavensis* there are exquisite

shades of colour, distributed in bars, stripes, and delightful mottlings on a pure-white ground, sometimes touched with rose. Begin cautiously at first, and see if the *Gladiolus* relishes the situation, soil, and surroundings of the garden. If this is fortunately the case the corns may be planted with a bolder hand. *Bahianas*, *Ixias*, *Sparaxis*, and *Tritonias* are not bulbs for the average garden. They require much attention, and need especially warm situations; but a few clumps of *Cyclamen europæum*, the little hardy, autumn-flowering "Sow breed," seem to bring a gleam of sunshine to the rocky or border in late autumn.

GEMS amongst spring-flowering bulbs are the *Chionodoxas*, and the two best are *C. Luciline*, appropriately named the *Glory of the Snow*, and *C. sardensis*. The *Glory of the Snow* is such a weed that it will sow itself and prove almost a plague, if such a delightful starry-blue flower can be thus described. *Sardensis* has much deeper coloured flowers, and is not quite so free in bloom. A stately September-flowering bulb is *Hyacinthus* or *Galtonia candicans*, a native of the Cape, sending up in the autumn sturdy spikes to a height of over 4 feet, the bell-shaped blossoms pendent, like the nodding *Snowflake*, appearing at intervals on the vigorous scape. If there is space for a group of hardy *Fuchsias* plant the *Galtonia* amongst the shrubs, as the white flowers and pendent scarlet strings of blossoms on the *Fuchsias* are in rich contrast. Nor would the garden be in any sense complete without the old-fashioned *Allium Moly*, living in the poorest soils, and making gay patches with its yellow flowers. A shady moist corner may be reserved for the *Lily of the Valley*, the *Dog's-tooth Violet*, *Erythronium americanum*, and the many beautiful varieties of the common *E. dens-canina*, the nodding *Snowdrops*, the summer *Snowflake*, *Lewcojum aestivum*, and its relative *L. vernum* (that as its name suggests blooms in the spring), the *Muscari* or *Grape Hyacinths* (rich blue of various shades), the old *Star of Bethlehem*, also *Ranunculuses*, and, for a sunny border, where the soil is light and warm, the *Swamp Lily* (*Zephyranthes caudata*).

C. T.

ORANGE STONECROP (SEDUM KAMTSCHATICUM).

This is a beautiful broad-leaved prostrate species (see illustration), not unlike *S. spurium* in habit, but distinguishable from it by dark orange-yellow blossoms. It flowers profusely in summer, and is quite hardy in almost any soil, but it succeeds best in a warm, rich loam. All lovers of the beautiful *Stenocrops* should certainly add this species to their collection.

4184. — **Shamrock.** — The best treatment is to plunge the pot out in the open air, either in the border or in ashes or Coco-nut-fibre. The plant is quite hardy. — E. H.

4196. — **Sowing down a lawn.** — Better sow the seed at once. The ground is moist now, and the seed will soon germinate and grow very fast. Of course, the turf will not be very strong this year, but it will have got a start, and there will be a beautiful sward next spring. — B. C. R.

— Apply a rich top-dressing and sow the seeds at the beginning of September. — E. H.

4212. — **Artificial manure for a garden.** — The manure should have been applied when the Potatoes were planted, or before. It is a great mistake to manure the ground for Winter Greens heavily, as the plants then make a too rank and sappy growth, and fall a prey to the first sharp frost, but if manured for the previous crop it will be just right for them. The last fertilizer that can be applied now is soot (if the land were light a little salt might be added), with some wood-ashes or burnt soil. Jost hoe or fork it lightly into the surface, put in the plants, and make all quite firm round their roots. If the soil is very poor, a light sprinkling of good guano, or of Thomson's Vine-manure, might be added, just to give the plants a start, but anything like luxuriant growth is detrimental, and must be avoided. — B. C. R.

— I should make a dressing of soot do for the green crops this autumn. A good high quart of soot to every square yard of ground spread on the surface and forked in is the best way to apply it. For the spring and summer you cannot do better than use the English Guano. It is a capital fertilizer, and its properties are not quickly exhausted. It can also be obtained at

a reasonable price, and instructions as to quantities are sent with it, which I have found to be quite reliable. — J. C. C.

4204. — **Treatment of Carnations.** — If the plants are old and straggling layer some of the shoots at once, and make a fresh plantation in September. If close and tufted, as the old *Clove* is on some soils, the plants may be left undisturbed for several years. *Carnation Grenadin* is a selected type that comes very fine from seed, and is easily raised. It is too late to sow now with any prospects of bloom next year. Sow next spring, and plenty of plants will be obtained for another year. — A. H.

— The old *Clove* and *Grenadin* are both best propagated by layers. If the plants have been one year only potted, it is a good plan to leave a few layers around the old plant to flower next year. The surplus layers can be removed and planted somewhere else, but to do the *Carnation* well it requires rich, deep soil to grow in, and when this has been well-manured the plants will do two years in succession on the same ground, but it is necessary to give them a surface-dressing with some rich material in May. — J. D. E.

— By all means layer the plants annually, and this should be done at once — the sooner the better. You may either lift the rooted layers and replant them in the autumn, or if you prefer large dense masses let them remain and flower where they are. If the shoots of the plant of "Grenadin" are not strong enough to layer, take them off with a sharp knife and insert them as cuttings; they will root fast enough in light sandy soil under a handlight, kept moist (not wet), and lightly shaded. I should say that a little variety in the way of a few plants of the *White Clove* (*Cloire de Nancy*), or *Mrs. Muir*, *Raby*, *Mrs. R. Hole*, &c, intermixed with the others, would be highly advisable. — B. C. R.

4124. — **Management of a garden.** — First, as regards the north wall, or border, which you say is sheltered. If so, you must not expect great things from plants put in there. I should plant *Ivies* for climbers, and none is better than *canariensis* or *Emerald Gem*, a very quick-growing kind with abundance of glossy green leaves, or you can have also such kinds as *Lee's Silver*, if you wish for a variegated form. In the border plant *Lilies of the Valley*, the graceful *Solomon's Seal*, *Spanish Squills*, very charming in the spring; there are white, blue, and rose-coloured varieties. Ferns would succeed well, and there is a wealth of fine hardy kinds. The beautiful *Funkias*, or *Plantain Lilies*, as they are also called, *Lilies*, the *Mossy Saxifrage*, and the *London Pride*, *Creeping Jenny*, and such

or we may say early, but early in autumn they may be put in, also a number of bulbs, such as *Daffodils*. You should devote your energies now to getting the soil into proper order. If very heavy, lighten it by the addition of lime, in which small gardenes are usually very deficient, or any light soil from some neighbouring place, which you may possibly get very cheap. The position in the fall and is better adapted for hardy flowers, and you will be able to have a few *Roses*. General *Jacqueminot*, *Baroness Rothschild*, and *Mme. Gabrielle Luizet* will succeed well. These must be planted in the autumn, say October, in a good loamy rich soil, otherwise the growth will not be very satisfactory. *Roses* need a liberal diet. Get bush plants, not standards. The reason, doubtless, for the *Clematis* appearing in ill health is through a too dry or poor soil. It is most likely that the recent hot weather has effected it severely. If you wish to make the garden gay at once, plant *Zonal Pelargoniums*, *Tuberosa Begonias*, or such like bedders, but you cannot get much effect this year, the time is too short. Prepare for next year, and with a judicious selection of things the garden may be made bright with colour. Get in bulbs, such as *Daffodils*, *Hyacinths*, *Tulips*, and the *Crocus*, also such pretty little things as the *Glory of the Snow*. Sow a few annuals, *Sweet Peas*, *Sunflowers*, being important; then you can plant in the autumn *Hollyhocks*, *Careations*, and *Pinks*, and in the spring *Tufted Pansies*, which are really the most useful things one can have in a garden. Read carefully my note in *GARDENING* on "A house border" (No. 750, July 22, p. 287). A carefully compiled list of things is given there, which are also suitable in your case. — C. T.

4124. — **Dandelions on a lawn.** — The best way to eradicate the roots of these, as well as *Plantains* on a lawn, is to cut them off with a sharp old knife, and then pierce the root with an iron skewer or bennet pin dipped in carbolic acid. This effectually prevents another start, and it is not an expensive process like pouring the acid on each plant, for a single bottle will last a long time if merely used as a dipper for the skewer. If the *Dandelions* are very numerous the Grass will look rather bare when they are taken out; the best remedy for this is to sprinkle the lawn with a mixture of fine soil and soot in equal quantities, only just enough to darken the Grass, not to cover it up. This washing down to the roots with the rain will so nourish and thicken the Grass that it will soon cover up the bare spots from which weeds have been exterminated entirely. — I. L. R.

4116. — **New Zealand Flax.** — This handsome plant flowers well in the south of England, except after a hard winter. A group of New

OUR READERS' ILLUSTRATIONS: *Sedum kamtschaticum*. Engraved for *GARDENING ILLUSTRATED* from a photograph sent by Miss Emma Wolley Dod, Edge Hall, Malpas, Cheshire.

things as the *Monkey-flowers*, which also like a fair amount of moisture. With a good selection of these you will get a rich variety of colours, ranging through many shades, some finely spotted. It is very late to plant things now,

Zeeland Flax, which stands in the garden in Devonshire, which the writer had had for the last six years, has flowered well three times during that period; three years ago it also flowered. It is very late to plant things now,

handsome spikes of bloom which it threw up. This was, however, after a specially mild winter; severe and long continued frost and snow, such as we have had, with hizzards, for the last two years, appeared to check it considerably, and no flower appeared after these seasons. During the Jubilee summer, which was very hot, the plant flowered well; also the following season, so that it appears that it is only necessary for it to receive sufficient warmth to flower each year in the south of England.—I. L. R.

INDOOR PLANTS.

FREESIAS.

This is the best time to pot these beautiful flowers, and although they are by no means difficult to cultivate, a good many fail to get them to flower satisfactorily. As these plants are so extremely popular a brief note on the way to manage them may be of service to those who have hitherto not been successful. The first thing is to produce good strong flowering bulbs; they are not large even at the best, but unless of the size of ordinary Snowdrop bulbs they will not flower. Five or six-inch pots suit them well, and the soil they do well in is rotten turf, broken up fine, and a little leaf-mould, and peat-soil, with sharp silver sand; crook the pots in the usual manner, and fill about three parts full of soil, pressed down firm, and on this place about six or eight bulbs, covering with soil, and set them in a cold frame. Do not give much water until they commence to push the foliage well above ground. They require an intermediate temperature, if it is desired to get them into bloom early in the new year; but if required for spring a shalf in the cool-house suits well, and when pushing up their flower-spikes, a little weak liquid-manure helps them greatly. After they cease flowering, and the foliage shows signs of changing colour, reduce the quantity of water at the root until they can be dried off and rested. J. G. H.

RAISING SEEDLINGS.

The experience of "Mr. W. Cotton," as given in GARDENING, no p. 269, is eminently gratifying and encouraging, and will no doubt induce many others to "go and do likewise," or try to do so. I have always been a strong advocate for growing Pelargoniums and many other plants from carefully-saved seed in preference to stocking a large number of costly "named varieties," and there is nothing more fascinating than thus to raise seedlings and watch the flowers expand one by one. But I should like to remind "Mr. Cotton," and all whom it may concern, that such an occurrence as he describes is by no means common, and indeed is an extremely "lucky hit." He may try again a hundred or a thousand times and not be so successful. That four seeds only (and self or chance-fertilised ones, too) should have produced four first-rate and different varieties, is little short of marvellous. I have raised some pretty good Zonals myself, but I may mention, as a contrast, that during the last three or four years I have raised and bloomed hundreds of seedlings from the very best named sorts, all carefully fertilised, and though I have obtained several very good and pretty flowers, there have not, so far, been six out of the lot efficiently distinct and superior in character to be worth sending out as "named varieties." There is more "luck" in this kind of thing than anything else, though skill and perseverance, of course, count for a great deal. B. C. R.

4192.—Sensitive plant.—They are not more difficult to grow than other warm greenhouse annuals; they are raised from seeds in spring, started and grown on for a time in peat, then moved to the greenhouse for the summer. They are generally treated as annuals, though they may be kept through the winter in a warm-house. The Sensitive plant (*Mimosa sensitiva*), is a native of Brasil, so must have warmth in winter.—E. H.

—These plants may be grown on a second year or more, but I find they do best treated as annuals. Sow the seed early in the year in a hot-house, and as the plants increase in size pot

them on, and they will flower well in 5-inch flower-pots. The leaves drop off in winter, and the plants should be kept rather dry at the roots, and in a temperature of 50 degs. to 55 degs.—J. D. E.

4190.—Camellia cuttings.—Place the plant in a 3-inch pot, draining it well, and using a light mixture of peat and sand in equal parts, with a little leaf-mould, or equal parts of loam, Cocoa-nut-fibre, leaf-mould, and sand will do almost as well. If possible, plunge the pot in a gentle hot-bed, but in any case keep it close, moist, and shaded until rooted out and forming again. I have never struck cuttings in this way, but I do not see why they should die if you can get the roots to lay hold of some sweet, sandy soil before they run too far. The sooner the cutting is potted now the better.—B. C. R.

—The sudden change of taking the rooted plant from the water and planting it in soil would be the cause of many of the young plants dying, especially if care is not taken to preserve the young roots. Every plant might be preserved if taken out of the water and carefully potted in sandy peat soil. Give a good watering overhead from the fine rose of a water-pot, and place a bell-glass over the young plant to retain moisture about it until the roots have taken hold of the soil. The bell-glass should be removed daily and wiped dry.—J. D. E.

—Cuttings rooted in water are rather more difficult to establish in soil than when rooted in soil, as roots made in water are always more or less delicate. Still, with careful watering, there should not be many losses.—E. H.

4109.—Potting Cacti.—Now is the best time to repot them, providing the roots have well filled the ones they are now in; hot do not repot if unnecessary, as they will grow to a large size in very small pots. This summer has been very good for growing out-of-doors, my garden being unusually dry and hot. Drought and heat they enjoy, being mostly natives of the hot parched plains and slopes of Mexico. I have several of mine out-of-doors, but move them in by September.—E. J. YOKES, *Kingsworthy*.

4171.—Double Begonia buds.—"T. S." complains of the buds of his double Begonias dropping. I can quite sympathise with him as to double Begonias under glass. They drop cruelly and disappointingly. I have been told in GARDENING that it was a matter of ventilation, but I have not found any amount of ventilation prevent it, and some Begonias are capricious. I have a beautiful double crimson. It opened its first hatch of buds well, and held the flowers for a good time. Since then it has dropped every one. I have tried one expedient which I think has been tolerably successful. I have nipped off all the single buds as soon as they appear. The plant does not look so handsome as when the blooms are in clusters, but the double ones under this system, I find, generally remain on and open. Single Begonias do not seem to be addicted to this vice of bud-dropping, and therefore seem best adapted for amateur cultivation.—CENTLEMAN.

4210.—Heating a small greenhouse.—The wash-house will be a capital place for the boiler; the coil is small, but if properly set ought to afford sufficient heat. I have never constructed a furnace on the plan suggested by "G. H. W.," and should not like to say how it would answer. If I were doing the job I should put in one with an ash-pit (9 inches deep) and five bars, in the ordinary way, placing the lowest tube of coil 6 inches above the bars, and enclosing it in a circular tapering furnace 1½ inches larger than the coil all round. Exit into chimney to be a clear course above the highest tube of coil; this course being brought in well so as to keep the pipe itself out of the direct draught into chimney, which would soon burn it through. A tight-fitting door should be fitted to ash-pit, with a draught regulator, so that when once going the draught could be almost stopped. This is the best "slow-combustion" principle.—B. C. R.

4199.—Treatment of bulbs.—White Lilies, Snowdrops, Daffodils, and Crocuses will do for a considerable time without transplanting. Still, they are better lifted occasionally for the purpose of thinning the bulbs. For planting in beds in connection with bedding plants, Crocuses, Hyacinths, Blue Squills, Snowdrops, and Tulips, are suitable. In some instances the

planting of the summer bedders may have to be delayed till the end of May or beginning of June. The bulbs, under careful management, may be used year after year. It is best, if possible, to leave them undisturbed till the growth is nearly completed, and then move elsewhere to ripen, keeping them occasionally watered till the growth dies away gradually. The increase or deterioration is pretty much a matter of management, but it is important with early-flowering bulbs, such as Snowdrops, Crocuses, and Squills, that they do not get out of the ground too long in autumn. This is one cause why they make a poor show in spring. October is quite late enough to plant.—E. H.

—Most bulbs do best undisturbed in the ground year after year. They should, of course, be planted in the first place in good soil well worked, and manure placed underneath them, away from the bulbs, but so as the roots can easily reach it. Some bulbs are injured by the manure coming into contact with them. The most popular and beautiful of the spring-flowering bulbs are the Crocuses, Scillas, Snowdrops, Iris reticulata, Chionodoxa Lucilla, and C. ardensis (the Glory of the Snow); the plants flower amongst the melting snow of their native habitats, Leucojum verum. Most of the Lilies should become established. Fritillaria, Crown Imperials, Colchicums, Narcissus in great variety, &c. The bulbs usually planted out in the autumn and removed in the spring to make way for the bedding plants are Hyacinths and Tulips.—J. D. E.

—Your question necessitates a rather lengthy answer. The best season for planting bulbs is, taking them generally, the autumn, and as early as possible. As you appear to be going in rather strongly for bulbous flowers bear this in mind, many failures in their culture occurring through delaying the planting until the verge of winter, and they have to be put in under disadvantageous circumstances. I give here a few general rules about bulb culture. In the first place the soil must be well prepared, not too heavy, and the bulbs just, as a rule, about 3 inches below the soil, the smaller bulbs at a shorter distance than those of larger size. The Daffodil is an important subject. You can get a rich variety of kinds, and I should select the following twelve kinds to commence with—you can add others as your love for them increases: Emperor, Empress, or Hornfield; postious, better known as the Phoenix's-eye, the most useful form of which is ornatus, and the double white, a beautiful Gardenia-like flower, Stella. The Orange Phoenix and Tolomanus plena, two good double kinds; the charming little N. nanus, the Yellow Hoop Petticoat, N. conspicuus, Sir Watkin, Queen Ann's Double Jonquil, and regulous. This small list comprises varieties of very different character, embracing the finest Trumpet and Poets' kinds. As regards their after treatment, you must let the foliage ripen off naturally as far as possible, and lift the bulbs, thoroughly drying them in the sun before storing. They may be stored in a cool place out of the reach of frosts, and replanted again in the following autumn, commencing first with the Poets' kinds. The bulbs will produce offsets, which will provide new stock, and the old ones will last some time. If you like, you may leave the bulbs in the ground for two years, but certainly not longer. The great bulb growers lift the major portion of their stock each year. I ought also to have mentioned that bulbs, as a rule, are much averse to damp, and, therefore, if your garden is wet and low-lying, raise the beds in which the bulbs are planted above the usual level, so as to let superfluous moisture drain away. So much for the Daffodils. Now a word as to the Tulips. You should have a few of the ordinary Dutch varieties, which bloom early, and are very bright and showy. Give them similar culture to the Daffodils, but I should also get a few of the later flowering kinds. Possibly you will not care to spend much in these, but such kinds as T. fulgens (splendid crimson), a tall, fine Tulip, T. macropisella (carmine-rose), and T. epistulata (rich orange) are well worthy growing for their noble flowers. Plant them, as we should all bulbs, in good clumps, as then a rich effect is got. Hyacinths need also similar treatment, and you can purchase these cheaply in mixture. Crocuses and the Chionodoxas must also be included. The latter are very

charming, and as easy to grow as almost any bulb. Get first *C. Lucilla*, which in time will prove almost a weed. It has blue flowers, produced very freely in racemes, and either on the rocky or in the border it is pretty. *C. cardensis* has dark-blue flowers, and is very handsome. These you can allow to remain in the ground. The common *Star of Bethlehem*, another spring-flowering bulb, is not to be despised. I had a border of it this year, which was extremely pretty. The bulbs are not dear, and the flowers are pleasing, although unfortunately they only open in the full sun. There is a small selection, but you will find a wealth of beauty in the various kinds, and all are easy to grow.—C. T.

TREES AND SHRUBS.

TREE PEONIES.

The selection of the best spot in the open garden for a Tree Peony (see illustration) is a matter of more importance than any subsequent attention which it requires. It must have an open spot away from the shade or shelter of trees; but, if possible, it should be sheltered from north and east winds, which, as a rule, prevail in spring, about the time when the plant is pushing out its new growths. It should be the aim of the cultivator to retard the growth as much as he can, and if the locality is

acting effect, inasmuch as the young wood did not ripen, through want of sufficient sunshine. As to position, it is generally admitted that Peonies look best when isolated on a lawn, not far away from a shrubbery or a group of some sort, but so situated that they appear to have some connection with one or the other, as the case may be. Being deciduous, a spot should be chosen for them where they would be backed up by Evergreens for the sake of the winter effect. G.

4196.—Cutting *Laurustinus*.—The best time to prune or cut back this plant is in the spring, after the flowers are over; then it starts into growth again directly, and flowers are produced more or less the following winter. It is rather late now, but after this rain a fresh growth would soon be made, and if done at once there would be a decidedly better prospect of plenty of bloom the winter after next than if left until next spring.—B. C. R.

—Cut the *Laurustinus* hedge after blooming is chiefly over in spring—say, in March.—E. H.

4189.—Propagating Birch, &c.—The common Birch is propagated from seed sown in the open ground. The seed ripens in September, and should be gathered and dried. Keep it in a dry place and sow it in beds in March. Sandy soil seems to suit the Birch best, and the beds should be made level, sowing the seed thinly

in the temperate-house at Kew, where some good bushes were planted out in the beds. The form of *Kerria* in general cultivation—viz., that which bears throughout the summer great numbers of deep golden-yellow flowers like small double *Roses* is really handsome, and despite the frequency with which it occurs in some places, it is in others a neglected shrub.—T.

Spiraea palmata.—One of the best dwarf shrubs comparatively in beauty now is this *Spiraea*, which makes a glow of colour in the garden with its beautiful rosy-crimson flowers. It is unfortunately not much grown, although bright and handsome, and in ordinary soil succeeds well. One usually finds that by the side of a stream or pond the growth is unusually robust, and in such a position the masses of flowers are most telling. One reason of its supposed tenderness is its culture so largely in pots; but the plant is quite hardy, liking best a well-drained soil. Always contrive to get a spreading mass, as the effect is much richer. There is a white variety, similar to the type, and named *alba*. The flowers are creamy-white instead of rose-crimson, and elegant in pink; but the typical kind, the crimson-flowered kind, is the most useful and effective.—V. C.

ORCHIDS.

ODONTOGLOSSUM WILCKEANUM

PALLENS.

The flower "S. J." sends, and which he calls the tree crispum, is not that species at all, but it is what I take to be the kind named above. Why this plant required a distinctive name is more than I can understand. *Wilckeanum* is a supposed natural hybrid between *O. crispum* and *O. luteo-purpureum*, and it was first introduced by the Messrs. Low, of Clepton, about fifteen years ago, and it has frequently been imported since in the original plant. The flowers of a good variety are between 3 inches and 4 inches across. The sepals and petals are broad, the latter broader, the ground colour being pale-yellow, more or less marked with chestnut-brown; but in the variety now before me, having a ground colour of French white, variously spotted and blotched with chestnut; this is one of the very best of the natural hybrids, being of good strong growth, which sends up a spike of good flowers, and you may well be proud of it; but you may rest assured that this is the name of the variety you send. The plant thrives well with those of *O. crispum*, *O. Hilli*, and various others, and you in all probability received it intermixed with plants of *O. crispum* and *O. luteo-purpureum*. I do not think it is necessary to say more of this variety now. I have some recollections of saying something of it before in a previous number of GARDENING, and I do not wish to occupy the space with repetitions, but you have a most excellent form of this so-called hybrid. MATT. BRAMBLE.

Tree Peony in flower in Scotland.

naturally warm, the Tree Peony will require particular attention, otherwise a sharp frost in April will destroy both growth and bloom. It is the practice in many places, and a very good one, to protect the plants by a movable glass light, or by fitting up around them a temporary framework on which is placed muslin, canvas, or other thin protecting material during the most critical time, that is, from the time when the young shoots begin to lengthen till all fear of frosts is over. If a plant is overtaken by frost, without protection, then the best thing to do is to screen it at once from the morning sun, so that the plant may thaw gradually. In some districts no protection is necessary, and this is the case principally in inland gardens, which are colder than those in the valleys, and therefore vegetation does not start so early. In old days when Tree Peonies were as much thought of as *Cattleyas* are now, all manner of devices were resorted to in order to tide the plants safely over our treacherous springs, for it was found that scarcely any amount of cold during the dead of winter harmed them. In many parts of the country, indeed, they were unscathed through the terrible winter of 1837 and 1838. Some hygone Peony growers used to plant on the north side of hills, so as to retard growth, but such situations had a counter-

over it. Cover very slightly indeed, and tread the ground firmly, merely levelling it with the back of a rake. When the young plants are a year old transplant them. There are numerous choice varieties of the Birch, which must be propagated by budding or grafting on seedling plants of the common variety.—J. D. E.

—The Common Birch is raised from seeds, and the weeping varieties by grafting on the common variety. All trees which produce seeds are best obtained from them. To this class belong the Hazel, Beech, Sycamore, Ash, Chestnut, &c. Birches are usually layered, and this method of propagation is suitable for many trees where cuttings are difficult to strike.—E. H.

Variegated-leaved Kerria.—This form of the old *Kerria japonica* has the leaves variegated with pure white, and it can with confidence be recommended to those fond of variegated-leaved shrubs, as the marking is clear and distinct, while the light coloured portion does not become at all disfigured by exposure to the summer's sun. Like the ordinary form, its flowering season extends over a lengthened period, but the blossoms are single, and not double, as in the *Kerria* that is usually seen. The golden-coloured flowers nestling among the variegated foliage has an uncommon and at the same time very pretty effect. It is quite hardy, and succeeds well in light, warm soils. Under glass, too, it is very useful, and in this way it is prized for many years a very attractive feature

MILTONIA WARSZCZICZI.

I AM asked by "G. Lambert" to tell him the name of the flower which he sends, and to say something of its native country and the best method of cultivating it? The first portion of this request he will see stand at the head of the article, which may not accord with the name he has it under. This plant would appear to have been first found some sixty years ago; but it was not until about forty years back that it was named by Reichenbach after the collector to whom it stands dedicated, and it was not until the year 1868 that it was introduced in a living state, when I saw it with Mr. B. S. Williams in a living state, and in the following year, being in Germany and coming down through Belgium, I saw it again with M. Linden at Brussels. Reichenbach would appear to have been misled with some of the varieties, for he named in 1863 *Onocidium fuscum*, and as a decided mark of the favour in which it was held it was also known in many gardens by the name of *Odonoglossum Weltoni*. It is an erect-growing, but dwarf, evergreen plant, the bulbs being compressed and sharp at the edges, and each bearing a single leaf. The plant, when well grown, attains to a height of about a foot, and it is of a light, pleasing green colour; the spike grows to some 15 inches or 18 inches, very often if simple it bears many flowers, and these are set somewhat closely; but when it becomes

paniculate it bears many flowers. The sepals and petals are somewhat similar in both shape and colour, being undulate on the edges, sometimes reddish-brown with a white tip; at other times they are of a good full yellow, the extreme tip being recurved in most instances. The large lip is somewhat orbicular and deeply bilobed, the central part purplish, having a patch about the centre, as if newly varnished. Beyond this is a zone of rose-lilac, and beyond this is an outer marginal border of white. These beautiful flowers vary considerably in the brilliancy of their colours in the different varieties, but all last long in full beauty. My first acquaintance with this plant was in Mr. Williams' establishment, and he told me that the collector that sent it to him said he found it at a greater altitude than that at which he found *Odontoglossum Alexandrie*, so that I tried my plants in the same house with them; but they did not do well here in the winter months, and I removed them to a warmer position, giving them a heat of about 55 degs. at the lowest, and keeping them very evenly moist, and in this temperature the plants rapidly improved. And so I would advise my enquiring friend, "O. L.," to do. He may remove the plant to the warm end of the *Odontoglossum* house in the summer time, when it likes an abundance of water and plenty of moisture in the atmosphere, and this may be given with impunity if the drainage is perfect and in good working order, and it likes to be potted in good peat fibre and Sphagnum Moss. It enjoys a good exposure to the light, but do not allow the sun to shine upon it during the hottest part of the day, but provide a light shading to be drawn over it at this time.

MATT. BRAMBLE.

SACCOLABIUMS AMPULLACEUM AND CURVIFOLIUM.

I AM asked by a friend, signing himself "An Orchid Learner and Lover," if these two names do not represent one plant? Now, these two *Saccolabiums* are quite distinct plants, though they belong to the same section, and resemble each other inasmuch as they both have richly coloured flowers, borne on upright spikes; but here all resemblance ends, and if my friend has seen, as he says, "two Orchids bearing these names, but could not see any difference in the plants, never having seen either flower," then I would say that it is two names given to one plant, but which I cannot say; but I hope that after reading this article he will be able to determine which is which. *S. ampullaceum* is a neat Orchid that was known in the early days of the century; but I think we are indebted for it in a living state to my old friend Gibson, whom I frequently visited when he was in charge of Battersea-park. Well, he was collecting for the Duke of Devonshire in Northern India in 1837, and sent some plants home to Chataworth from the Khasia Hills, and this was the first time I think it was seen alive in our gardens. There was no means of getting the plants down by rail then, there were no fast ocean steamers, and no Suez Canal to slip through in those days, but all the plants that were sent home had to come round the Cape of Good Hope in sailing ships, so that they required good packing. The Messrs. Low, of Clapton, imported this plant in considerable numbers, and the Messrs. Rolleston, then having a fine nursery at Tooting some twenty years ago, introduced a magnificent form of it from Burmah, which was called *Moulmeinensis*, which was much stronger in its growth, and which made a taller spike with larger and brighter flowers, but the normal plant has short and straight ligulate leaves, which are truncate at the ends, somewhat thin, and pale-green, the spike is erect, shorter than the leaves, the flowers being set close together and of a pure rose colour, and these will last in full beauty for a fortnight or three weeks, but it is not well to allow them to remain upon the plants as long as they would do. *S. curvifolium* is a very different plant, having leaves crowded, thick, and coriaceous in texture, with sharp-pointed ends; the spikes are erect, and they bear a dense raceme, which is 6 inches or 8 inches in length, the flowers being of a bright cinnabar-red, with a bright orange-red to the spur of the lip. Now both these plants like to have their roots free in the air, and they will thrive best in a hanging position near the light

and they should be suspended in small Teak-wood baskets, well-drained, and for soil use simply fresh Sphagnum Moss. The temperature of the East Indian Houses is requisite for them, and a nice moist atmosphere. Of course, shading will be provided for these plants when the sun is too powerful.

MATT. BRAMBLE.

LILIUM CANDIDUM.

THIS lovely Lily, where it does succeed well, is one of the finest hardy plants in cultivation; but, unfortunately, no amount of coaxing will cause it to flourish in some places. As it succeeds well here, I will briefly describe the kind of soil and mode of culture, in the hope that some may be enabled to grow it who have hitherto failed. Our soil is a rather light loam, resting on gravel, and I think that abundant drainage is necessary, as I find fine clumps of this Lily in the most robust health in cottage gardens close by, where the soil is very shallow and poor. This season being very hot and dry,

Flowers of Madonna Lily (*L. candidum*).

Lilium candidum, in common with other hardy flowers, was in full bloom quite early in June, considerably in advance of its usual date, as all the blooms not cut had dropped before July 1st. But the crop of bloom did not suffer from the drought like many other flowers, as after the flower-spikes are formed, and the buds fairly well developed, the blooms will open without any help from the roots at all, if placed in water, or even placed in any damp place, and I cut a great many of my finest spikes before a single bloom is expanded, for if intended to be forwarded any distance, it is much easier to send them in closed up bud state, and they will expand beautifully in water. Various opinions prevail as to transplanting, but I find the finest spikes come from beds the second and third year after transplanting, and I seldom let any stand longer than four years in one place. Shelter from rough wind is desirable, but not shade, except for the purpose of retarding a portion of the stock, which, whether grown for private supply or for market sale, is one of the best flowers that can be grown. It forces well.

JAMES GROOM, Clapton.

FERNS.

MAIDEN-HAIR FERNS FOR CUTTING.

WHERE there is any great demand for out fronds of these Ferns, the earlier started plants will no doubt have been run upon somewhat hard from the time their fronds were fit for use. It will do these plants a considerable amount of good if they are for a few weeks kept quite cool and comparatively dry at the root, only just sufficient water being given them to prevent actual suffering. Whilst this is being done all the shabby fronds may with advantage be cut off; in fact, when the plants are quite dry at the roots, it will not do them any harm to cut off all the fronds that have been left, although thinning out would be safer where the plants are at all overpotted. These plants, after a few weeks' rest, will again start into good growth and perfect a crop of most useful fronds for the winter season. It will not be advisable to repot any plants from such a stock now, this would rather tend towards a soft growth—in fact, Maiden-hair Ferns are frequently far too much overpotted when this object of a cut supply is the chief and all-important point. When sufficient rest has been allowed them, the plants should be given a fair amount of warmth, but not with too much moisture in the atmosphere. A pit, for instance, from which a crop of Melons has been taken would be a good position; here they would be tolerably near the glass with probably the chance of a slight amount of fire-heat if needed. The all-important matter, however, is to secure a hard growth; this is best done by free exposure to light with a liberal amount of ventilation, and, as before advised, not too much moisture. When the growth becomes free and plentiful, then it must be seen to that they do not suffer at the roots from want of water. In the case of a stock which has not been run upon hard and which has been grown on in the usual way without early starting into growth, the fronds will now be well hardened and in good condition for cutting. These plants will continue to grow for a long time to come, thus forming a good succession of fronds. As in the case of the others, too much shading is a great mistake; this, combined with a moist atmosphere, produces large pinnae, with fronds also that are frequently much too large for use, whilst they never last nearly so long as the smaller ones when cut. Plants grown in this way might, it is true, be considered to be well developed; but this is what is not required from a practical point of view; besides, light-coloured fronds are always the most sought after by

FLORAL DECORATORS as being the most effective. These can only be had when the plants are not grown in too kind a manner. Another point which is by some growers overlooked or not given enough consideration is that of the soil; if too much reliance is placed upon peat, there will always be a tendency towards vigorous growth. On the other hand, by using a light fibrous loam or heavier loam that is corrected by the addition of a little peat, the results will be found far more satisfactory. I have previously alluded to keeping the plants in a fairly light position. This may in some cases (it is so in my own case) be somewhat of a difficulty, particularly where the majority of the houses are specially devoted to fruit culture, the occupants of the roofs thus imparting too much shade. Rather than attempt to grow the plants in such positions, it will be a better plan to keep the stock in cold frames with a light shade upon the glass if much exposed. Frames can usually be spared at this season of the year; in some instances they are not nearly all to be found in actual use about now, the lights often being for the time stacked away upon their sides. Here, then, those who have a good stock of plants may safely place them when so situated as not to be able to give them a fair chance in their houses. If this were done more than it is we should not see so many Maiden-hair Ferns drawing out a miserable existence in places totally unfit for them. As an instance of this, I would only allude to the one fact—viz., that of still continuing to grow the plants in the heat and moisture of a stove-house at all times of the year, frequently overpotted and as much overwatered. Another fine place for securing a good enduring growth is upon shelves, where the plants have always a free circulation of air playing around them. In such positions they will, of course, be found

to dry up quickly, but this should not be any drawback in the least. The basket culture of these Ferns should be more practised where possible. By this mode of culture a good stock of fronds will frequently be in hand when the pot plants have been hard out, simply because the basket plants are not so accessible at the moment. The smaller growing Maiden-hair which assume a rosette tint will be found to be further intensified in colour when grown fairly well exposed to the light and air, although most of these require rather more warmth than the common kind. *A. tinctorum*, *A. rubellum*, and *A. Veltahl* are three of the best of these to supply occasional fronds in a cut state. Where seedlings of any kinds are seen to be springing up they should be well cared for, a young stock of these being always useful to supply the place of the older and somewhat exhausted plants. Wherever it is possible and practicable also, I would advise the extended culture of Maiden-hair Ferns planted out. This may be done upon bare walls hitherto occupied by merely fixing some wirework to the face with a little soil; margins also to stages may be planted with decided advantage. Besides *A. obovatum* for cutting, note should be taken of *A. elegans*, *A. mundulum*, *A. deflexum*, *A. Williamsi*, and *A. Bausei*.

FLOWERS IN SMOKY SUBURBS.

I WAS much interested by an article on this subject in GARDENING of July 1st, page 241, as doubtless were many other of your readers. I cannot, however, help thinking that "C." has mentioned several plants scarcely suitable for small town gardens to the exclusion of others, quite as easily grown and brighter looking, that succeed admirably in smoky districts. For instance, the German Iris requires to be grown in bold masses, whilst the necessary space cannot be given in small gardens. Again, in such places the Sunflower has a very cumbersome appearance; *Michaelmas Daisies*, too, have a very weedy, decayed look about them. My garden, which is situated hardly a mile from Shore-ditch Church, in the smoky district of Dalston, is generally bright from April to November; but this would hardly be the choice of plants were confined to the list in the article referred to. Amongst perennials, which do well with me out-of-doors (I have no greenhouse or glass of any kind), are *Lilies*—*L. candidum* (the old White Lily), some bulbs of which have been in their present positions eight years, and they bloom freely each year; so also do *croceum* (orange), *avartium* (orange-scarlet), *ohalcedonium* (the old sunset Turk's Cap Lily), and *speciosum album* and *rubrum* (a most valuable and hardy kind). *L. auratum*, on the other hand, do not succeed so well, as they fail after the first or second year. Some *Roses* do well—viz., *John Hopper* (a pink cabbage-shaped H.P.) blooms freely, sometimes twice in a season, and lives for years; and the *Bourbon Rose*, *Souvenir de la Malmaison*, a lovely flower, flushed with pink-white, is a splendid plant for a south-west wall, the buds being a very nice shape when just opening, and although it has not perhaps more than five or six blooms at a time, yet the flowers are produced in succession from May till end of September. *Moss Roses* also thrive, but do not bloom as freely as I could wish.

THE BLUE PASSION-FLOWER makes a grand town plant, blooming with the utmost profusion. I have often had from forty to fifty flowers open at once for weeks in succession; unfortunately, however, it sometimes succumbs to severe frost, a five-year-old plant of mine being killed in the long, cold winter of three years ago. *Clematis Jackmani* (the purple-blue variety) always does well on walls or arches. The *Evening Primrose* (*Oenothera morocarpa*), a trailing variety with large sulphur-yellow flowers as big as the top of a breakfast-cup, succeeds well on rockwork; and so also does *Cresping Jenny*, with its hanging shoots smothered with Buttercup-like flowers. *Aemone japonica alba*, *Delphiniums*, and *Carnations*, are all that "O." claims for them as town plants. The *Double White Pink Mrs. Sinkins* is another good thing; the scent is delightful, and although rather a pod-burster, the blooms, which are produced almost without number, make capital button-holes. *Double Pyrethrums*,

too, do very well, especially the white variety, *Mont Blanc*, and the rose-coloured *M. Barral*; these bloom early in May, and if the stems are cut back to about 6 inches after flowering a second crop is often produced in September. The *Double Convolvulus* makes a very good climber; it has fine blooms, something the colour and shape of the old Maiden's Blush *Rose*, and, if anything, is too vigorous, as it spreads like a weed, requiring constant pulling up to keep it in bounds. The name is given in catalogue as *Calystegia pubescens plena*. *Scilla nutans*, *Snowdrops*, and *Grape Hyacinths* do well on a raised bed or rockwork. Amongst annuals there is a large choice. *Phlox Drummondii* is splendid; *Godetias*, *Purple Scabious*, *Zinnias*, *Linum rubrum*, *Coreopsis*, *Corianders*, *Candytuft*, *French Marigolds*, and the climbing and dwarf *Nasturtiums*, are all exceedingly useful. *Virginian Stock* makes a charming spring border, whilst patches of *Shirley Popples* are startling in the brightness and variety of their hue.

Nicotiana affinis (Scented Tobacco) grows everywhere, and is smothered with its lovely star-shaped fragrant blooms of a pure white colour, filling the garden in the evening with their perfume. *Sweet Peas*, too, bloom freely and for a long time if the seed-pods are constantly picked off (this should be done to all plants if continuance of bloom be looked for). *Snappdragons* and *Tufted Pansies* (*Violas*) are first-class subjects for town gardens; the show and fancy *Pansies* also do well if the season be not too dry. *Double Dahlias* and *Ten-week Stocks* are also good. The latter can easily be raised from seed if sown in a shallow box in February, and hung up under a skylight, and are very useful to fill up the borders with colour and fragrance during late summer and autumn. Of course, there are many others that could be named suitable for town gardens, but I think with a list like the foregoing no Londoner need despair of having a gay and fragrant garden. If I have not trespassed too much on the Editor's space I should like to give a list of the plants in bloom in my garden at the end of June—viz., on walls: *Sweet Peas* and *Tropaeolums* of various colours. *Blue Clematis Jackmani* and *Rose Souvenir de Malmaison*. In borders: *John Hopper*, *Madame Gabriel Luizet* and *Maiden's Blush Roses*, *Nicotiana affinis*, *Snappdragons*; *Candidum* (45 blooms open at once), *Croceum*, and *Testaecum Lilies*; *Annual Cornflowers*, *Shirley Poppies*, *Scabiosa caucasica*, *Clove Carnations*, and other varieties; *Sweet Williams*, *Marigold (Meteor)*, *Evening Primrose*, *Mignonette*, *Pencils*, *Delphiniums*, a few *Phlox Drummondii*, and *Virginian Stock* for a border. In centre beds: No. 1, *Calceolarias*, *Oeranium* (*John Gibbens*), *Blue Lobelia*, and *Violas* (pale-cream with a blue porcelain edge). No. 2, *Calceolarias*, *Geraniums* (*Henry Jacoby*), *Blue Lobelia*, and *Silene ruberrima*. No. 3, *Calceolarias*, *Geraniums* (*John Gibbens*), with a border of *Countess of Kintore Violas*.

H. S., Dalston.

BEES.

4268.—*Bee-hives*.—I would thank "S. S. G." if he would kindly advise me under the following circumstances. A friend of mine some years ago bought several hives of Bees on the property he was taking over. One of these was in a wooden hive, built of old soap-boxes and such stuff, and made to no measurement whatever. As the notion struck the former owner, he added to the height of the box, which, by the way, I first built round an old straw sheaf. The Bees have "raided out" all through the box, building combs from the roof and sides, and mixing things up promiscuously. Last summer I attempted to open them up, and, if possible, transfer them into a civilized hive (bar frame). In this I failed (completely), but got some half-hundredweight of honey, with a delightful assortment of dead and dying Bees, though I handled them as gently as possible. They raged furiously for some days after, and stung any and everyone who came into the garden. I have been asked this year to try again, and I was speculating on the propriety of putting a bar-frame hive, with a false bottom and hole in same on top of the hives it stands, and try to induce the Bees to take to the new hive. The Bees are very strong, as they have great room. I don't like to break the whole thing up, as the queen might get lost, and the brood wasted—in fact, my idea is to try and get the Bees to take up their quarters, hatch out all the brood in the old hive, transfer their stock of honey upstairs, and clean the combs out generally, and to do away with an impracticable old hive that nothing can be fitted on. It's a fearful hash, and appalling to look upon. I'm not an expert, but can manage my own Bees, and do not fear a neighbour's at times, but I confess this is a serious business. Can it be accomplished without stinging too many Bees?—T. H. B.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed before the query replied to, and our readers will greatly oblige us by adhering, as far as their knowledge and observations permit, to the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4250.—*Roses in borders*.—What *Rose* continues in flower in out-of-door borders the longest?—A. E., SUDBURY.

4251.—*Fancy Pansies*.—I should be glad of some information on the cultivation of fancy *Pansies*?—BURTON-ON-TRENT.

4252.—*Manure for Roses*.—Is Rape-dust or bone-dust too strong a manure for *Roses* in out-door borders?—A. B., SHEFFIELD.

4253.—*Rhododendrons in a clayey loam*.—Can I grow with any chance of success *Rhododendrons* in a good light clayey loam?—SCROGIA.

4254.—*Best Gooseberries*.—Would someone kindly give me the names of eighteen to twenty-four best *Gooseberries* for dessert and cooking purposes?—BIRMINGHAM.

4255.—*Double Pyrethrums*.—As I am about to grow double *Pyrethrums*, I should be glad of any information respecting them as to cultivation, best time for planting, &c.?—BURTON-ON-TRENT.

4256.—*Colours flowering*.—Will anyone kindly inform me how I can grow these plants so as to prevent them flowering, and the proper size of pots to grow specimen plants in, and soil?—CONSTANT READER.

4257.—*Plants in a bedroom*.—I have a room facing due west, and shall be much obliged if someone will kindly tell me what plants are likely to flourish and flower well in it, and also how I should treat them?—M. B. C.

4258.—*Lilies after flowering*.—Will someone please inform me what to do with *Lilium auratum* and *Lilium Harriet* after flowering in order for them to bloom well next year? What is the reason?—B. ROBERTS.

4259.—*Flowers in a garden*.—I should be greatly obliged if someone would tell me how I secure flowers in my garden the greater part of the year? What should be planted or sown for spring blooming, and when?—DEVON.

4260.—*Borax and plants*.—Would someone kindly tell me if powdered borax is injurious to plant life? Both it and alum banish blackbeetles, and I should like to try it for slugs, &c., if it would not injure the plants?—A. E. DALZIELL.

4261.—*Winter flowers*.—What will be the best plants to have in hand now to furnish a continuous supply of flowers for out-of-door through the winter months in an ordinary greenhouse kept at a temperature of about 40 degs. F.—SCROGIA.

4262.—*Seeds of "Geranium" and "Fuchsias"*.—Will someone kindly inform me when is the right time to plant the seeds of "Geranium" and "Fuchsias," and when to put them into pots, and should they be placed into a greenhouse or not?—O. CLARK.

4263.—*Weeds on a lawn*.—During the late dry season the weeds on my lawn have got ahead, particularly a yellow Hawkweed, which increases rapidly. Will someone kindly tell me the best way to prevent it from spreading and to eradicate it?—C. H. F. C.

4264.—*Plants for a south-east conservatory*.—Will someone kindly tell me the best plants for a conservatory with a south-east aspect at Beckenham? I have hitherto failed to grow anything in it to my satisfaction, and I do not want to devote much time to it.—J.

4265.—*Carnations and Pinks for the open air*.—Will someone kindly give me the names of the best dozen *Carnations* for the open air (*Gloosetair*), all *lily* loam? Also the best half-dozen *Pinks*? I want them to be as distinct in colour as possible.—C. W. W.

4266.—*Mountain Cudweed on a lawn*.—I have an old lawn now being overgrown with *Cudweed* which I have tried to pull up, but the roots run along for some distance, and then break off. Will someone oblige me by saying if it is possible to extirpate them?—W. B., Edgbaston.

4267.—*Rose "La France"*.—What situation is best for *Rose La France* (dwarf)? I have one in a south aspect, and each year it gets so thoroughly blighted with caterpillars that the blooms seem withered as they form. Should it be moved, and, if so, when and where?—E. ROBERTS.

4268.—*Rose not thriving*.—I should be much obliged if "J. C. C." or "B. O. R." would tell me the reason why my *Rose*—Mrs W. A. Richardson does not grow well? I planted it in a border against the house wall last October in a bed facing south, with good rotted soil and manure.—BIRMINGHAM.

4269.—*Treatment of a Hydrangea*.—I should like to know what to do with a *Hydrangea* I bought in October last? It had been cut down to within about 3 inches of the soil, since I purchased it, it has thrown three or four shoots about 1 1/2 feet high, but has never bloomed.—BIRMINGHAM.

4210.—Planting Christmas Roses.—I want to make a small plantation of Christmas Roses. As I'm moved to my present abode a month ago I could not do it early in the year. When would be best time to effect my purpose? The plants I must buy. Should I do it now or wait till October?—BIRKENHEAD.

4211.—Strawberry growing for market.—Will this year in Somersetshire? Of course, the fruit would have to be sent into large towns and disposed of; but it is good warm land. What sort would be best to grow for market or general culture, and what would be the usual average weight of produce per acre in good seasons?—G. D.

4212.—Peaches in pots.—I should be glad to know if Peaches can be successfully grown in pots in a cool greenhouse facing south? If so, which are the best sorts, what time of year should they be started, and what is the proper treatment as regards pruning, soil, &c.? Are they difficult to manage, and do they require much attention?—MURK.

4213.—Potato Onions, &c.—Would someone kindly give me the correct botanical name for the "Earth or Potato" (Gaulth) I mean the kind of which you plant the "and" many other bulbaceous attached to it. Also, what is the right time to plant or sow it? Any information as to prevent cropping of a vegetable garden would be greatly obliged.—DEVON.

4214.—Fowls in a field.—I have a small field of 2 acres or 3 acres, sowed like all others, have a very small crop of hay this year, but now it is growing again. Two or three persons whose gardens run on to the said field have let their fowls into it, although asked not to do so. What can I do with them, as they scratch and pick all the best of the new Grass and spoil the growth?—G. CLARK.

4215.—Arum Lilies for Christmas and Easter.—I want my Arum Lilies to flower at Christmas; what treatment must they have? After blossoming they have been placed in open ground for 2 months and have died back, where they are now sending up young leaves. My greenhouse is only kept up to 43 degrees of heat in winter. I also require some at Easter. What treatment is needed?—A. BOSTONIAN.

4216.—Pruning hedges, &c.—Will someone please to say when should privet hedges be pruned, also quick hedges? My gardener has not done them yet and says it is too soon for "would have to cut them twice." Also kindly say if Roses were properly cut in last season should there be now a quantity of old wood on Fisher Holmes, Boule de Neige, Captain Christy, &c.? He says the best heat has done this. Advice acceptable.—X. Y. Z.

4217.—Carrots failing.—I have a bed of Carrots, which up to a week ago appeared to be flourishing; but a space about a yard square suddenly withered, and on examining them I find they are attacked with what looks like a small white centipede. The ground has been well worked and manured. I notice other plants on the same bed here and there drooping from the same cause. The carrots about 3 inches or 4 inches long. I should be glad to know what should be done to the land when the crop is off to kill the centipede?—H. SANDYBAY CLARK.

4218.—Fruit-trees for garden walls.—In the autumn I am going to plant fruit-trees by my garden walls, the most common being Pines and Apples. Would someone kindly advise me whether I should do best with pyramids or those to train to the wall, and what sorts are considered most suitable and profitable? I prefer trees producing well and of the kitchen varieties. Of course, I might vary and try a dessert kind or two if there would be no difficulty as to a crop. My garden is suburban, entirely removed from manufactories, and very open. The soil is a good turfy loam, fairly deep on gravel beds, water being found at a depth of 5 feet.—W. PRINCE.

4219.—Treatment of pot-Roses.—I shall be pleased if anyone will inform me what will be best to do with pot-Roses that have grown leggy and are without much foliage? I have several good plants, but that is their fault. They are now out of flower, and have been cut down to the ground, but only from the top. I do not care for any more flowers this year. I only want them to be in bloom in a cold-house, say the middle of next June. Should I cut them hard back now or let them grow on till next spring? Any information with respect to the above will oblige? Some of the varieties are named Captain Christy, Merville de Lyon, La France, Ulrich Brunner, Etienne Levot, Marie Beaumann.—YORKSHIRE.

4220.—Erigeron aurantiacus, &c.—Will some expert give a hint for growing Erigeron aurantiacus? I have failed utterly. The plants do not die, but gradually withdraw into Mother Earth. Rich soil, poor soil, east, west, and south aspects, all have been tried. But I have many other plants that grow like weeds. Shorter grass-cultures in shade, post seed grit (on a loam foundation), and shelter. In the same bed Epigea repens is growing gloriously. It will be covered up with a thick blanket rubbed with vaseline, from December to March, as I consider it worth any pains bestowed. One spray dipped with blossoms will last a week and fill the room with the perfect fragrance. Also, should they be watered, half rose.—MRS. SANDYBAY CLARK.

4221.—Gathering and storing Peas &c.—I should feel obliged for information on above, as after all the cultivation of fruit-trees is for the enjoyment of their produce, and to gather the most or the best crops away the trouble and labour in bringing trees to perfection. I have the following with slices when fit for use by catalogue: garden in Isle of Wight, so perhaps earlier: Louise Bonne of Jersey, October; Duchesse Angoulême, October, November; Plumetion Duchesse, October, November; Williams' Bon Chrétien, August, September; Jargonelle, August; Centre Clairgeau, November. Some, I believe, should be eaten from the tree, and others be gathered a long time before maturity. Also, should they be watered by belches, and which kinds should be kept in the dark or in the light; if in the latter, how long before required for use? The best means of protecting pyramids and standards to prevent birds eating the stem portion of fruit, by which many crops are completely destroyed in my garden?—J. COL. D. L. BRANT.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4222.—Oatlaya Rex (R. C. F.).—I will have something to say about this flower next week.—M. B.

4223.—Epidendrum species.—Learner sends me the bulb of an Orchid requiring its name, and I think it is an Epidendrum, but as there are between three and four hundred plants known by that name, I cannot tell him which one it is. I must decline to answer, therefore, until it flowers.—M. B.

4224.—Tuharous Begonias (David Griffiths).—You should give these a little Gray's fertilizer, about a spoonful once a fortnight to start, and you would find them gather a great deal of strength, the plants like this I have just given mine their accustomed dose, and these are now flowering very freely.—J. J.

4225.—Oryctolium maculatum (Learner).—I think this is the plant of which you send me a spike of bloom. It was introduced about fifty-five years ago when this genus was commonly used for it, and the plant was well known in my earlier days by this name, but I think Lindley had long before included it in the genus Oncidium, but you may call it whatever you like best.—M. B.

4226.—Oatlaya otrina, which has done flowering (R. C. F.). The plant will now be forming new growth, and it requires to be hung up in the Cattleya-house in that portion devoted to the Lælia excepta. The plants should be placed in a nice sunny position, and they may be syringed every morning and evening. They will not get too much water during the time they are growing.—M. B.

4227.—Dendrobium formosum (H. B. Evans).—This in the name of the flower you send. It certainly is not D. burmannense. It would appear to be a low country plant, and it requires to be kept in good heat and moist for the greater part of the year. You say you have it flowering freely, in which state it is very beautiful. The flowers are of a more convenient size for a lady to wear than D. formosum giganteum.—M. B.

4228.—Ferns for exhibition.—J. Coleman asks me to name a dozen of the best kinds for show purposes; but he does not say what he wants, British and hardy kinds or exotics, and if the latter such reporters as say of these that Mr. So-and-so exhibited a "group of six large Ferns of the common exotic species," is misleading. Evidently the common exotic species is at a discount. Will someone tell me what that is?—J. J.

4229.—Oncidium macranthum (H. M. Turner).—Well, it is late for your plant to only now to be coming into flower; but I hope it will come, and that it will prove to be a very good form. You say you purchased it of Mr. Oppner, of Cheltenham, and that is a good firm, and if he had flowered it previously he could have told you before to take his place; if he sold it as an exalted plant, you must flower if to know it is a good variety or not.—M. B.

4230.—Oncidium labelliferum (H. B. Evans).—I have no doubt but the spray sent, and which you say was produced from a plant bought under this name is incorrect. It is nearly allied to O. curium, G. Gardneri, and G. pratense, and, indeed, some make it to be synonymous with Gardneri, from which, however, it appears to me to be quite distinct. I should certainly retain the name, and maintain its distinctness, and I could see by comparison reason for changing it.—M. B.

4231.—Cypripedium longifolium (T. Atkins).—This is the name of the flower you send, and not O. Spicatum. I do not know two plants that are more different and distinct. The first belongs to the Sciadopodium, and the last to the true Cypripedium. The first is found in the mountains about Cherqui in South America. Stones are found in Borneo, on the limestone hills about Sarawak. It is very wrong for anyone to so mislead persons in the naming of their plants.—M. B.

4232.—Oncidium species.—F. J. Hamilton sends me a spray of what appears to be a kind of Oncidium; but as the flowers are not such as I have seen in cotton-wool, which is the worst material possible to use for this purpose, it was no wonder that they were shrivelled beyond recognition. You have waited a long time (ten years) for the flower. However, you have gained your point at last, and I should like to help you to name. Can you not make a drawing of it and send?—M. B.

4233.—Epidendrum vittatum majus (H. M. Turner).—The flowers you send appear to have been attacked by thrips, although there were none visible on the flowers; but I advise you to take care the houses are cleaned of these pests. I have observed that thrips abound this season in and about the border flowers, and your houses are doubtless contiguous to these, and they have migrated from one to the other. See that these insects do not gain a footing, or you will simply lose the beauty of the flowers for the present season.—M. B.

4234.—Odontoglossum hastilabium.—Thos. Cooke says how is this? His plant showed two spikes of bloom at the beginning of June. They grew to within 1 foot and 3 feet in length, and when he expected to see the blossoms he had to give up, as the spikes were so small, with a quantity of black specks upon it. Well, now, I should imagine "T. C." has kept the atmosphere too hot and too dry, and that the thrips which are so prevalent on the outside flowers have got to the inside plants, and have marked the spikes of his Odontoglossum for their prey. Well, he must get rid of them, and see that the pest are killed, and that the atmosphere is kept in a moist and cool condition. Thrips cannot stand a moist condition of the atmosphere.—M. B.

4235.—Odontoglossum cirrhosum (J. Dunford).—This is the name of the specimen you send and not O. nevium, which, however, is not so rare as it was before Mr. Sander introduced the last named beautiful plant, which no one had found in the last decade or two, since it was originally introduced by M. Linden of Brussels. The present species although beautiful cannot compare for elegance with O. nevium. The sepals and petals have thin seed lengthened out into long tails. These are creamy-white, bisected at the tip, and are of the same colour with some yellow. It thrives along with the same species in the coolest house. I think it is to Mr. G. Bull, of Chelsea, to whom we are indebted for the instance for this plant in a cultivated state.—M. B.

4236.—Odontoglossum Pascoarei.—I have received this plant in three forms from two readers. One of them says he has these two forms from some imported plants. The one marked 1 is a very large flower, but it is more stately than the specimen generally. I should advise the sender, "T. M.," to grow this on for a time, when, perhaps, the flower will improve in shape, and if it does it will be a grand one. The flower marked 2 is a variety having the back of the sepal and petals streaked with rose colour. The flowers, "H. B. Evans" sends are not large, but they are beautifully spotted and blotched and spotted on the lip with magenta-purple. I advise both my friends to continue to grow them on, then the flowers I expect will very greatly improve. You should remember the finest variety of Pascoarei that we have, called Veitchianum, developed its fine colours after being seen in bloom with a very little colour. Watch and wait.—M. B.

4237.—Treatment of Dendrobium.—G. F. W. appears to be in trouble about a plant of this genus, and he asks should D. nobilis be quite dried off in August? No, I think not. It would scarcely have finished up its growth by that time. Watch when the bulbs are about ripened up, when you should begin to withhold water until none is given, then remove the plant into a cool-house, keeping it quite dry. The plant should not be removed into the warm-house before the buds begin to show. D. speciosum should certainly not be dried off then, its growth not being finished, but when this is made up it may be kept quite dry. D. Devonianum when finished up should be hung in a sunny position in the greenhouse and be kept dry until the bulbs are quite ripened, when it may be taken into the growing-house again; but, of course, this will be much cooler than it was, and give just enough moisture to keep the bulbs from shrivelling. D. soaratum, being a stout bulbous kind, may be kept quite dry, saving just enough moisture to keep the leaves from becoming yellow. D. Jamesoni I never heard of, so I cannot advise upon this one.—M. B.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to the Editor should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—F. Z.—Arilla labellata.—D. L. H.—Ceanothus aureus.—Chafedell.—Thorn Apple (Datura Stramonium).—Kilridge.—Diplazone (Mitsunaka glutinosa).—Sedum Ewersi.—Noria.—Bygonia Drezoi.—James Church.—Oxyphthalma paniculata.—South Staffordshire.—1, Begonia metallica; 2, Eranthis species; 3, Cereus speciosissimus.—J. Robertson Gray.—Yes, Labrador Teapack.—J. Cooke.—Specimens all rotten through being in damp glass. The best book you can get will be "Dictionary of Gardening," W. Nicholson, published by L. Upcott Gill, and Co., 170 Strand London, W. C.—L. P. S.—You really must send fresher specimens, and do not pack them in damp Ephemera. They are quite unrecognisable. In the inside.—1, Sedum kamisobadum; 2, Sedum kamisobadum var. 3, Not recognised; specimen too much dried.—William Storer.—Lilium chalcidicum.—F. Polegate.—4, Berberis Darwini; 5, Lycopodium formosum; 6, Pyrus Aria.—Hudson.—Clematis lanuginosa var.—F. E. Richmond.—Stachys lanata.—F. Forell.—A St. John's Wort (Hypericum) species.—M. Cade.—Impossible to name from such bad specimens.—Lyndon House.—Flower, Justicia carnea. Other specimens send in bloom.

Names of vegetables.—W. P.—We cannot undertake to name garden varieties of Peas.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

J. M.—Apply to Mr. T. Smith, Daley Hill Nursery, Nawry, Ireland.—O. P.—Send address.—S. C. O.—The plants are affected with the grub of the Marguerite Daylily. Pinch the leaves and do not destroy the grubs. Some of the worst leaves should be picked off and burnt. The matter has been treated of in GARDENING very many times lately.—A. Agrimur Chancellor.—We regret that we have not been able to make use of the negatives sent.—V. M. C.—We know of no book which contains anything like so much information on the subject as a volume of GARDENING. Any questions sent will be replied to.—John Williams.—The warps on the Vine-leaves are caused generally by too high and moist an atmosphere. Give freer ventilation, and no doubt the mischief will sensibly abate.—F. L.—The netting can be procured through almost any good seedman.—Ada.—Ripen the Peas and keep moist at the roots, and well expose the leaves to free them from dust.—Charles Davies.—The letter was received, and, we believe, answered. If not, please repeat query.—Amateur.—"Dictionary of Gardening," by W. Nicholson, published by L. Upcott Gill, 170, Strand, London, W. C.—M. M.—We have now only very early flowering Chrysanthemums. The mischief to the Lettuce seems to have been caused by the drought in the early summer.—G. P. Pittner.—Apply to the Garden Superintendent, Hattersea-park, London, S. W.—John Griffiths.—Takin and read GARDENING regularly, and send in any queries you like. You will get more information than from any book.—Creddon.—No doubt the judges were quite right in disqualifying you, as you showed two kinds of Tomatoes, and so had three sorts of vegetables.—An Amateur.—The Passion-flower pod seed is the fruit, and when ripe should contain seed.—J. Boulter.—The plants are affected with the Oudemans disease, for which there is no remedy; but clearing all our soil and all, and having a fresh start; half measure are no good.—Harry Brownrigg.—Please repeat your queries in a clear form as to plants you wish to know about, and give your name and address, please.—South Staffordshire.—The lettuce are no doubt wire-worms. Treat them with slices of Carrot as has often been described in GARDENING.

Drawings for "Gardening."—Readers will be glad to know that we have had several specimens of beautiful rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in our next number, and will appear in due course in GARDENING ILLUSTRATED.

CHRYSANTHEMUMS.

SELECTING THE BUDS.

SELECTING the buds is perhaps the most important point of all the details connected with Chrysanthemum culture, because if the right bud is not chosen it is impossible to obtain a perfect bloom. Instances of this occur frequently. Many complaints during November reach me of flowers which have hard green centres, do not develop, and throw out their petals in an irregular manner. In the case of the Queen family the petals are reflexed instead of incurved. Amongst growers there is a common term employed of "taking the buds." When a bud is forming at the point of the shoot, growth will cease for a day or so and again push into activity by the production of numerous growths on the same shoot. As a rule, shoots will spring first from the nodes below the flower-bud; in some instances as many as ten growths will push. In all cases the three top shoots grow much the faster, owing to their extra strength being at the apex of the plant. When these shoots are a couple of inches long, the flower-bud will then be sufficiently formed to admit of the cultivator being able to judge of its perfect form or otherwise. Sometimes, owing to a bruise or an attack from some insect pest, the bud does not present a perfect shape—round and clean. If this is so, it is useless to allow it to remain and expect a perfect bloom. Preparing, then, that the bud is all right, the side growths named should be removed to concentrate the whole energy of the plant into the bud selected. If the shoots are allowed to grow, say, 4 inches or 6 inches long, they are all the time robbing the bud of its store of nutriment. The

BEST TIME for taking the buds or removing the shoots is early in the morning, or in the evening when the dew is upon the plants; the shoots at that time are quite brittle. If the stem is held secure in the left hand and the young growths which are intended for removal be bent suddenly down one at a time, they snap off. After a little practice this method of taking off superfluous shoots is more expeditious than cutting them off with a knife, but if the operation is effected during the middle of the day when hot and dry, the shoots are quite tough, and the risk of damaging the flower-bud is much increased. As a safeguard against accident in the manipulation of the buds and shoots, some growers retain one shoot at the point for a time until it is seen that the bud is safely swelling to a good size, but this, I think, is wrong, as the growth is divided between the bud and the shoot retained, and the latter must to some extent rob the flower-bud of its due amount of sap. If any doubt exists that the bud has been injured, the retention of a growth shoot near a bud is advisable, as this will in due time produce another bud. I have explained at some length the method adopted to "take" the buds. Readers will be anxious now to know when this all-important point is to be carried out. Much depends upon a variety of

circumstances. For instance, one variety will need to set its flower-buds fully a month earlier than another; still both will be in flower at the same time. This is one of the details which experience of each variety alone can teach. Then, again, there is the difference in various localities. Take, again, the vast difference there must be between, say, the counties of Durham and Devonshire, for instance. Growers in the latter county have much more difficulty in obtaining perfect blooms than those residing in the North, or, say, the Midlands. This latter district is the most favourably situated of any in England, because there, what are known as crown-buds can be depended upon to give the best blooms.

CROWN-BUDS are those which result from the second natural break. Where crown-buds can be depended upon in the case of some incurved varieties to give the finest blooms, say, North of London, flowers produced from the same class of bud in the South would be quite useless. I mention this to show that no hard and fast rule can be laid down that will suit all parts alike. Japanese varieties need earlier bud selection than the incurved section, for the reason that size is of more importance in the former than in the latter, and in the Japanese blooms there is none of that evenness of petals to consider. E.

THE TUBEROUS BEGONIA.

THIS year the Tuberos Begonia is not satisfactory—at least, not so bright in the garden as in cooler seasons. The reason is that the plant dislikes hot sun, which scorches the leaves and of course stops short the gay display that it is capable of making under more favourable conditions. But with cooler weather this fine bedder will "pick up," and create a wealth of colour later, when one may reasonably expect not another hot sun. Few things have undergone greater improvement, both in habit and blossom. Hybridists have raised up a class characterized by dense growth, compact, and neat, the flowers broad, robust, and displaying a great variety of colours from orange to vivid scarlet, ranging through a delightful series of refined shades, white, touched with salmon or peach. The simplest way to get a stock is to raise seedlings, and so great is the advance in all that concerns the Begonia that if the seed is purchased in selected colours, the plants may be depended upon to come true to those colours. Sow the seed early in the year in shallow pans or pots filled with very light soil, and the seed is so fine that it will not be necessary to cover it with soil, but merely sprinkle a little fine silver sand over it. Place on a gentle hot-bed or in a warm house, and when the seedlings are large enough to handle, pinch them off into other pans, from which they may be transferred singly into small pots. If the seed is sown in January the plants will be of sufficient size to bed out late in May, an excellent display of flowers rewarding the ardent amateur through the summer and autumn months. The corms may be taken up when frost has played its pranks, and stored away in a warm place until the spring. Then pot them, starting slowly into growth in November

pit, and syringing once or twice every day, but always harden the plants off well before bedding out. A rich, fairly light soil is essential, and if a little peat is incorporated into the bed much good will result, as Tuberos Begonias grow well in peat. Shelter is necessary from cold, cutting winds, but moderate sunshine they enjoy. The method adopted in planting is a question of individual taste. Contrast the colours harmoniously and beds of one colour are charming, or say white, with an edging of the variegated Dactylis. The white-flowered varieties are exceptionally beautiful. V. C.

New Carnations.—Several new Carnations of great merit have been shown this year, and readers of GARDENING may care to know their names. I see that a strong reaction is taking place in regard to the selfs which a few years ago were placed quite in the background. A good addition is a variety named Jim Smyth, unfortunately not a pretty name. It is curious that although there is no want of pretty and appropriate names for flowers, little regard is paid to the important point of nomenclature. This kind is a good self, rich scarlet, a full, handsome flower, which does not split the calyx in the least. Such kinds are much wanted, but it is satisfactory to find that if a Carnation produces flowers with a split calyx it is considered practically worthless. This was not the case a few years ago. I recently made note also of a few other good selfs. Bendigo is deep purple, and a full, striking flower, useful for its somewhat uncommon shade of colour. A charming shade is that of Water Witch, a delicate blush, and both Ellen Terry (white) and Heyes' Scarlet, which has flowers of a bright shade, are of note. It is worthy of remark that the Yellow Carnations are improving greatly. The colour is very charming but unfortunately the plants are very poor in growth. They make few shoots, and these usually have a weak, sickly look, which quite destroys their beauty. However, we seem to be getting a race of Yellow Carnations of really strong growth, such as A. Campbell and Duke of Orleans, both very fine varieties as regards the colour of the flowers and also in growth. When the plants are really vigorous and free, a group of this coloured Carnation is pleasing.—C. T.

Lilium auratum.—No wonder that this gorgeous Lily still remains so popular, and that such a large quantity of bulbs are annually imported from its native habitat in Japan. If the bulbs are potted up in good turfy loam during the winter and covered with Cocoa-nut-fibre in a cool house, they will start vigorously into growth in spring, and if kept cool and near the glass, they will produce splendid heads of bloom in July, and they make a fine display in the conservatory just at a time when flowering plants are limited in variety. The perfume is too powerful for room decoration unless there is ample ventilation, but in the conservatory or greenhouse they are quite at home; after the blooms fade, set the pots out-of-doors and gradually reduce the supply of water, until the leaves die, when the pots should be laid on their sides and the bulbs re-dried.—J. G. H.

GARDEN WORK.

Conservatory.

Where winter flowers are important attention must be given now to Zonal Pelargoniums which are coming on in a sunny spot, with their buds all picked off as they appear. Do not give large ebullitions. If the pots are not well filled with roots the plants will not get the growth sufficiently matured to flower well, and I may say, without a warm, light house to winter them in, their blooming will not give satisfaction. One of the most useful winter-flowering plants is the old Ivy-leaved Pelargonium, Mme. Crousse; the flowers are semi-double, and are produced very freely. The best place for them is a book shelf or a lean-to house. Plants of several years' growth, the shoots trained down the roof, will produce a good supply of blossoms for outting in winter in a genial temperature. These plants may be carried on year after year, being pruned back, say, in June, and the young shoots which break away trained over. They may be grown in large pots when the plants get old, or boxes will do, though for winter blooming I think I prefer pots—10 inch pots will be large enough to hold plants that will cover a roof 6 feet down. These Ivy-leaved Geraniums will cover larger space planted out against the wall, but the growth is not so short jointed, and does not flower so freely as when grown in pots of moderate size, in proportion to the age and size of the plants. If any hard-wooded plants require potting see to it at once, and get the plants well established before the short days come. Already the days are visibly shortening, and the maturing process of all plants intended for winter blooming is now going on. Winter-blooming Heaths must now be fully exposed, and not standing in a crowd. The same remark applies to the berry-bearing Solanums. Young plants of Bouvardias should go into 5-inch pots, and be brought on quickly to a good size. I do not favour the planting out system for these plants, as there is a difficulty in getting the plants established again after lifting. Azaleas in rather small pots in a pot-bound condition may have weak liquid-manure; clear soft-water will do. Lose oil time over to orderleg in the bulbs for potting. Freesias and Roman Hyacinths should be got to at once, the latter being plunged overhead in Cocoa-fibre. Hyacinthus scandens, five or seven bulbs in a 5-inch or 7-inch pot, come in useful for mixing with Ferns or other plants in the autumn. Till the end of the autumn season still outside, and which are kept back for later blooming, should be neatly staked and be kept in a sheltered place, and must be taken outside before the blooms expand. The conservatory will not require so much shade now the weather has changed, ferrets, if any are present, must be kept down by speaking or syringing with an insecticide. Sow Mignonette in 5-inch pots, and thin out the plants soon last month.

Stove.

One of the matters to be kept in mind now is the ripening of the growth, especially of winter-flowering subjects, hence shade should only be used when the plants would be distressed without it. A little more ventilation may also be given. Sudden changes are not desirable at any time. The good cultivator will so arrange matters that a little change necessitated by the changing seasons will merge into each other almost imperceptibly. Many of the stove-plants have been moved to other quarters to ripen. Winter-flowering Orchids, for instance, are in the vinery, where the dry, yet genial warmth will fill up and mature the pseudo-bulbs, and insure good orrleed blossoms when their season comes round. Gardelias are in a cooler house getting the wood formed, but I dare not move them to the vinery, for I am afraid with all our care there is a suspicion of mealy-bug. What a dreadful pest this is among stove-plants! Fir-tree-oll is, perhaps, as good as anything, and better than most things for its destruction. Eucharis lilies will bear cooling down now to have more heat later on to produce flowers for winter. It will soon be necessary to commence fires regularly again. Hitherto we have only used artificial heat on cold nights and wet days, and when the pipes have been warm at ten o'clock at night the fire has allowed to go out. In the face of a strike among the coal miners this is not a time to use fuel extravagantly.

Ferns under Glass.

There are, or should be, in good condition. Some of the variegated Pterises are very effective among the green-leaved Ferns. Pteris argyrea, P. Mayi, and P. cretica albo-lineata are all very easy to cultivate. The different forms of Nephrolepis may be increased now by division. There are beautiful for basket-work. N. devilloides furnum being especially serviceable to a basket. Ferns are frequently grown under the shade of other plants, but if the shade is very dense the fronds are not of much use for cutting. I am growing Ferns now under Cucumbers, and on the whole they do fairly well, and as by this time the Cucumbers will be removed, and their house given up to the Ferns, the latter will have time to harden a bit before the season when much cut Fern is required for bouquet-making, and other decorative work in here. The Lygodium, or climbing Fern, are graceful and pretty, and may be used for trailing over the handles of ornamental baskets, or to hang down round the edges of outflower stands. They are easily grown, and may be rapidly propagated by division.

Mushroom growing

will chiefly be carried on now in the open air. The beds usually do well in a cool, shady spot. Wooden shakers are useful for plucking over the beds to throw off heavy rains. Mushroom beds are best exposed to rain, and for this season a water-proof cover is very desirable. A genial shower will not damage the prospects of the Mushroom-bed, but if it comes heavy it will be an arduous the covering of litter, and a wet covering on a Mushroom-bed sometimes entices the spaw to work on the bed, and the bed is thus weakened in its productivity. Of course, Mushroom beds in bearing must have sufficient water. Liquid-manure, in which a little salt—say a table-spoonful in a three-galloon can—has been dissolved will benefit and

stimulate the spaw. Get the Mushroom-house thoroughly cleared out; neglect of this very often leads to the presence of woodlice and other treacherous insects. It will soon be time to look up materials for making up beds for the house for autumn and winter. It is not likely the sun will be so hot again this season as it has been. Other beds may also be made up outside if there are the means of sheltering them.

Window Gardening.

Those who have Myrtles and other plants they may wish to propagate may put in outtings now. Four-inch pots are the best, and about five outtings can be placed round the sides of each pot. Put 2 inches of broken crocks or charcoal in the border, then a little Moss, and fill in with sifted soil of a light, sandy description pressed down firmly. Put a layer of sand on the top, make a mark with the bell-glass, and outside the mark dibble the outtings.

Outdoor Garden.

Those who grow hardy plants from seeds will probably, if the seeds have been shaded and watered during the dry weather, have a lot of pricking off to do now. Well-flowers, Pansies, Canterbury Bells, Carnations, Pinks, &c., must be singled out if they are to get strong. There is yet time to sow Pansies, Actinorhizums, Hollyhocks, Iceland Poppies, and many other things to biennial and perennial may be sown with the certainty now that rain enough has fallen to soak the ground that the seeds will grow. Hardy Annuals, suitable for early blooming, may be sown now. Gather seeds of anything good to either annuals or perennials. A good strain of Canterbury Bells, Sweet Williams, and Sweet Peas are worth looking after. Good seeds of the White Everlasting Pea, if isolated, will come fairly true, and this is very desirable to have a quantity for cutting and to make a sowing over so arch or against a wall, or up the stem of a Labourer, say other small trees, or the stems of Intermittent Stock, the white variety, are the best varieties. These may, if preferred, be sown in boxes, though they will do very well to the open ground. The best plants should be potted up meantime, and be wintered in a cold frame. They may either be potted out in the spring or shifted into larger pots to bloom in the greenhouse. When well done they are always attractive, and are among the sweetest things for cutting in spring. Roses may still be budded—so far, I expect a good deal of budding remains to be done yet for the present year. It is best to avoid the drought. Carnations also may still be layered. The earlier this work is done the better. Outtings of the flower-stems of Hollyhocks will root now in a frame or under a hand-light in seedy soil. Cut the side shoots into single joints with half an inch of stem above the bud, and about 1 1/2 inches below. Press them into the bed and water to settle.

Fruit Garden.

Fruit thinning the heavy crops of Apples and Pears. Apples will be large enough for use, and the Pears will do for stewing. Dessert Pears are very useful for this purpose. Finish the summer pruning. It is best to make the surplus wood on the trees longer. There may possibly be a little lateral growth till the autumn damp; but what of that? It will do for less harm than leaving all the summer growth to shade the fruit and drive the roots down into the subsoil for moisture. Moreover, when the trees are left unpruned till late in the season all the extraneous wood drawn away from the back buds can their main branches, when they are to form, be a source of winter young trees which are making too much wood should be noted to be lifted, and the roots brought near the surface just as the leaves are on the point of falling. It is a great help to fertility to lift young trees when about three or four years planted. Keep down lateral growth on late Vines. They should be gone over and the young shoots rubbed out once a week. Late Grapes will ripen earlier this year. Evre Gros Colman, which has had on fire since the beginning of June, and colouring. The borders inside must not be allowed to get dry. A mulch of loam litter on the inside border will be an advantage. It will keep down the damp when the Grapes are ripe, and prevent dust arising. The ventilation must be as perfect as possible, and be worked in sympathy with the outside temperature. It may be necessary to cover the ventilators with scrim to keep out wasps, and bottles of beer and sugar should be hung up inside the house to attract flies, &c.

Vegetable Garden.

Things are moving on rapidly since the change in the weather with more rain set in, and the time to make provision for winter vegetables. It is a deficiency of Winter Greens has not been got in, but about it in rural earnestness. It is full late for Brussels Sprouts, as they ought to have been out at least a month ago; but Sutton's Tom Thumb Savoy, Chou de Burghley, Hearting Kale, and Rosette Coleworts will all come in useful—perhaps more useful than Broccoli, which have of late years been so uncertain. Other winter crops to which attention should now be given are, Broccoli, Turnip, and other Greens, Green and Batavia Endives, and Obevil Radishes and Mustard and Cress can be sown according to demand still in shady positions, the soil to be kept moist. Celery may be blanched by tying paper round the plants to exclude the light. Celery blanched in this way looks cleaner and better, and there is no doubt that for exhibition this is the best way to blanch it; but for home use I like blanching with soil or something which excludes the air, more especially the paper does, and, of course, for winter use the danger of injury from frost has to be considered. Paper is not a sufficient protection. For late use strong plants of Red Celery may still be potted, giving a preference to those plants which have been raised outside altogether. Plant in very shallow trenches, or all together on the surface. The plants will not reach a full size, but they will come very useful in the kitchen. If very early Tomatoes are required early spring it will soon be time to start the plants either from seeds or cuttings. The plants now fruiting, planted in light houses, will carry on as till Christmas. E. Hoar.

Work in the Town Garden.

Plants will soon be in all their glory, and very beautiful in ways where in even fairly good cultivation. The plants of the few flowers that are over seen to the

Since the rain came the plants have grown amazingly fast, and what they chiefly need now is to be securely staked and tied as they grow, removing any weak and superfluous growths, and to wage constant war against sawflies, which are unusually common this season. When the flowers are grown for show it is usual to protect them from heavy rain by means of metal caps or inverted flower-pots fixed immediately over them; but for ordinary garden decoration, cutting, &c., nothing of the kind is necessary. Much the best traps for earwigs are small pots, half full of dry hay or Moss, inverted on the top of the stakes, the contents being turned out and destroyed every morning. This, with a few lengths of hollow reed or the like placed among the leaves will soon lessen their numbers. The Herbaceous Phloxes, again, are wonderfully showy and altogether delightful plants, particularly charming when seen in large masses of well-blended colours. They do not thrive to any extent in very shady gardens, but in herbaceous districts, or where there is a fair share of light and fresh air, they grow well and flower profusely, while their culture is of the simplest. Those who desire to have fine masses of the hardy Chrysanthemums and Michaelmas Daisies presently should give the plants a can of liquid-manure now and then, and keep them securely staked and tied, but by no means budded or trussed up too tightly; the former must not be stopped any more now. A few of the most large-flowered kinds, planted at the foot of, and next to a warm wall, afford a cosmopolitan and very pleasing feature; care must be taken, however, to keep the soil well watered, and the foliage frequently syringed in hot, dry weather, or the plants will become smothered with thrips and red-spider, and never do much good. Chloëas Primroses must be shifted on into flowering pots as soon as possible now; keep them moderately close to a frame or pit for a week afterwards, then ventilate as freely as possible. Light shade is better than no shade. Any old plants that have been kept over from last winter should also be partly shaken out and potted into slightly larger sizes, or if the soil and roots are in good condition they may be merely shifted out, and vigorous examples to 7-inch or 8-inch pots will make very fine specimens by Christmas time or before. Sow seeds of Cinerarias and herbaceous Calceolarias at once, and keep the pans or boxes cool, shady, and moist. B. C. K.

THE COMING WEEK'S WORK.

Extracts from a garden diary from August 5th to August 12th.

Thinned and tied Dahlia. A good deal of attention is required now to produce good blooms. The best varieties for outting are the Cactus and Pom-pom. The stakes do not last long, and the large doubles are too heavy. Put in Hollyhock outtings. Healthy side shoots cut into single joints make good outtings, and many of them will strike under glass if kept close and shaded. An occasional dewing over should be given to keep the layer black and on the surface moist. Where many Carnations are required for cutting I find the advantage of planting out the tree or perpetual varieties. Seedlings from these throw a lot of bloom, and continue to flower a long time, and, if lifted in autumn, potted and placed in heat, the late buds will all open. Put in outtings of Pansies and Violets. There comes the young shoots coming in the nursery of the plants now, some of which may be pulled up with roots attached. I always make a special bed for these in a frame. The soil is made rather sandy, and lightened with some sifted leaf-mould. Potted Freesias and Roman Hyacinths. The latter are plunged over the top in Cocoa-fibre, but the Freesias are better exposed, as deep covering weakens the growth. Sowed more Mignonette in pots for blooming in winter. It is very important that the soil be made firm in the pots. This makes the growth dwarf and sturdy. The pots have been placed in a cold frame, though they would do very well exposed, except in the possible event of heavy rains falling. Repotted the collection of forced Roses. All did not require shifting, but those not repotted were top-dressed with loam and manure. Some of the old soil was removed from the surface, and the new soil rammed down very firm. After putting the plants in a cold bed. What little pruning was required was done before the potting. Top-dressing took place. I have occasionally used a little bone-meal in the soil, and a layer of half-inch bones on the top of the drainage is a great help where the plants are not repotted annually. Busy among the Chrysanthemums disbudding, tying the buds, &c. Those who are fond of these flowers find the long lines of plants, the stakes tied to wires to prevent the wind blowing them over, very interesting. I saw one growing a thousand, and, I confess, I spend a good deal of time among them without weariness. The trouble with earwigs has been considerable, as no quarter must be given, or many of the bedding-plants will scarcely have a good bloom. Some kinds, usually those which are robust in habit, seem to escape the attacks of these insects. The evening is the best time to search for them, when they are feeding. I take a candle and lantern about nine o'clock and pick them off when feeding. They seem less alert than I expected. I planted six geraniums, many of the forced plants were potted with the view of getting an autumn crop, and many of these are now in bloom. Some of the earliest-planted plants will ripen the fruit in the open air, others will be lifted and taken into a light house. A good many dahias are usually gathered, and the fruit is of good flavour, much better than those forced early in spring.

4206.—Grubs in a garden.—I imagine from your description that the Carrots and Onions were attacked by the grubs of the Daddy Long-legs or Crane-fly, which are commonly known by the name of Leather-jackets. Sand soaked in paraffin-oil might be of some use laid round the plants, or the grubs might be trapped by burying pieces of Turnips, Carrots, or Potatoes, and examining them every morning. A small skewer should be stuck into each to show where they are buried. If pieces of turf, stake, or board be laid about the grubs will often creep under them.—G. S. S.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with equally good results.

INDOOR PLANTS.

BEAUTIFUL LEAVES.

ABOVE all things powerful in the great laboratory of Nature we must give the place of honour to the green leaves of the meadow or forest, or the gardens of the world. Some people prefer flowers, but we may agree most cordially with Scotia's anient matron, who, on being closely questioned as to her maternal preference for one of her two handsome boys, settled the matter iconoclastically by saying "haith's best." And so, were we closely tied to a preference between leaves and flowers, we should agree with the wise woman of Edina; but if still more severely cross-examined, we should then revert to first principles and decide in favour of green or beautiful leaves. Our illustration of stove or hot-house foliage will speak for itself. As a choicest bit of leafy portraiture and of wood engraving you may compare it with "Bewick's Birds," since the principles are the same, white on black, and not black on white, being the true and natural function of the wood engraver's art. In the woodcuts of to-day we look

Aspidium, or can it be Davallia Mooreana? Whatever it is, it is well placed and beautiful in the group to which it belongs. What the flower is below is not so very easy to decide. It may be a Maranto, but one leans towards its being the brilliant Scutellaria Mocciniana, or perhaps an Aphelandra of the Leopoldi type. Whatever it may have been, it no doubt added to the green, grey, and bronzy tints above and around it, and whenever we see a beautiful group of this kind so varied in form and aspect we instinctively long for the day when the exquisite tints and colours as seen reversed in the camera shall be possible of reproduction by the negative. Then, and then only, will the triumph of the great Daguerre and the other inventors of photography be complete. As it is, no one can look upon the exquisite results now obtained by the camera and the graver without much inward satisfaction and content, especially as applied to the illustration of our garden vegetation and its friends and foes. B.

Raising seedlings.—Every amateur is not so successful in growing seedlings of good quality as "W. Cotton" appears to be. I once

pots. Rich, open soil is the most suitable. Pot firmly to obtain compact growth, and to gain colour grow the plants in a light house, near the glass.—E. H.

— These plants invariably flower after growing a certain distance, and especially so in a high temperature and comparatively dry atmosphere. The way to prevent their doing so is to pinch out the points of the shoots beyond the second or third pair of leaves frequently, and then with rich soil, plenty of water, a little liquid-manure once or twice a week, and a nice, moist atmosphere, they will develop fine, large, and handsome leaves. The last stoppings should be given five or six weeks before the plants are required to be at their best. Specimen Coleuses are usually shifted on into 8-inch or 9-inch pots. Larger sizes are sometimes employed, but in many instances the use of larger pots than those of 9 inches across is prohibited. Good sandy or turfy loam, mixed with a third of leaf-mould and plenty of sharp sand forms about the best compost. If the loam is at all heavy a little peat may be added.—B. C. R.

4231.—**Winter flowers.**—Very few plants, Christmas Roses, Camellias, common Primroses, and Violets, perhaps excepted, will flower at all freely during the winter in so low a temperature as 40 degs. Chinese Primulas, single and double, with P. obovata, are about the best plants for a cool-house, but even these would do much better with 5 degs. more warmth. In a temperature of 45 degs. to 55 degs. the above, with Cinerarias, Cyclamens, Zonal Pelargoniums, Heliotropes, Abutilons, Bouvardias, and others would do well.—B. C. R.

4245.—**Arum Lilies for Christmas and Easter.**—Toward the end of September pot up the plants in a compost of three parts loam to one of partly-decayed horse manure. Do not employ pots larger than is necessary to get the roots in. Those plants with a single crown should go into 8-inch pots, the largest into those 10 inches in diameter. Do not fill the pots too full with soil. Allow quite an inch of space for the small pots, and 2 inches for the larger for water, as this Lily enjoys copious supplies of moisture at the roots. Stand the plants at the back of a north wall for ten days or so until the roots have taken to the new soil; in this position the necessity of shading the glass is dispensed with as the leaves are certain to flag if the plants are placed in the greenhouse directly they are lifted from the open ground, consequent on the check the roots receive in lifting the plants. If the foliage is syringed twice, or even thrice a day during hot weather the plants will sooner get over the check. Place them in the greenhouse, choosing the lightest position, so that the foliage will not become drawn up weakly, which is often caused by standing the pots too close together. When the pots are full of new roots commence to feed them by the aid of liquid-manure, given every alternate watering, with an occasional handful of soot thrown into the water and well stirred. If liquid-manure can be had, half a teaspoonful of Clay's fertilizer sprinkled on the surface weekly, watering it in, will be of immense service to the plants. The growth is this year being quickly made on the young plants; early blooms may, therefore, be expected, and if the plants are regularly fed, and are given space, they will flower from Christmas to Easter.—S. P.

— You cannot expect these plants to open their blossoms properly at mid-winter in a temperature of 40 degs. only; they require a warmth of 55 degs. to 65 degs. at least to do so either at Christmas or Easter, unless the weather is abnormally fine and warm. The plants now in the ground must be kept regularly moist at the root; lift and pot them at the end of September, and take them into the greenhouse, but if you want early blossoms you must have more heat.—B. C. R.

— It is no use for you to think of it; to attempt to flower Arums so early without forcing is worse than to make bricks without straw.—A. G. BUTLER.

— Forty degrees is rather a low temperature to have Arum Lilies in bloom by Christmas, but you may succeed with the strongest plants if they are potted up early in September. There will be no difficulty about a supply at Easter.—E. H.

4234.—**Plants for a southeast conservatory.**—This is about the best aspect that could be mentioned, at least, for flowering plants—and in such a comparatively pure

Stove foliage. Engraved from a photograph sent by Mr. Tabor, North street, Ashford.

for portraiture, and in this instance we find it readily, and without any difficulty recognise several old friends. Bottom corner to left Anthurium crystallinum, to right of which is Lomaria gibba, one of our handsomest and most distinct of sub-arboreal stove Ferns. It really might be Brazeia insignis or Cyca revoluta in a small state, but as merely judging from the engraving I should at once say it is the Lomaria. Above the Fern, to the right, we have the massive shield-like leafage of Alocasia metallica, one of the most distinct of all the species of a remarkable group. Some of us remember the sensation caused in gardening circles and at the floral exhibitions when its metallic-hued leaves were first seen. Now-a-days it is but too often totally neglected in favour of newer and less worthy things. As well grown in small pots of rich compost, this metallic Alocasia is one of the plants to grow in a tiny stove. The pale Fern above, with its great pinnate fronds, is quite as distinct in its way as is the Areid. It is Polypodium aureum, its leafy surface of a pleasing grey-green or glaucous tint, its specific name being derived from the golden sori which display themselves beneath its ample fronds. In the top left hand corner is a Croton of the C. pictum type, and beneath a few great fronds of an Alsophila or

obtained "Geranium" seed from two large reliable growers. I had about a hundred plants. As they bloomed they were one after another thrown to the manure-heap as worthless; only four did I think worth pot room, and only one an improvement upon kinds I had before. This last is good everywhere, and in winter as well as summer. In a collection of "Geraniums" it looks well and attracts attention. I have also grown plants from seed of my own sowing with a like result, both from Zonale and Ivy-leaved "Geraniums." It is a rare thing to get one that in habit, colour, size, and freeness of flowering is better than its parent. I do not wish to discourage any attempt to improve existing kinds, but unless one has plenty of room, time, and patience, one is sure to get plenty of disappointment as well. The above is my experience with "Geraniums." With several other florists' flowers I have been more successful.—FLORIST.

4226.—**Coleus flowering.**—These plants do not flower much till they get pot-bound, and if the flower-spikes on their first appearance are pinched out there will be no blossom, and the young shoots that break out will fill up and give symmetry to the plants. Nice specimens may be grown in 10-inch pots, and very large plants may be had in 10-inch

atmosphere any of the ordinary run of greenhouse plants, such as Pelargoniums (Geraniums) of all kinds, Petunias, Fuchsias, tuberous-rooted Begonias, etc., ought to flourish and thrive excellently. If they do not, there must be some grave fault in the treatment. You cannot, however, expect to exceed with the above or any greenhouse plants, unless regular care and attention is bestowed upon them—these are absolutely indispensable under any circumstances, and it is chiefly through neglect in some form that so many failures occur. Pot plants must be attended to—as regards watering, shading, etc.—just when and as often as they require it, and not merely when you have the time or inclination to do it. A collection of good named kinds of "Geraniums" (Zonal Pelargoniums) would require comparatively little care, and a selection of the Ivy-leaved varieties, which do not seem to feel the want of water for a day or two, and are now extremely showy—even less. Again, a Vine trained over the roof, with perhaps a few Ferns, Palms, Aspidistras in pots growing beneath, would not call for very close attention. The most accommodating subjects of all, however, are Cacti and other succulents, which will often do without water for weeks together.—B. C. R.

You cannot expect to do much good without care and attention. For the walls the least troublesome creepers would be *Plumbago capensis*, *Fuchsias*, Ivy, *Geraniums*, *Habenaria elegans*, *Cacti*, *Hex Begonias*, *Pet. Fuchsias*, *Abutilons*, *Pelargoniums*, *Sparmannias*, *Hellebores*, *Gastias*, and many other things will do well with attention to watering on the staging.—A. G. BULLAN.

4232.—Seeds of "Geraniums" and *Fuchsias*.—Gather the seeds of the former as soon as they begin to turn brown, the seeds themselves being situated between the calyx of the flowers, at the base of the long spike or "bill," to which they are attached by means of a feathery appendage, which curls up when the seed is ripe, and is furnished with a row of silvery hairs. It left so long as this on the plant some are, however, liable to be lost, so it is best to gather them, stalks and all, before the seeds begin to part from the "beak," and lay them on paper in a dry and sunny place until fully ripe. The seed of *Fuchsias* is contained in a berry which follows the flower, and when these turn of a deep-purple or blackish colour, and become soft, they should be gathered, and the seed be picked out, or rubbed out gently in fine silver-sand. The early spring is the best time to sow in both cases, placing the seed in well-drained pots or pans of sandy loam or leaf-mould. If started about the middle of February in a genial temperature of 60 degs. to 70 degs., nearly, if not quite all the plants will flower the same year if kept growing on steadily. If there is no forcing-house or hot-bed, sow the seeds in an ordinary greenhouse or sunny window in May or June, and the plants will flower the following summer.—B. C. R.

4102.—Preserving *Ros. Savvs*.—The petals should be those of red *Roses*, or pink; white petals are not considered so good for the purpose. These petals, picked before they fall, should be placed in a paper tray in a window (where they will not, however, blow away) until they are rather dry, when they may be laid in a jar or basin, with alternate layers of bay-salt sprinkled over them. The petals of *Orange-flowers*, *Jasmines*, *Tuberose*, and many other sweet-smelling flowers can be added with advantage, and a little *Orris-root* and other spices improve the scent of the whole. The leaves of the *Bay-tree*, *Lemon Verbena*, *Mint*, *Rosemary*, *Thyme*, and *Lavender-herbs* are a nice addition, only requiring to be dried a little before they are added to the pot-pourri. This can be added to any time; bay-salt in proportion (i.e., a light sprinkling to a layer of leaves), being also mixed with the dried petals and leaves. Pot-pourri should be kept covered, except when it is needed to scent the room. A little of it, burned on a hot coal or two, in the fire-chimney, gives a delicious odour.—I. L. R.

4114.—Destroying cockroaches.—There is a powder sold for this purpose which is spread on the floor of the place which is infested with these pests, killing them by hundreds, though it does not affect cats and dogs. Cockroach traps, too, are useful if constantly kept baited and emptied every morning, and by means of these two things it is not difficult to lessen the plague considerably. Unfortunately, as soon as this is accomplished

the traps are apt to be forgotten and the powder no longer strewed, consequently, the cockroaches, which increase very rapidly, soon get ahead again. The only way to thoroughly clear them out is to keep up the fight until none have been caught for at least a week; this is much less trouble, and more economical in the long run than having to go through the same process at intervals continually.—I. L. R.

—Have you tried paraffin-oil? This is a very good destructive thing for ants, and a few other ways may also be adopted, which you apparently have not tried. A good plan is to put an inverted garden-pot over the nest. The ants will find their way into this receptacle, which may be lifted in a few days with a spade. Summersion in boiling water will effect the desired end. Dust sulphur about the place afterwards, which is a very good preventive, as they do not seem to care for this material.—C. T.

THE KITCHEN GARDEN.

PREPARING CUCUMBERS FOR WINTER.

For the successful growth of winter Cucumbers, for which preparations should be made in August, it is very essential that the structure be efficiently provided with both top and bottom-heat and also be well exposed to the light. Given the above conditions, the production of Cucumbers during the winter months is reduced to a minimum. The above class of structure is in marked contrast to that which is dark through too much timber being in the roof, and also indifferently provided with piping, or where the pits are low down and flat, and which in years gone by were looked upon as the ideal structures for the growth of Cucumbers. During the summer months Cucumbers might be grown under such conditions, but a supply during the winter months could not be maintained. Happily, such structures, in the majority of instances, are being swept away and replaced by those of more modern construction. Maintaining a supply during the early part of the winter can be managed easily enough. The mistake generally is that the plants are made to produce far more fruits than are at all necessary. Overburdening the plants in the earlier stages of their growth seriously cripples them and hinders the production of fruits during the later winter months, or nay from Christmas onwards, the period at which

wards the end of October or early in November to produce fruits from the end of January and through February, the time when winter Cucumbers are at a discount. By this time the early-fruited plants will be giving out if they have been at all closely cropped, when they may be either cleared away or go through a course of renovation, so as to recuperate their energies. The soil for winter Cucumbers must be lighter than is needful for summer growth, as the roots must be kept working freely. Three parts light loam to one each of well pulverised horse-manure and leaf-soil, with the usual correctives of old lime rubbish and pounded charcoal, more or less according to the texture of the loam, form a good mixture. By pulverised manure it must be understood that I refer to manure prepared as if for Mushrooms and rubbed through a sieve.

A GENIAL root-run is what is needed, and which must be provided if the plants are to do well, although suitable soil alone will not secure this if other conditions are not present to enable this to be made available for the roots to work freely. To illustrate my meaning, the soil is often placed direct on to the bricks, which are arranged around and above the pipes, so that the bottom-heat applied may have free access without any obstruction. Such practice must have a tendency to cause the soil which comes in contact with the bricks to become very dry. Now, to counteract this evil, it is much the best system before putting in the soil to spread a layer of prepared stable litter, or what would be better, litter and good leaves in equal parts, directly over the bricks. This will form a genial medium for the roots. The soil should be formed in hillocks at a distance of 3 feet apart, but before placing this direct on to the litter, a layer of turves, if available, should first be placed over the surface, thus forming a good foundation for the roots. Turves certainly are not absolutely necessary, and there are, no doubt, thousands of winter Cucumbers grown without them, but in such a case as this the hillocks of soil must be a deal larger than would be otherwise necessary, where turves are used. Healthy plants which have not been allowed to become pot-bound before planting will soon start freely into growth. A close and stuffy atmosphere will not build up a sturdy growth; consequently, this must be avoided, and the growths must be trained thinly. This, with a judicious admission of fresh air, will impart the desired solidity to ensure an after fruitful condition. The mistake which is generally made is allowing growths to ramble too much before stopping them, but the main laterals being disposed, the side or fruit-bearing ones should be stopped at one joint beyond the fruit, as when two, three, or even more are left the growth soon becomes a crowded mass; consequently a wholesale thinning out of the shoots has to be resorted to, this seriously checking the fruit-bearing capabilities of the plants. The thinning-out should be continually and gradually taking place, removing a few of the larger leaves and diseased growth to enable the light to have free access to the young extending shoots, which must be kept laid in, as it must be remembered that growth must never be at a standstill. The water should not be at a lower temperature than 80 degs.—even 85 degs. would be better. As the roots extend to the outside of the hillocks, a slight top-dressing must be given. Heavy top-dressings are not needed, as the roots do not take so freely as when about half an inch of the material is applied; little and often is the best course to pursue, as then the main feeders are kept in an active condition. As the hillocks become permeated with roots the mistake must not be made of applying strong liquid, but if this is applied in a diluted or clarified form the plants will derive marked benefit. The growth which is taking place is altogether slower, on account of the short and, I might say, almost useless days, so it will be readily understood that to gorge the roots with stronger food than they can assimilate must end in failure, the leaves quickly turning to a sickly yellow. A temperature of 65 degs. or even 70 degs. on mild nights will impart a steady growth, with a rise of 5 degs. by day by artificial heat. A low stagnant atmosphere is a sure source of mildew. It is a very unwise proceeding to allow all fruits to remain whole form. Only sufficient should

Section of winter Cucumber-house. (See page 317.)

they are most in demand. The general rule in gardens is to raise the plants sufficiently early, so as to enable them to be planted during September, the reason given being that it is very essential that they be well established or in a condition for bearing fruit before the short days arrive. Such treatment certainly is very rational, but where there is sufficient space an extra batch should be held over for planting to

be allowed to form to keep up a regular supply, a glut at any time being avoided. The system of ventilation as usually accorded to Cucumbers is often called in question. If I entered a Cucumber-house on a mild day during the winter and found it close and stuffy, I should apply a little ventilation, but, on the other hand, during a very cold or sunless period I should not put on ventilation just for the sake of so doing, as sufficient air for all practical purposes would be obtained through the laps of the glass. During the earlier stages of growth, ventilation carefully, or rather judiciously, applied would impart to the growth that solidity which is so necessary for an after fruitful growth. A good form of lean-to house for winter Cucumbers is illustrated on page 316. A.

To renovate a worn-out Cucumber-bed.—First remove all the decayed and unhealthy leaves. Next cover the whole surface of the bed and all the Cucumber growth except the healthy leaves, and cover the ends of the shoots 2 inches in depth with rotten manure. If this is not to be had, use garden soil and horse-droppings in equal quantities. Syringe twice a day in bright weather. Keep close on cloudy days. As the season advances, give but little air even when the sun shines, remembering that the two main requisites for success in Cucumber growing are heat and moisture. Never mind about giving air as long as the temperature can be kept up to a high standard. We are often told in GARDENING that air-giving is not essential to successful Cucumber culture. When the nights become cold, put mats over the lights. If the above directions are followed, new life can be put into the bed, and it can be kept into bearing till late in the season.—L. O. K.

4243.—Potato-Onions, &c.—The botanical name of the Potato-Onion is *Allium Cepa* var. *aggregatum*, a very useful sort to grow; the bulbs are ready for use before any other kind, and keep plump a long time after they are stored, when lifted in good condition. This Onion is not raised from seed, but treated like Shallots; the bulbs of last year's growth are planted early in February, about 3 inches deep. When the soil is rich and has been well managed the bulbs produce a quantity of offsets and swell to a large size. When ripe, which is easily ascertained by the tops changing colour, the roots should be lifted and laid in a dry place to ensure the bulbs being thoroughly fit for storing in a cool room free from frost. As to cropping a vegetable garden, much may be done at this time of the year to ensure success throughout the winter and spring. Now is a good time to sow a pinch of seed of Ellam's Early and Flower of Spring Cabbages. The first named is by far the earliest to come to perfection, while the second is a capital sort for giving good heads after Ellam's is past and gone. A small sowing of Nantes' Horn Carrot on a warm border will produce a crop of useful roots. Tripoli Onions should be sown about the middle of August; these are ready for use, either for drawing in a green state in the autumn or for early bulbs in the spring. Spinach is much valued by some persons. Sow at the same time as the autumn Onions a pinch of the round-seeded or perpetual variety. It is not yet too late to put out a batch of late Celery plants, provided the latter can be secured; this crop succeeds as well planted in a double or even triple row if land is scarce. If procurable, late sorts of Broccoli, Winter Kale, or Savoys may still be planted with a fair prospect of success. A pinch of Cauliflower seed should be sown at the end of August with a view to saving the plants in a cold frame over the winter; these would succeed the late Broccoli. Where winter salads are appreciated the middle of August is a seasonable time to sow a pinch of both Lettuce and Endive. Black-seeded Bath and Hammermith are the best kinds of Cos and Cabbage respectively. Of the latter Incomparable Green is the best; of the Moss-curl and Round-leaved Batevian is to be preferred as a Large-leaved Endive.—S. P.

The small tubers or offsets should be planted as early as possible in the opening in the Southern counties, where the soil is light and warm. They are usually planted about Christmas-time, when they will be ripe and fit to harvest by the end of June. At the present time work in the vegetable garden

principally consists of getting in winter Greens of various kinds, such as Savoys, Broccoli, Kale, &c., sowing Turnips and Spinach, also Onions to stand the winter; Cabbages, too, should be sown at once, and Cauliflowers about the third week in August.—B. C. R.

TREES AND SHRUBS.

GOLDEN-LEAVED TREES.

WHATEVER may be said to the contrary, there can be no doubt that when planted with discretion and in well-chosen positions, trees with

Golden Yew (*Taxus baccata aurea*).

golden foliage are capable of producing some of the most pleasing and varied effects in the landscape, that without their use it would be almost impossible to bring about. I am not now referring to the many sickly, parti-coloured trees and shrubs that are now so widely cultivated, but to the more healthy and vigorous growing section, where fine, sturdy specimens on their own roots are to be found. The effect produced by clumps of the golden Elder, jutting out here and there with bigger masses of some of the more pendent-branched Willows in an old-fashioned garden in the South of England will not be easily forgotten, for the thought at once occurred to me what pleasing and charming combinations were capable of bringing about by wise discrimination in the use of golden-leaved trees and shrubs. A well-developed specimen of, say, the variegated-leaved Sycamore when suitably planted is capable of imparting a particular line of beauty to the position in which it is growing. Then there are some of the silvery-leaved Maples that are curiously beautiful if happily placed with regard to their surroundings. But to return to the golden Conifers, which constitute a distinct branch of trees and shrubs with parti-coloured foliage; we have several that are full of interest and of great value for the contrast they afford to the general run of our green-leaved kinds. The golden variety of the Chinese Juniper (*Juniperus chinensis aurea*) has, perhaps, no rival amongst trees of its kind, the depth of tint, which only seems to be augmented by the heat of summer, being pronounced and pleasing. Then *Retinospora plumosa aurea*, *R. obtusa aurea*, and *R. pisifera aurea*, are all worthy of cultivation, the colour of foliage being rich and constant. *Thuja occidentalis aurea* and *Cupressus Lawsoniana lutea* are also well worthy of note, and when well placed they are distinct and effective. Even the golden-leaved form of the Highland Pine (*Pinus sylvestris aurea*) has a charm of its own, and is always a welcome tree when growing in the shrubbery or woodland. Of our common Spruce Fir there is a very pretty and distinct

golden variety in *Abies excelsa aurea*, the bright bronzy-yellow of the young growths rendering it a tree of surpassing beauty. These, with the Golden Yew (*Taxus baccata aurea*)—see note—are the best of the Conifers that come under the about class now being noticed, and when they are judiciously planted and have formed fairly-sized specimens, their beauty is certainly very unusual and not to be despised. A.

The Venetian Sumach (*Rhus Cotinus*).

—An old-fashioned, but none the less handsome shrub is this *Rhus*, which, ornamental at all seasons, is especially so when crowned with its fastery inflorescence towards the latter part of the summer, in which stage it remains for some time, and again in the autumn by reason of the vivid tints assumed by the leaves before they drop. The colour acquired by the decaying foliage will depend to a considerable extent upon the position of the plant, as if in a somewhat dry and exposed spot, the leaves are much more richly coloured than is the case where the plant is in a situation more conducive to rapid growth. Few (if any) shrubs are more suited to plant as an isolated specimen on Grass than this, as it will form a well-balanced bush, totally devoid of any stiffness or formality, and the lowermost branches will extend for some little distance from the parent plant—not far, it is true, but quite sufficient to form a desirable edging to the central mass. I was never so much struck with the beauty of this *Rhus* as on one occasion when I unexpectedly came upon a fine specimen just at its best, whose bright-red, wig-like masses of inflorescence were lit up by the rays of the declining sun and formed a beautiful summer picture.—H.

***Spiraea arifolia*.**—This is a lovely July-flowering shrub. It should be placed, if possible, by itself, as when crowded amongst other things its distinctive character is lost. In midsummer its graceful branches are bent with the weight of paucules of creamy-white flowers, which are produced in rich profusion. Where the garden is of sufficient size, it should be planted on the outskirts of the lawn, and the effect of its bold, free, and handsome character is enhanced by the green groundwork, so to speak. It is a North American shrub, and grows about 6 feet in height, requiring ordinary garden soil, but well drained, and a fairly open position. The *Spiraeas*, although exceedingly beautiful, are not seen half enough of in either large or medium-sized gardens.—V. C.

4246.—Pruning hedges.—Your gardener is right so far as to cutting the hedges early, they then went to be pruned again. When there is only time enough to clip hedges once a year they are generally left until the early part of the month of August. It is usual, however, to go over hedges that are connected with the garden or pleasure grounds twice a year, which, of course, adds to the labour. I hardly understand what you mean by there being a lot of old wood on your Rose-trees. If this growth was not cut back pretty hard in the winter, of course there would be that. The great heat has nothing to do with it. It appears to me that there is a difference of opinion between you and your gardener as to how Roses should be pruned, one preferring them to be cut back hard, and the other much less severely. If they are grown as dwarf plants I think the latter plan the best, which when skillfully pruned do not show much of the old wood in summer. The information sent is not, however, sufficiently clear to give a more definite answer.—J. C. C.

The gardener is not altogether wrong as regards the hedges. If cut early they will require cutting again; but, on the other hand, if delayed too long the bottom leaves will die and the Privet hedges will be brown instead of green. Have them cut at once, and to keep the hedges in good order they should be cut twice a year. If the Roses had been cut back fairly hard there would not have been any dead wood, dry though the season has been; but some people do not agree with much cutting back. However, they will have to be cut pretty hard in the next season to get the bottoms well furnished. Dead wood should be removed at once.—E. H.

Both Privet and Quick-hedges should be cut at least twice a year—indeed, they are all the better if they are cut even oftener than that. By constant clipping of the shoots more growths are made, the hedge gradually becomes thicker

and, of course, a better fence both in bulk and appearance. I commence to cut these hedges when the shoots are 6 inches long, and as often as they require it after they are out. I know it takes up time, but if good and neat hedges are an object this cannot be avoided. If the Rose-trees were replanted this spring, the hoed end drought would account for the dead wood in them, but if not it was caused by the frost of last winter, and should have been cut out when pruning in March or April of this year.—S. P.

— Your gardener's excuse is a poor one. Cut back at once. The hedge will be all the thicker. As for the roses, heat will not make young wood old. The effect it had on my Roses was to retard the growth of the new wood, and to force a quantity of bloom, which lasted only a few hours.—A. G. BULLER.

4223.—Rhododendrons in a clayey loam.—Yes, all the more vigorous varieties at any rate will succeed excellently in such a soil as you describe, with a little care in preparing the sites. The drainage must be good, and a moderate quantity of either peat or good leaf-mould, with, if possible, some sand also, must be worked in round each plant before it is put in place. Keep the collars high, and with a due supply of moisture all will go well.—B. C. R.

— A good deal depends upon what forms the basis of the clay. If there is any chalk Rhododendrons will not thrive in it, but a heavy loam over the old red sandstone is not bad for Rhododendrons. With the addition of leaf-mould it may be made quite suitable.—E. H.

— If you mix a quantity of peat with the soil you may succeed in growing Rhododendrons, but in clayey loam alone you cannot hope to be successful. Fibrous loam, with an admixture of well-decayed manure, will grow these plants.—A. G. BULLER.

— I should think that the Rhododendrons would succeed. Mr. Anthony Waterer, whose opinion is worth much in respect to this class of plants, mentions that all the American plants may be said to delight in, and to require, what is called peat-soil. It was at one time believed that they would not thrive in any other. Experience, however, proves the contrary, and it is now proved that Rhododendrons, the most important of them all, as well as others of the more vigorous-habited plants, succeed in almost any soil that does not contain lime. In many sandy loams they grow with as much vigour and luxuriance as they do in peat; in fact, almost any loamy soil free from lime or chalk may be rendered suitable for them by a liberal admixture of leaf-mould or any fibrous material, such as the parings of pasture land. When the soil is poor, cow-dung in a thoroughly decayed state proves one of the best manures for these plants. You cannot have better advice than this.—C. T.

HARDY PERIWINKLES.

THERE are very few gardens where a place cannot be found for some of the Periwinkles, for among their other desirable qualities is that of thriving in situations where few plants of a shrubby nature can be induced to flourish, and from their low-growing character, combined with the fact that the foliage is retained throughout the winter, they are bright and cheerful at all seasons, and are very useful for clothing spots where little else but the Ivy will thrive. For covering sloping banks or positions such as this the different Periwinkles are well suited, and they (the minor kind especially) will carpet the ground with a dense mass of slender twigs, clothed with ovate deep-green leaves, among which the pretty blue, white, or violet-coloured blossoms may be found nodding for months together, as a succession of blooms is kept up for a considerable period. The two variegated varieties with respectively white and yellow marked leaves are also very pretty, and when interspersed to a limited extent among plants of the normal hue the variegated portions stand out markedly by contrast with their surroundings. The larger Periwinkle (major) will cover a given space in much less time than its smaller relative, and is suitable for planting under much the same conditions as that is. Where there is a bank too steep for plants to be grown on the sides thereof, the larger Periwinkle is one of those that may be planted along the top, and allowed to hang over and furnish what otherwise might be a bare and unsightly spot. Of course the shoots of some of the more vigorous climbing plants will depend for a much greater distance than even the strongest Periwinkles, but they list afford a pleasing variety, as well as being suited for shady spots. The variegated form of

this has the leaves irregularly, but clearly marked with white, and taken altogether is one of the very best of low-growing hardy plants with variegated foliage. I once saw a dunken walk through a shady part of the garden flanked on either side by the different Periwinkles, and a very pretty effect was produced thereby, the walk being about a couple of feet below the level of the surrounding ground. T.

ORCHIDS.

CATLEYA REX.

THE first flower of this splendid member of the Labiatae section of this genus which I have ever had the good fortune to see, comes to hand from "R. C. F.," living in the County of Sussex. The flower appears to be somewhat small in size; but this is explained by "R. C. F.," who says it was a very small plant semi-established when he purchased it last May twelvemonth, and the flower sent is one of three produced upon the first bulb made by the plant, and he says he never expected it to flower so soon. Now, I have no knowledge of this Orchid, nor of its qualities, either as a free or a shy bloomer, never having seen it before, and I am proud to think that the first flower comes to me from a reader of GARDENING. This Cattleya is one of the recent introductions of M. Landon, of Brussels, who has kept its native habitat a secret, and which cannot be put down to anything but the exigencies of trade concerns, for it may be that he had spent a lot of money before his man found this plant, and he wants to recoup himself for some of the outlay, and some allowance must be made for this before blaming him for disclosing its habitat. All collectors try to do the same thing, and, as far as I can see, it is a very right thing, because traders have a very different battle to fight to the collector, who naturally enough wants to know where the habitat of every new thing is, because he has no losses and no expenditure in the matter. However, you have succeeded so far as to get it to bloom, and you cannot do better than to keep it under the same conditions as Cattleya labiata and Cattleya Warocqueana, shifting it from time to time should the plant not appear to be doing well; but when you have the plant in a spot which suits it there you should keep it; and if "R. C. F." has the two plants named in his collection, and has space for a few more he should invest in the Labiatae varieties, or the so-called varieties, and with the following kinds he always would have a display: Cattleya labiata, C. Mendeli, C. Mossii, C. Trianae, C. Dowiana, C. Perolviana, C. Warneri, C. euraea, C. Gaskelliana, C. speciosissima, C. Eldorado, and C. Warocqueana, and C. gigas. All of these have broken into many varieties, most of them from pure white flowers to flowers of the deepest hue, and of all of them named unflowered plants can be purchased at a low price, and from these you may have the chance to have a very fine variety crop out, which would be worth very much more than you would pay for the whole lot of plants. I shall be pleased another season to hear from you again, and if you have a larger flower to spare I should be obliged to you for it, as I want it for drying, and next season I feel sure you will have larger flowers. MATT. BRAMBLE.

VANDA BATEMANI.

THIS is an Orchid which I must tell "J. Acland" does not appear to me to be a suitable one for him. True, he has not told me the extent of his convenience or of his place, but simply asks if it is a good plant and worth his attention? This Vanda has been known for many years, having been first found by a French explorer between seventy and eighty years ago, and the celebrated Dutchman Blume rediscovered it, but it was not until about fifty years ago that our own countryman, Hugh Cummings, first sent the plant home in a living state, and it was first flowered in Europe by the gentleman whose name it bears, it having been dedicated to him by the famous Dr. Lindley; but it has also been called Stanouperia lissoclioides, Fieldia lissoclioides, and Vanda lissoclioides by various authors. The first generic name does not appear to me to have anything in it to distinguish it from Vanda, and the second one, Fieldia, dedicated to Baron Field, chief judge of

New South Wales, was already occupied by a greenish-white-flowered gesneriaceae plant which I used to grow some years ago, but which I have not seen for about thirty years, and as it is the only species in the genus it stands some chance of becoming extinct in our gardens, so that there does not appear to be much use in disturbing the present plant from Lindley's genus, whilst its original name of Lissoclium is said not to be appropriate, and so the plant stands with Lindley's own name, by which it was figured in the *Botanical Register* for 1846, t. 59, a name, I think, by which it will be best known by most of my friends in the gardens of this country. It appears to be very widely distributed throughout the Islands of the Indian Ocean, more especially those of the Philippine group, and on one of these it was found by Mr. John Veitch some years ago, growing in great abundance on the seashore quite close to the water. For this reason such plants would, I think, be benefited by being some seaweed put about on the surface of the soil, and so they would be if it were used beneath the stages; indeed, Mr. Sander used to adopt this system in his Orchid-house, and I think too it was attended with good results. Why Mr. Sander abandoned it I cannot say, unless it was that it was attended with too great an expense. However, this Vanda Batemani is quite a giant of its race. It grows from 6 feet to 12 feet or more high, with broad strap-shaped leaves, which are some 18 inches or 2 feet long, making the plant 3 feet or 4 feet across. They are thick and leathery in texture and pale-green, and it is on account of its great size, which takes up so much space, that I do not think, unless you have a large collection and plenty of space, that the plant is one you should take in hand; but if you have both at command this is a plant you ought by no means to be without. The size would add dignity to the collection, whilst its long and many-flowered racemes would add fresh zest to your Orchid growing. The flowers are some 3 inches across. They are produced in one or two dozens together, and they last in beauty for one or two months, or even more. The sepals and petals are plain purplish-crimson on the back side, and yellowish-buff in front, spotted and blotched with purple in front. The lip is three lobed, small, buff. The plant wants just some Sphagnum Moss to keep it firm and moist, good drainage, and plenty of heat and moisture in the air at all seasons. MATT. BRAMBLE.

MORMODES PARDINUM.

IT is strange how fine varieties of Orchids crop up, and how they fall into amateurs' hands who do not know them. Now here is a splendid kind sent me from Leeds by "M. J. H.," asking its name and anything I know of it, saying it is one of a lot he bought in a sale-room about two years ago, for which he paid two shillings and sixpence for a lot of little pieces, and he says he has about twenty kinds of Orchids, some of which he hopes soon to flower. I shall be glad to render him all the assistance I can to get the various kinds named. Well, here we have one of the best varieties of this plant that I have ever seen, the yellow is so rich, and the crimson spotting is so rich also, and so profuse, that it is certainly very showy, and when you get this plant to bloom freely with spikes a foot or more long, and carrying a dense, many-flowered raceme it will be a thing of beauty and a joy for several weeks together in the year. It is now about fifty-five years ago since this plant first flowered in the country, having been discovered in the Province of Oaxaca some two years previously, and I do not think our gardens have ever been without since. This belongs to a curious race of plants which I do not know. It has the appearance of one of the curious frocks that many have, and I only know of one plant that is credited with being a variety or perhaps a sub-variety, for it is only a colour variety, being quite destitute of the profusion of rich crimson spots that make your flowers so very beautiful, it is called peridium unicolor; it is of a clear, bright yellow, quite destitute of spotting of any kind, and, consequently, neither so showy or so interesting as the plant we now have under consideration. This plant comes from a tolerably warm spot in the Province of Oaxaca, and for this reason it will be well to grow it in the warm end of the Cattleya-house,

or even the East Indian-house, or the warmest stove, with a nice moist atmosphere. They should be well drained, and the plants must not be syringed much, because the water lies so frequently in the young growth, and spoils it from want of the activity in the atmosphere; but I like to maintain a heavy moisture in the air. About this time, when the plants are flowering, they also are growing, so that they are nicely furnished with leaves, which will help to set the flowers off to the best advantage. And the plants must be kept in their growing condition until the bulb is finished up. When this is accomplished water must be gradually diminished until the plant is left quite dry. During this time its leaves will have gradually turned yellow and fallen off, when they may be stood upon a shelf in a cool-house, where the thermometer does not fall lower than about 50 degs. Here they may be kept quite dry until about the middle of the month of February, when they will require shaking out of the old soil and repotting, using for them about equal parts of forty-loam and peat, from which the greater portion of the fine soil has been shaken. Drain the pots well and elevate them upon a little cone-like mound to enable the water to run freely away from the young growths.

MATT. BRANBLE.

A note on bedding plants.—One of the most useful of all bedding plants are the Tufted Pansies. The show and fancy classes are not so useful for the garden as this charming race, which is getting more largely grown each year. The word "tufted" is an allusion to their tufted growth, and there is a charming gradation of colours in the flowers. Ordinary soil, but slight shelter and shade are more agreeable to them than full exposure. Nothing suits the plants better than a steady, moist border where they are not exposed to the fierce rays of a summer sun. The cuttings strike readily when taken in August or September and placed in a cold frame. Dibble them in moderately thickly, and leave them there until the following April, when they should be put out in the positions they are to beautify. Any old lights will give adequate protection during the winter, and a few mats thrown on in periods of hard frosts. Water liberally in dry weather, and keep seed-vessels picked off to prolong the display of flowers. If seed is required then, of course, it must be saved. It should be sown in February in shallow pans, placed in gentle heat, and in the month of April prick off the seedlings into other pans, planting them out in May. A good display of flowers may be expected in August, whilst if the seed is sown in July in a cold frame, the plants will, if put out in the following spring, bloom in June. Avoid gaudy or fancy kinds, but select those of self colours, which are always more effective than those flowers marked or spotted with a variety of tints, like mosaic. The fine Double Stocks, the Brompton, and the Ten-week, familiar garden flowers, are delightful to plant in beds. A crimson variety for the centre and a white kind outside make a delightful contrast, and a whiff of fragrance is carried on the wind. To get a quick display, sow the seed in March, treating it exactly as suggested for half-hardy annuals, and another sowing early in May will ensure an acceptable succession. Harden them well before planting out, and on no account risk the plants in the open before May. The rock upon which amateurs split in the culture of the Stock is the watering. Unless great care is taken to keep the soil always moist, never dry, the Stocks receive a check, become stunted in growth, and then bloom prematurely. The bright blue *Salvia patens* is a charming plant to fill the centre of a vase, and is grown in the same way, practically, as the Fuchsia. We may also associate with it the free and graceful *Pentstemon*, *Verbena*, *Verbenas*, not forgetting the old *V. Veronica*, China Asters, Zinnias, and *Lantana* may also be mentioned, but in ordinary gardens a

selection will suffice. Choose such things that create colour, and are not difficult to grow, as the Fuchsia or the Tuberous Begonia.—V. C.

OUTDOOR PLANTS.

LILIUM LEICHTLINI.

This is one of the prettiest of the more uncommon Lilies, but one that is somewhat particular in its cultural requirements. The flowers of *L. Leichtlini* are of a pleasing shade of rather pale yellow, copiously spotted, especially towards the centre, with red, while the exterior of the bloom is prettily flushed with the same hue. The petals reflex after the manner of those of the Tiger Lilies, but no description can do justice to the manner they are poised on slender stems in so delicate a fashion that they are

times noticeable in *L. Leichtlini*, as well as in two or three other Lilies, is that when the flower-stem first starts into growth, it will, instead of growing at once in an upright manner, proceed underground for some little distance before making its appearance. This same curious feature is also very noticeable in the case of the Neigherry Lily (*L. neigherryense*). A Lily possessing many points in common with *L. Leichtlini*, but at the same time differing from it in several particulars, is that known under the names of *L. pseudo-tigrinum*, *L. jecundum*, and *L. Maximowiczii*, and, in addition, is frequently regarded as a variety of *L. tigrinum*. It is altogether a far more slender-growing plant than any of the Tiger Lilies, while another notable feature is the total absence of bulbils in the axils of the leaves, which form so prominent a feature in the case of *L. tigrinum*. The flowers of *L. Maximowiczii* are vermilion, spotted with black, and in shape a good deal like those of *L. Leichtlini*, but the flower-stalks are not quite so long and slender. H.

OUR READERS' ILLUSTRATIONS: *Liliium Leichtlini*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. A. D. Fort, Stoke Newington.

stirred by every breeze. Another feature, and that a very desirable one, in connection with the blooms is that they remain in perfection longer than those of most Lilies, and at no time do they fade after being open a few days, as some Lilies do. *L. Leichtlini* is one of the Lilies that are sent here from Japan during the winter months, but only in limited numbers, and as it is not a particularly good traveller, the bulbs do not always reach this country in a satisfactory condition. The bulbs are compact, flattened somewhat on the top, and bear a good deal of resemblance to those of *L. Batemanianae*; in fact, when thoroughly dormant, some bulbs cannot be distinguished therefrom, while, on the other hand, one may feel confident with regard to some of them. *L. Leichtlini* commences to grow earlier in the season than *L. Batemanianae*. It should be set in soil of a somewhat sandy nature, that, though thoroughly drained, is not dried up at all during the summer. A peculiarity some-

Iris Kämpferi.—A very beautiful summer flower is this Japanese Iris, which is seldom seen well grown in English gardens. The truth is that the plants require more moisture than is usually considered necessary, and will even live in water. Failure is the only possible result from plants not grown in a wet, loamy soil, but when in such a position a fine growth is made, set off in July by flowers of great breadth and splendid colour. The majority of the kinds are imported from Japan, and with each consignment also a drawing of the several kinds, so that the purchaser can tell what to expect. The flowers are very handsome when in either double or of bizarre colouring. The best kind are those of deep self hues, not marked, spotted, and flaked blooms, that are far less effectual and pleasing than the self shades. This is an important point. One of the finest forms is the pure white, which has a pleasing aspect by the side of a stream or lake. It is a pity that such flowers are not more grown in English gardens. It cannot be that there is no room, as in the majority of gardens no flower or plant life is to be seen by the margin of pond or lake, as the case may be, and it is exactly these places that need adornment. The Siberian Iris and its several forms, particularly the variety named *alba*, are great lovers of a moist soil, and, in truth, need moisture to keep them in good health.—C. T.

4220.—Flowers in a garden.—As regards the things to plant you cannot do better than get a good selection of bulbs. Read my notes on "Bulbous Plants" in last week's GARDENING, and the reply "A House Border," in July 22nd, page 287. You may plant all the things there mentioned in the autumn. Meanwhile, unless already done, I should advise you to get the ground in thorough order by trenching it, if it is crude and unwholesome—not an unusual state of things when the garden is fresh from the builder's hands. If very poor, it will pay to give the soil a heavy dressing of loam and manure, and if labels are used, they should be small; but in time you will get to know the plants, whether in leaf or flower. A great evil is disturbing the roots for the increase of stock or for the sake of making alterations until they have at least occupied the ground for five or six years. The majority of hardy plants never reach full beauty until about five years old, when division and a fresh site are beneficial to give them renewed strength. The two best seasons for planting are the autumn and spring, preferably early autumn, to give a long season for becoming established before frosts occur. In the spring they come up strongly in preparation for the annual manifestation of flowers; but when autumn has been missed, choose, say, March, growth then commencing.—C. T.

4221.—Fancy Pansies.—Fancy Pansies require just the same treatment as the old English type of Pansy, which may be

briefly stated thus: Prepare the beds early in September for autumn planting. If the soil is light add something of a heavier character, such as road-scrappings and heavy loam, with some two-year-old cow-manure. Work the soil up deeply, and leave it rough for the air to act upon it. Take the cuttings now. There are plenty of young shoots in the centre of the plants, some of which may probably be taken off with roots. Plant in a bed of sandy compost in a frame, or under a hand-light. For early flowering plant out in October. For later blooming take the cuttings in a month's time, or even later, keep under glass, but quite cool, all winter, and plant in March. Mulch and water are necessary in dry weather, and if very hot and dry when the plants are in bloom, if required for exhibition, shade for a few days before the show.—E. H.

— You will not experience great difficulty in growing these *Pansies*. You may sow seed at once, and propagate the seeds by cuttings. This will be by far the best plan, as then you are certain to get the kind true to name. The cuttings strike readily under a hand-glass, using light soil. Keep moist and slightly shaded. Select short, stobby shoots, which make the better plants. August and September are the best months for striking cuttings. Any good florist's catalogue will give you a list of the best kinds. The flowers must be round, smooth at the edge, velvety, firm, and the colour clear, varied, but the blotches must be large, well-defined, and the bedding regular. These are the rules judges go by. I do not care for this class myself. The Tufted *Pansies*, formerly known as *Violas*, are much better garden flowers.—C. T.

4225.—**Double Pyrethrums**—It is difficult to grow double or single *Pyrethrums* in a garden where slugs are troublesome, as they eat off the young growth just as it is coming through the soil in the spring. For the same reason it is not desirable to move or divide the plants when they are dormant. It is much safer to move them in the month of April or May, when they are in active growth, as they then quickly grow out of the way of the slugs. If you get seed from a good source you may raise some useful double varieties from it. There are, however, many very beautiful named ones to be had.—J. C. C.

— The cultivation of these charming plants is of the simplest. Once planted in any good garden soil, preferably of a light, loamy character, with free drainage, and they will flourish and bloom profusely for many years, only requiring to be divided and replanted when the clumps become too large. Spring is the best time to plant, whether young stock is purchased or home-grown plants are simply divided, towards the end of March or some time during April, according to the season, being the most suitable period. The ground should be made moderately rich with well decayed manure or leaf-soil, and a light dressing spread among the plants, and lightly forked in every autumn is very beneficial.—B. C. R.

— There is a long list of varieties and few bad kinds. Select those of decided colour, and the double white and double rose are very charming. This class is very hardy, and make a bright display in the garden, whilst the flowers produced very freely last a long time when gathered for the house. June is the month when they are in full perfection, but they continue to bloom more or less over a long season. As regards their culture they require very little. The time to propagate is in the spring, when they are commencing to grow, and a large, well-established mass will make several healthy plants. Ordinary soil will suffice, but it is better to get it rich, deep, and not too light. If too light the growth is weak and spindling, nor must the plants be in a shady position, as under these conditions the flower-stems are few and far between, and lanky. Plenty of sunshine, a deep soil, and a little attention to the plants when they are coming into bloom to prevent heavy winds and rains breaking down the masses of flowers, are the principal points for consideration.—C. T.

— These hardy perennials require no special treatment. Any good garden soil will grow them well. Put the young plants in the rows, plant in firm and watering well in. After they will take care of themselves until large enough to be taken up and pulled to pieces for multiplication.—A. G. BUTLER.

MAIZE OR INDIAN CORN (ZEA MAYS). This is one of the noblest of the Grasses that thrive in our climate, and it is an almost indispensable adornment to our gardens, where it has a fine appearance either in isolated masses or associated with other fine-leaved plants. *Cuzco nud* and *Caragua* (here figured) are the largest

Maize or Indian Corn (*Zea Mays* var. *Caragua*).

and finest of the green varieties, and gracillima the smallest and most useful. The variegated or Japanese Maize is a very handsome variety. Its beautiful variegation is reproduced true from seed. It is particularly useful for the outer margins of beds of sub-tropical plants and like positions, where its variegation may be well seen, and where its graceful leaves will prove effective. It should, in all cases, have light, rich, warm soil. It has a habit of breaking into shoots rather freely near the base of the central stem, and where it grows very freely this should recommend it for planting in an isolated manner, or in groups of three or five on the turf. The seeds of the Maize should be sown in a gentle hot-bed in April, although occasionally it will succeed if sown out-of-doors. Gradually harden off the plants before they have made more than three or four leaves, moving them to a cool frame very near the glass, so as to keep them stordy, finally exposing them in the same position by taking the lights quite off. This course is, perhaps, the more desirable in the case of the Variegated Maize, which does not grow so vigorously as the green kinds. In neither case should the plants be kept long in heat, for if thus treated they will not thrive so well. The first few leaves that the variegated kind makes are green, but they soon begin to manifest the variegation. The plants should be placed out-of-doors about the middle of May. G.

4250.—**Erigeron aurantiacus**.—I cannot understand how it is that this plant dies away so quickly with you. With me it grows vigorously in a rather rough but well drained soil. I think some insect must injure the roots, as I have seen it doing equally as well in other gardens as it does in mine. I have some plants just showing flower which I obtained from seed sown last September, and the plants wintered in the greenhouse. Try a layer of coal ashes, mixed with a little soot, round the collar of the plants.—J. C. C.

— Take up the old roots the first week in October, pull them in pieces, and plant in sandy soil in a cold frame. Do not make them too small, rather give them too much water during the winter. To prevent the roots rotting, give a moderate amount of air on all favourable occasions. If the weather be tolerably mild about the

middle of March plant out where they are to flower. Should the weather be hot and dry keep the soil about them moist. No difficulty should be experienced in getting this herbaceous plant to flourish in a border facing either south or inclined to the east.—S. P.

4240.—**Planting Christmas Roses**.—Moderate sized plants will move safely in October (not earlier), but when lifted for division the best time is just as they are on the point of starting into growth in spring. Work plenty of old leaf-mould or manure into the ground.—E. H.

ROSES.

4220.—**Roses in borders**.—China Roses are, perhaps, the hardiest and most continuous bloomers that are suitable for your purpose, but, unfortunately, they are rather of small growth. They are, however, very beautiful, and, for the most part, fragrant. Archduke Charles, Ducber, Cramoisis, Supérieure, Fabvier, and the common pink variety are the best and most vigorous growers. You should be able to grow some of the hardiest Tea Roses in open borders in Sussex, especially such varieties as Marie Van Houtte, Mme. Lambert, Perle des Jardins, Mme. Eugène Verdier, Countess of Folkestone, Grace Darling, Hon. Edith Cliford, Princess of Wales, Mme. Falcoot, President, The Bride, and Luciole. You are no doubt aware that some of the Hybrid Perpetuals bloom in early summer and again in the autumn, and amongst these are flowers of the brightest colours. Some other good ones are Mrs. J. Laing, Boule de Neige, Jules Margottin, John Hopper, Charles Lefebvre, Magna Charta, Duke of Edinburgh, Mme. Cambacères, Lord Bacon, Mme. Bertrand, La France, Crisman Bedder, and Ella Gordon.—J. C. C.

4237.—**Rose not thriving**.—I cannot tell you why it is that your plant of this Rose has not grown properly. The general fault is that it grows too much the first year and does not flower. Seeing that it is planted against a wall it is more than probable that the want of root moisture is the cause. In such a position the roots ought to have been well watered three times a week during the late dry weather. If that is not the cause you may safely conclude that the roots are weak, and only time and patience will restore them to an active state.—J. C. C.

— You must remember that during the whole of the spring of this year the weather was extraordinarily dry, and either very cold or extremely hot, and, therefore, on the whole, most prejudicial to growth, especially in the case of newly-planted shrubs, &c. Under such circumstances watering goes a long way; but at the best this is far inferior in effect to the natural moisture that falls from the clouds. Again, in my experience this is a Rose that does not always grow away at once, but requires time. Have patience. Keep the foliage clean and the roots moist; it will be all right in time.—B. C. R.

— It has often puzzled me why some plants of W. A. Richardson do not thrive. I failed with the first three which I put in, but now I have one growing vigorously. I put the first plants in during the autumn and the last in the spring, and it has struck me that possibly this Rose requires warmth to enable it to get well rooted and established, after which it grows freely and becomes vigorous. Perhaps I am wrong, but I offer the suggestion for what it is worth.—A. G. BUTLER.

4249.—**Treatment of Pot Roses**.—It is rather late to deal with, as they require cutting hard back, and although they may start into growth again I am afraid it will be too late to do much good this season. The better plan appears to me to be to cut them hard back at the end of November. Even then it will depend on the age of the plants whether they break into growth again satisfactorily or not. If the wood is four or five years old they will start irregularly, but the earlier they are pruned in the winter the more likely they are to break well afterwards.—J. C. C.

4237.—**Rose La France**.—I do not know that the situation influences the behaviour of this Rose. At any rate, not such a favourable one as yours is not at all likely to do so in the direction you mention. You must adopt some means of keeping the caterpillars away. Why not watch the growth of the Rose early in the spring, and when you see a curled-up leaf examine it, and remove the insect? You are not likely to lose your trouble by removing the Rose to another position.—J. C. C.

CALLAS.

There are few, if any, plants that are so generally useful for decoration as the Calla, which by a little management may be had in bloom for a very long season, as by forcing some and retarding others flowers may be easily produced at Christmas, and a succession continued till Easter and after. Beautiful as is the new one, *C. Elliottiana*, and valuable as it will be for general purposes, it will never be anything like so extensively cultivated as the old favourite. For many, however, *C. ethiopica* gets too large, but now that we have the miniature form of it in *C. Little Gem*, it can be substituted, and will be found, though corresponding with the other in all but size, to be about one quarter the height, with flowers in similar proportion. *C. Little Gem* grows and increases very freely, as small plants when pulled apart in the spring, or after having made their growth in the autumn, will be found to have numerous little tubers or plantlets about their base, all of which should be taken care of and potted, as in a year if grown on in the ordinary way they will flower. The plan I pursue is to plant them out in wide trenches, prepared after the manner of those for Celery, only not so deep, but quite as heavily manured. During summer they are mulched and kept well watered, when they begin to form fresh leaves and can take it up and have active roots. Early in autumn they are lifted carefully and potted. In doing this I give them light rich soil after slightly reducing the balls, and when the potting is finished I stand the plants in a deep pit or under a wall where they are out of reach of the sun, and keep them sprinkled overhead frequently during the day, so as to prevent flagging. Any that may be wanted in early are differently treated; as soon after they get established they are subjected to gentle heat by being kept in a warm-house. Forcing has to be slow, and the plants should have all the light possible, or they become drawn and weak in the leaf-stems. If Callas are not planted out the pots should be plunged in the ground or have loose litter around them to keep the roots cool and uniformly moist and be well fed with liquid-manure. It is also a good plan to top-dress with solid manure, using cow or sheep droppings, as plants will not flower freely unless they make strong crowns by the autumn. The flowers of Callas sometimes come with double and treble spathe, as in the illustration.

S. D.

FRUIT.

4241. — Strawberry growing for market.—I have not the least doubt that Strawberry growing for market can be made to pay in Somerset in a good season, but the one just past has been nearly a failure. With regard to sorts, James Veitch succeeds admirably in some places, and so do Sir Joseph Paxton, President, and Noble. You must give the plants plenty of room or the fruit will be small. James Veitch requires to be 30 inches apart each way, and the other sorts 2 feet. Fresh plantations of Noble should be made every year, when the plants may be set out 18 inches apart each way.—J. O. C.

4224. — Beet Gooseberries.—The large Gooseberries are much more planted now than they were formerly. The three best Gooseberries for cooking are Crown Bob, Industry, and Whitesmith. Perhaps the best Gooseberries for preserving are the Red Champagne and the Red Warrington, and the last-named is a very useful late dessert kind. The following are also good, but it should be understood that large Gooseberries require to be well ripened. The bushes require a good deal of thinning, and must be grown in any open, sunny position. Red: Companion, London, Wonderful, Roaring Lion, Clayton, and Bobby Yellow, Yellow Boy, Leveller, Glory, High Sheriff, Leader, and Brown Girl. Green: Ornate Green, Bumpor, Matchless, Keepeako, Lucy Brown, and British Oak. White: Antagonist, White Eagle, White Swan, Hero of the Nile, Freedom, and Overseer.—E. H.

4242.—Peaches in pots.—Yes, Peaches can be successfully grown in a cool greenhouse facing south; but you must understand that the pots must stand on the floor, and that the trees will require a good deal of room. The only

objection that can be raised against their being grown in pots is the possibility of the trees not getting water enough during the summer. If you are prepared to water them twice a day in hot weather I see no objection to your proposed plan. Pots 16 inches in diameter after the first year are the smallest sizes that should be used, and 3 inches more would be better. You had better begin with plants already established, and after getting them in the autumn shift them into larger pots. The best soil for them is turfy loam, which should be moderately dry when used, and be well rammed in about the roots. A quart of half-inch bones to each pot will be beneficial if mixed with the soil. Four good Peaches are *Ameden June*, *Early Grosse Mignonne*, *Dymond*, and *Sea Eagle*. Two good Nectarines will be found in *Lord Napier* and *Victoria*. Prune the trees into shape as soon as all the leaves have fallen, and keep the soil about the roots moist in winter as well as summer. The trees are not difficult to manage; at the same time, they want a good deal of attention from the time they come into flower until the fruit is gathered, as they are liable to be attacked with green-fly, and the leaves require to be syringed every evening.—J. C. C.

— There should be no difficulty in growing Peaches in pots in a cool greenhouse, providing the pots can be plunged in the earth inside the house during the summer months, which prevents the roots getting dry so quickly as they do when the pots are standing on an open stage. The trees must not be crowded by the regular occupants of the greenhouse, neither must the light be excluded from the trees by any overhanging climbing plants, like *Rosee*, *Tacsonia Van Volxemi*, or such like greenhouse plants. The month of November is the time to procure trees, those having been expressly prepared for this method of cultivating Peaches are the best and cheapest in the end. They are a free kind of pyramid in shape, with the branches closely pinched and pruned to four spurs. Pots 12 inches in diameter will be large enough for a

the shoots do not crowd each other. If the current year's shoots are more than 6 inches long, and well set with buds, they should be pruned back to that length. The trees will be all the better if left out-of-doors until the following February, protecting the pots from frost with long manure. Be careful to stand the pots on a hard base to prevent worms from making ingress to the soil, and interfering with the roots and drainage. When the trees are placed in the house the temperature should be kept low; not more than 45 degs. by night, with a rise of 5 degs. during the day. Syringe the trees about twelve o'clock daily with tepid water to induce them to break freely and maintain the roots in a moist state, but not too wet. When the new growth has reached 4 inches long pinch out the points to induce the base eyes to plump up and form fruit-buds. When the buds burst into bloom cease syringing and tap the branches daily to disperse the pollen and create a free "set" of fruit. When the fruit has fairly started swelling, syringe the trees twice daily with tepid water; the first time about eight a.m. and again at four o'clock, p.m. with a view to check the spread of any insect pest. Directly the fruit has passed the stoning stage supply the roots liberally with liquid-manure in a weak state, say every alternate time the trees require watering. Although Peaches enjoy abundance of air, it is not wise to expose them to direct draughts by opening both top and bottom ventilators at the same time when a cold east or northerly wind is blowing. As the fruit shows signs of ripening cease syringing the trees, and when it is all gathered, remove the trees outside, plunging the pots in the open where abundance of sun and air can penetrate amongst the branches.—S. P.

— Peaches can be successfully grown in pots. Anyone who doubts this should pay a visit to the Sawbridgworth Nurseries, where thousands of thriving trees may be seen fruiting in pots, some of very large size, and from twenty years to thirty years old, but still healthy and fertile.

If I were asked does pot-culture pay it would be difficult to answer that question without a number of ifs and buts, and going further into it than present space permits. To be successful the cultivator must take an interest in his work, as a good deal of attention is required during the growing season in watering, regulating growth, &c. Most of the good fruiting sorts may be grown in pots, but I should not recommend the shy setting kinds, such as *Alexander*, *Waterloo*, *Noblesse*, or *Walburton's Admirable*. All the Nectarines do well. Established trees may be purchased any time in autumn, winter, or spring. The earlier the better. If maiden trees are purchased for potting, have them home and potted as early in the autumn as possible. Prune rather hard the first season. Afterwards the chief pruning will be done in June. Do not stop the young shoots too soon, let them make at least 8 inches of growth before nipping out the central bud. The trees may be wintered outside, the pots plunged in litter, and the house filled with *Chrysanthema*. To my mind this is where the principal advantage of pot-culture comes in; the tree can rest outside and the house made useful. Take the trees back to the house in January and do what little pruning required, and wash the stems and branches with an insecticide. The re-potting when required should be done in autumn, as Peach-trees will be making roots all winter.—E. H.

4251.—Gathering and storing fruit.—Your enquiry as applied to the present season is an interesting one, as, if I am not much mistaken, we shall find that the time stated in the catalogues when Peaches should be ripe will not prove to be very reliable—indeed, if never is, for Peaches have so many vagaries with regard to ripening that no one can give more than an approximation of it, and this season it is likely to take a wider range than usual. Peaches and Apricots have already ripened in the open air a month in advance of the usual time. Windsor Peaches are nearly over, when, as a rule, they are not ripe before the middle of August. We may therefore expect a corresponding advance in all

Treble-spathed *Calla ethiopica*.

good-sized tree, which should produce three dozen full-sized fruits. Turfy loam, partly decayed, should form the staple of the compost. Old lime rubble is an ingredient which tends to keep the whole porous, an essential point where the soil is naturally heavy and retentive. A slight sprinkling of finely ground bones will be an improvement if added to the soil at the time of potting. If the pots are not too much crowded with roots, they need not be changed for the first year. A top-dressing will suffice. Any pruning required should be done at potting time. The main point to observe is to see that

URBANA-CHAMPAIGN

other fruit. Referring to your list of Pears, the Jargonelle is the only one that is sometimes eaten from the tree. Louise Bonne de Jersey should be kept under notice after the middle of September. The others you mention will probably be ready for gathering a fortnight later. You are right in supposing that it is desirable to gather the late sorts in batches, and, notwithstanding what I have said, allow them to hang on the trees as long as it is safe for them to do so, only bear in mind that there are indications that they will come from the tree freely earlier than in ordinary seasons. Keep all the late sorts in a fairly dark room, which is ventilated for two or three hours each day, and the temperature from 40 degs. to 45 degs. I see I have omitted the name of Williams' Bon Chrétien. This sort only keeps for a few days after it is ripe, which is about the middle of September. The only way to prevent the birds from pecking the fruit is to cover the trees with $\frac{1}{2}$ -inch netting.—J. C. C.

4248.—**Fruit-trees for garden walls.**—Although Apple-trees grow well against walls, it seems a pity to take wall space with this fruit when such fine crops can be gathered from trees growing in the open. Walls are generally reserved for such fruit-trees as are not a success when planted in the open. For instance, the choice kinds of Pears, Cherries, Apricots, and Peaches, in addition to Plums. I will give the names of some of the best varieties of the fruit mentioned, "Mr. Piercy" can then use his own discretion as to how he will proceed in the planting of them. Plums are best grown as fan-shaped trees. No less a space than 12 feet should be given for this class of trees. As to varieties, Green Gage, Kirke's, and Jefferson are good for dessert, Victoria and Orleans for kitchen use. All are excellent cropping kinds. As to site, an eastern aspect answers well for Plums. Cherries need the same space as the former fruit, a wall with a western exposure suits this crop. Morello grows admirably against a north wall; Governor Wood, Bigarreau Napoleon, Elton, and May Duke are good free-bearing dessert kinds. Pears succeed as cordons, planted 18 inches or 2 feet apart. Under this system so many more varieties can be included. If this is not an object, horizontally-trained trees answer well and give heavy crops of fruit. Jargonelle, Louise Bonne de Jersey, Marie Louise, Pittmaston Duchess, Williams' Bon Chrétien, Glou Moresau, and Winter Nelis are good sorts to grow in every respect. Of Peaches, Alexander is much the earliest of any. Gros Mignonne and Bellegarde are good successful kinds; in fan shape is the way they are invariably trained. Moorpark is by far the most reliable Apricot. With regard to Apples, both kitchen and dessert, trees grown as bushes are much to be preferred. These should be grafted on the seedling Apple or Paradise-stock, as they commence bearing the second season following planting; indeed, many would bear, and do so sometimes, the first year, but it is not wise to allow them to do so, as the growth of the tree is weakened by the extra strain placed upon it in its weakened state through interference with the roots in planting. The following is a good selection of sorts: Kitchen: Lord Grosvenor, Warner's King, Echlinville, Lano's Prince Albert, Golden Spire, Bramley's Seedling, and Newton Wonder, the last two being late keeping varieties. Dessert: Devonshire Quarrendon, Red Atrachan, Lady Sudeley, Irish Peach, Worcester Pearmain, Cox's Orange Pippin, King of Pippins, Blenheim Orange, and Sturmer Pippin. In all cases I do not advise that cheap trees be bought; they are very often the dearest in the end. Procure those well rooted, and not more than four years old. The first week in November is the best time to plant fruit-trees of all kinds. A mchling of half-decayed stable-manne, laid on the surface-soil 2 inches thick will preserve the roots from frost, and act as a conservator of moisture to the soil during the summer if the weather is at any time of a protracted drooghty character. Previous to planting the trees the soil for 2 feet deep should be well broken up, not only to enable the roots to run freely into it, but as a means of drawing off the surplus water after heavy rains, which chills the soil near the surface.—S. P.

2939.—**Treatment of a Hydrangea.**—If the young growths of this season are well ripened flowers will form on the ends of the

shoots next spring. If the plant is set out in the garden it should be lifted and put in a pot in September, unless the position is very warm and sheltered. They flower outside on the south coast, but north of London it is rare to see it flowering outside.—E. H.

HOUSE & WINDOW GARDENING.

4227.—**Plants in a bedroom.**—Strong-scented plants are not suitable for a bedroom. In the early spring months, Snowdrops, Blue Scillas (Squill) and Tulips, and Lily of the Valley would be suitable, but not Hyacinths. Plants which require much water, such as Spiraeas should, I think, be avoided, but a nice White Azalea would last a long time with careful watering. Primulas and Cyclamens also, and later on Gloxinias, would be easily managed. Then in summer there are "Geraniums," Fuchsias, and Tuberous Begonias. At the present time Campanula isophylla and its white variety are charming table ornaments, or on brackets near the window. In the autumn Saarberough Lilies, with a Pompon Chrysanthemum or two, with a Palm or a Fern or two, will be very attractive. The best Palms for rooms are the Kentias. They are graceful in habit, are not difficult to manage if watered carefully and the foliage kept clean, and they do not require large pots so soon as the Latonias and Scaforthias.—E. H.

—We do not think it is advisable to have many plants in a bedroom, but plants that thrive in rooms generally will also succeed in a bedroom, if given a fair share of light, air, and carefully watered. You would have in the window the pretty Campanula murelis (a mass of bloom) in the summer, *O. carpatice*, *C. isophylla*, and the variety *alba*, besides, of course, Pelargoniums, but they will need to be replenished, as all flowering plants. Things in bloom do not keep very long under such conditions. The *Aspidistra* (green and variegated forms), *Aralia Sieboldii*, such good hardy Palms as *Corypha australis*, and *Enlalia japonica*, will thrive—the latter to have plenty of water. Always keep the leaves carefully sponged with tepid water to remove accumulations of dust, and stand them out in gentle rain occasionally. This refreshes them greatly.—O. T.

4198.—**Plants for windows.**—It may be feared that the Roses, hardy though they may be, will not do much after the first year if the "tawn" be London, as Roses will not stand a smoky atmosphere, even under the best cultivation. For the north windows either Ferns or foliage plants must be selected, as flowering plants would not do well there. The best room Ferns are those of the *Pteris* family—*Pteris serrulata* and *Pteris cretica* being easily procured, and standing well in a room. There is a pretty variety of the first, *P. serrulata cristatum*, with crested tips, which is especially handsome as a room plant. English Ferns, too (Crested Hart's-tongue—*Scolopendrium vulgare cristatum*—being the best as evergreen), are well worth growing now that they have been so much improved by special cultivation, and these give no anxiety in the coldest weather, being quite hardy, of course. Palms, too, would grow in the north windows, and these are capital room plants, for they do not need potting often, and do not care for sunshine. They must, however, have their broad leaves kept thoroughly clean by sponging off the dust occasionally, and should never be allowed to become dust dry, although water should not be given to them until the surface-soil is dry, when enough to run through the pot (soft water, with the chill off in winter, in preference) should be given them, their canner being emptied half an hour afterwards. *Phoenix dactylifera* (the Date Palm), *Corypha australis* (the Cabbage Palm), *Scaforthia elegans* (the Bungalow Palm), *Chamaerops elata* (the Fan Palm), and *Chamaerops humilis* (the Dwarf Fan Palm) are amongst the best Palms for a room, for they will even stand a little gas occasionally if the leaves are kept sponged, although gas usually kills plants, and no flowering plant will stand it. *Aspidistra lurida*, too (called the Parlor Palm, though not really of the Palm family), is a first-rate gas-resisting plant, which only needs the same conditions as the Palms; and *Ficus elastica* (the India-rubber-plant) may be placed in the same

category, its broad, shining leaves being very handsome. One or two of the *Dracaenas*, *D. indivisa* and *D. congesta*, stand well in a north window, and *Grevillea robusta* (the Australian Silken Gask) is a beautiful Fern-like little tree well worth attention, as it does well in a room for a long time. For a west window flowering plants may be tried, though the aspect is not so good as that which gives the morning sunshine. Fuchsias, Zonal Polargoniums ("Geraniums"), Perpetual-flowering Begonias, and a host of other plants would do here for a time, but it would not be possible to give the special cultivation of each in the answer. "Joseph Martin" will find an article on these Begonias in the last issue of GARDENING, and every week there are some particulars of the cultivation of room plants, giving the details necessary. Bulbs of many kinds may be put in during the autumn, and these will flower in early spring, but if "Joseph Martin" will dole which he wishes to grow, and give more particulars as to whether any garden, frame, or yard is available for plants not in flower, the special cultivation of each kind of bulb or flowering plant will be given with pleasure. There is yet another large group of plants which might be made available for these windows—i.e., hardy plants, which can be grown in pots out-of-doors until they begin to bloom, and then lifted into the window. In this way Carnations, Gladioli, Lilies, Pentstemons, Foxgloves, Wallflowers, and many other blossoms may be had at a slight expense, and without much difficulty, the pots being sunk to the rim in a bed of fine ashes, in a back yard or garden, or placed in boxes of ashes on the leads. Good soil, regular watering, and slight protection during winter, when these plants should have 2 inches of ashes placed round their stems, and a bit of carpet over them during very severe weather, will keep up a good supply of hardy plants in this way.—I. L. K.

4193.—**Roses in a window.**—The Roses in question are not so delicate as the Tea-scented varieties, and will not need much protection during the winter. The more they can be out-of-doors the better for them, as Roses do not do well for long together in a room, soon becoming too weak to flower. When they have done blooming they should be placed in the open air, the pots sunk in a bed of ashes to the rim, or else, if no garden be available, a box of ashes will do as well in a sunny yard or outside a window, or on the leads. Here they can remain till October, when they should be pruned a little and repotted, giving them a shift into the next sized pot, with good light compost (turfy loam, leaf-mould, and a sprinkling of soft and sand, but no new manure) and excellent drainage. As amateurs do not always understand how to repot, a few words of explanation may be useful. Cover the hole with a piece of broken pot (the concave side being downwards), and place round this smaller pieces of crook, so arranged as to allow of escape of water through the interstices. Cover the crooks with a bit of Moss (which lasts a long time without rotting, and keeps the soil from clogging the drainage), and sprinkle this with a teaspoonful of soot, which is a strong manure, and not only helps to nourish the plant, but keeps out worms and insects. Then place a little soil over this, and turn the plant out of the pot into the left hand. Remove the drainage, and spread out the lower roots slightly, also pare away the upper soil, so far as it does not interfere with the roots. Then place the ball of the roots in the new pot (which must be thoroughly clean and dry inside and out to start with), and pack the fresh compost firmly round it, using a blunt potting-stick to prevent any empty spaces between the pot and the ball of roots. Finish off tidily at the top, leaving at least an inch for a thorough supply of water, and in most cases more than this, so that a top-dressing can be applied. In pruning the Roses cut out first the weak twiggy wood, which is often half dead; then shorten the stout new shoots to a good dormant eye, about 4 inches from the surface-soil, or more if quantity and not quality of bloom is desired, the piece thus cut off (of this year's growth) can be put into the open ground as cuttings, placing them in firmly, with one eye only above ground, in sandy soil. The Roses will do best out-of-doors, the pots being protected with ashes, until severe weather sets in, when they may be placed in the window of a room without a fire, as close as possible to the

glass, and will begin to bloom early in the spring if given regular watering when necessary, with an abundance of air. In mild weather they should stand outside as much as possible. Rain will help to cleanse the foliage, but a bit of soft old sponge and soapy water should be always at hand to destroy the first symptoms of green-fly, their special enemy.—I. L. R.

FERNS.

THE BRITISH POLYPODIES.

A "LADY READER" has been collecting some of these in Yorkshire and Cumberland; and now wants to know what she is to do with the roots to get them to grow? Now, according to my belief, there is but one species of *Polypodium* native of Britain, and the Beech Fern and the Oak Fern I do not recognise as true *Polypodiums* at all, but these belong to the genus *Phegopteris*, which by some is made a sectional name only. There, however, appears to be good reasons for these authors who give it generic distinction, with which I quite concur; but in the present case I will just say a few words on the British *Polypodies* and include these, for argument's sake. The Oak Fern (*P. Dryopteris*) is one of the most charming of our native Ferns, its beautiful bright-green fronds rendering it conspicuous and noteworthy to all beholders, and its young fronds are peculiar in having the ternate divisions rolled up like little balls upon wires. This Fern is widely distributed all over Europe, beside other places, and, amongst other places in Europe, England appears to be one over which it is widely distributed, for I have gathered its bright light-green fronds when walking about in the Derbyshire Peak country, all about in Yorkshire and Lancashire, where it grows in great abundance in the stone walls which divide the fields, and which appear well suited for the requirements of its creeping rhizomes, so much so that I was tempted to build a similar one in my rockery to establish this species, and which I plan to recommend to the attention of my enquiring friend, and she will find that, although these plants, will not make much visible progress this season, their fronds will peep out early in April of next year. I have found this plant in so many places in going North and in Wales that I cannot name them, but I have never found it in Ireland, but I believe that it is to be found in that country, but that it is very rare. The Limestone *Polypody* (*P. Robertianum*) is another deciduous species of quite a different shade of green. It is larger, too, in its fronds, which have a coating of slender, fine hairs. Altogether, I am of opinion that this plant should rank as a species. I do not agree with those who make it rank as a sub-species. It is a Fern that appears to delight in the sunshine, and it only grows in calcareous soil. This Fern would seem to be spread through many counties, appearing plentiful in the North of England, but I have never heard of its being found either in Scotland or Ireland.

THE BEECH FERN (*P. vulgaris*) is a well marked and very distinct kind. When growing strongly the fronds attain to a foot in height, the lowest pair of pinnae being deflexed, whilst the others incline upwards, and the whole frond has a pubescent appearance. It seems to be fairly distributed through the three kingdoms. All these plants appear to be pretty constant. Some few differences I have observed, but when the fronds die down the variety dies out, and one seldom sees it again, and they will all grow together, so I advise my enquirer to plant them in what in Yorkshire they call a toad-holing wall, when, as I have before remarked, they will make good progress, and be able to show their beauties to the eye next spring. The alpine *Polypody* (*P. alpestre*) and its very delicate variety *P. alpestre flexilis* have a general resemblance to the Lady Fern. Some authors, indeed, class it with that species, but I think in this they are much to blame for so doing. It is a plant of much interest, as it is within about fifty years being discovered to be new, and it was until then looked upon as belonging to the Lady Ferns, with which it grows in Scotland. This plant and its varieties grows well in well drained loam and peat, and it likes a shady situation; and now we come to the common *Polypody* (*Polypodium vulgare*). This is a [throughout] at least, when it can get moisture to its roots—but

I have some roots which lost their old leaves through drought, and which have also been subjected to the very dry season we have had, and these did not show any sign of growing until the month of July, when they began to push up fresh fronds. It is a plant widely distributed throughout the temperate regions of the Globe. The fronds of the typical plant are dull-green in colour, which is relieved on the under side by the orange-coloured apices. Of this plant there are many varieties, and amongst them all, perhaps the most beautiful is *trichomanoides*, which has finely divided fronds of a most exquisite character. The Welsh *Polypody* (*P. cambrium*) is another grand form, which has the pinnae again divided which overlap. This form has never been found in a fertile state. *Cristatum* is another form of which there are several varieties all bearing the same name. But amongst the other named varieties I would particularly call attention to the forms called *grandiceps*, and the beautiful plant called *omnilaceum*. There are many others, and doubtless there remain many good forms, especially in the Ardennes Mountains, where this species abounds. To grow this plant well

Oak Fern (*Polypodium Dryopteris*).

it should have a good depth of leaf-mould beneath it, and this should be kept always wet, and its rhizomes should not be buried. J. J.

4233.—Weeds on a lawn.—There is no more satisfactory way of getting rid of big weeds on lawns than to dig them out, and no better time could be had for doing so than the present, as the Grass is growing rapidly and will soon cover over the vacant spaces. With regard to the Yellow Hawkweed, of which you complain of having so much, I hardly know what to recommend you to do. I know, in one sense, it is a tiresome subject, as the flowers remain closed until the sun comes out, and then they burst into a sheet of yellow, which is objectionable; on the other hand, it is a case of the survival of the fittest, as it grows where Grass does not thrive in dry weather, so that if you get rid of the weed it is possible that your lawn may be bare of Grass in a dry summer. For that reason I have had to let this weed remain, and when it has not been necessary to use the lawnmower I have waited until the flowers were out, and then sent a man with a sharp scythe and cut them off, as it is almost impos-

sible to toll where the little flower-heads are until they are expanded. This weed only grows in quantities where the soil is thin and poor.—J. C. C.

—You cannot do better than set upon the advice often given, and that is to root them out with an old knife, or cutting off the plant close to the ground. This is the best and old plan. Bare spots may be made good by pieces of turf, so as not to make unsightly patches.—C. T.

4203.—Destroying ants.—The best thing you can do is to dig down by the wall and try and find where the nest really is; you might then be able to reach it with boiling water or diluted carbolic acid. If the nest is in the foundations you might osment the part over. Are the ants doing any harm?—G. S. S.

4213.—Extirpating Horse-radish.—You cannot do better than continue the course you are adopting. Got up as many of the old roots as you can. Your efforts will be crowned with success at last in spite of this opinion of your gardener. Ever cutting off the leaves persistently will kill the roots.—G. S. S.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editors of *GARDENING*, 37, Southampton Street, Covent Garden, London. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by adding, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4209.—An old Apple-tree.—What should I do with so old an Apple-tree that does not bear well?—HUGH DESPRAE.

4270.—Basket-plants.—What hanging or basket-plants can I have in winter for a greenhouse which has no means of heating?—A. J. GIBB.

4271.—Manure for Vines.—Will someone please to let me know if glass is a good manure for Vines in a boiler under glass?—B. D. FERRIS.

4272.—Roses for an outdoor border.—Will someone please give me a list of Roses with best foliage for out-of-doors border?—B. D. FERRIS.

4273.—Sorel and French Beans for winter.—Will anyone kindly tell me how to preserve Sorel for winter use? Also French Beans?—S. LINDEAY.

4274.—Breaking stones.—I want to break up some stones, flints, &c., very small to mix with my garden mould. What is a cheap and easy way to do so?—M. M. OWEN.

4275.—Treatment of Cactuses.—What soil do Cactuses require, and how are they propagated? I have one or two White Cactuses. Are they rare?—HUGH DESPRAE.

4276.—Everlasting Peas.—How are Everlasting Peas propagated? By seeds or by cuttings? I have a White Everlasting Pea; I am told it is rare; is that so?—HUGH DESPRAE.

4277.—Winter flowers.—Will anyone kindly give the names of some flowers which will blossom in winter in a moderately warm greenhouse? Locality, Ramsgate.—G. WILLIAMS.

4278.—Begonias in pots.—I have a considerable quantity of Begonias in pots, and will be glad if someone will tell me how to keep them through the winter, as I lost a lot last year?—F. T.

4279.—Single Begonias as cut flowers.—I am anxious to exhibit some single Begonia blooms, but find when cut they soon wither. Will anyone kindly give me a remedy for this?—F. G. I.

4280.—Fig-trees under glass.—I have some Fig-trees under glass. They do not bear well. Will anyone kindly tell me how to treat them? Do they require much manure and water?—JANA SPASAROW.

4281.—Freesias in a cold house.—Can I grow Freesias in a house without heat? If so, how? I have never flowered this season, but made a great quantity of small corns. Locality, Aldershot.—H.

4282.—Destroying wireworms.—I have about 20 peels of newly broken-up ground, and it is infested with wireworms. What is the best thing to use to destroy them? Locality, High Barrow.—W. WILLIAMS.

4283.—Roses on a low wall.—I have a low brick wall, facing north by east. Will Tea Roses do on it? I have been told they will. If so, will someone please to recommend the best sorts?—LAWRENCE EVANS.

4284.—Carnations, &c.—I am puzzled to know the difference between *Cornations*, *Pleocles*, and *Pinks*, also the faded *blazes* and *selfs*. Perhaps someone will kindly help to enlighten me on these points?—C. R.

4285.—Fuchsias in a cold house.—I lost my *Fuchsias* under the roof of my cold-house last winter, and have not flowered about 4 feet high. How can I keep them alive so as to grow on again next spring without cutting down? Locality, Aldershot.—H. A.

SELF-COLOURED FLOWERS.

The boldest effects we have in our gardens are produced by self-coloured flowers, and it is a pleasing sign of the times that these are in general request. In vari-coloured flowers one must make a broad distinction between those whose tints are harmoniously blended and those of an opposite character. Some of our garden flowers are naturally harmonious in their varied forms, such as the *Alstromeria* and the *Tea Rose*; but, on the other hand, the zeal of the florists in improving other flowers has been carried to excess, and we have crude mixtures of colour that are not pleasing to the eye nor productive of the best results. Those who during the last few years have urged the claims of

CARNATIONS, and advised their extensive cultivation in gardens, have pointed out the necessity of mainly growing the kinds that possessed a clear self colour. There are a general similarity and monotony of tone and tint about the flaked and bizarre forms of the florist, and some of them present combinations of colour that are harsh and offensive. Even in self colours there is variety of tint sufficient for any purpose, and when we deal with flowers of this kind we may arrange them to produce results much more pleasing and simple than are ever obtained from the violent contrasts that abound in a great deal of present-day flower gardening. Antirrhinums are capable of producing a lovely effect if grouped in self colours. This is quite true, and not of Antirrhinums alone, but of many pretty garden flowers. We have got so accustomed to the very much mixed strains now in commerce that we think of nothing further and content ourselves with them. Now, Antirrhinums are very useful garden flowers, so persistently do they bloom if relieved of the burden of ripening seed. Several years ago I saw a group flowering in a garden, and of all the plants one only impressed me with its beauty; it was a rich crimson self. Later on the plant was sent to me, and I struck all I could from it. The following year a group was made in the garden, and the effect was so lasting and brilliant that I was at once convinced the right thing to do was to have a few good selfs. I raised a batch from seed, and was fortunate in obtaining a creamy-white and a creamy-yellow kind, also a very rich dark velvet-crimson, which is very beautiful upon close inspection, but does not produce a brilliant effect equal to that of the first kind. All four, however, have been grown in groups this season, and they have been a mass of bloom since Jane till recently, when all the first spikes were cut away, and from now on into the autumn the plants will keep blooming from smaller lateral spikes. There is no necessity to name them, for, as "A. D." says, six decided self-coloured kinds would be ample for any place. It is a simple and easy matter to strike a batch of each from cuttings in autumn and keep the plants under cover for the winter. They can be put out quite early in the spring and are in

flower by the time that tenderer, but not more showy nor more profuse blooming plants are safe outside.

PENTSTEMONS of the present day are very disappointing, and if there are any good bright selfs in existence they are very scarce. I have a kind that I use largely with summer bedding plants. I found it on the place, and it blooms from June to November. A batch of cuttings is put in in a cold frame during October, protection is given when frost is very severe, and the plants are planted out in April. Nothing in this way and for this particular purpose could give a better return for so small an outlay. Up to the present my endeavours to obtain kinds as good in different hues have not been rewarded. A large lot of seedlings is now blooming, but from my point of view they are worthless. Many are positively ugly, and dingy in hue, and those that have pretensions towards pretiness are not selfs. There is not enough body of colour. The type that predominates is characterised by a narrow belt or band of colour running round the edges of the petals, but the tube of the flower is of an entirely different hue. It would serve the interests and meet the desires of many if those who make a speciality of this flower would endeavour to produce and supply good selfs. Last season I saw a lot of new kinds at the Drill Hall. The spikes were fine, the flowers large, but the colours all partook of the orthodox type, and not one of the kinds commended itself to me for bold use in the flower garden. But whilst we deplore the want of good self-coloured, kinds of particular families of garden flowers it is most in justice to say that recent years have witnessed a great improvement among many things in the direction desired, and we may reasonably assume that the good work will be pursued. Before dismissing this first part of the subject, however,

SWEET WILLIAMS might be mentioned as flowers that would be ten times more popular if the many shades that characterise the flower could be had in pure fine self forms. A rich crimson, pure white, or delicate pink without the inevitable lacing or staring eye would be valuable. Stocks afford the best example of what can be done in a few years. They are all, or nearly all, selfs, and embrace the richest and deepest, or lightest and palest hues. H.

A note on *Tropaeolums*.—One usually finds that the *Tropaeolum* is not grown in many places for the reason that the plants run to leaf. This is scarcely the case, as they do not run to leaf, this feature being characteristic of the variety. I lately noticed, however, two kinds that produce few leaves and bear their flowers above them, so that they are well seen. This is the type of *Tropaeolum* so desirable. *Vesovius* is the name of one. It has dark-coloured foliage, quite of a bluish-green, and brilliant scarlet flowers, which are in rich association. This kind will assuredly get popular. It is better, so far as I can see, than *Empress of India*. Then I must give a good word for another variety of similar habit, named *Clibran's Yellow*. The leaves are of an ordinary green colour, and the flowers

bright yellow—not, however, a staring shade—and literally hide the foliage. Both, I believe, are new and therefore not yet well known.—C. T.

BEDDING "GERANIUMS."

THESE have made but very little growth this season, and the chances of getting anything like a full supply of cuttings are remote—at least, until too late in the year to be of much use, for if dull, wet weather should prevail, the growth made during the latter part of summer will be of the softest nature, and not likely to make good plants without a large percentage of losses. Under present aspects the best course to follow will be to start the work of propagation at once, getting off all the cuttings that can be spared as soon as possible, and inserting them either singly in thumb-pots or five in a 3-inch pot. At this early period they will strike well in any position, but to shelter them from heavy rains I like to have them in cold frames, where the lights can be drawn off in fine weather, and replaced if heavy thunderstorms occur; just enough water to keep the shoots from shrivelling is all they require until they have made roots, when they may have a little more liberal supply. Later batches of cuttings will need more care, or the losses from damping will be great. Any plants that have been kept in small pots through the summer should be headed down, and the tops used as cuttings, and the stumps, if kept rather dry, will break out into growth, and make very nice dwarf bushy plants for next season. Old plants, if lifted before they get frost-bitten and have most of the old leaves picked off, may then be stored thickly in pots or boxes, and placed in gentle heat for a little while to get rooted, give an excellent supply of cuttings very early in the spring, which, under careful management, will make good plants by May.

J. G., *Hants.*

4274.—**Breaking stones.**—Except in very small quantities you will find this a difficult and expensive job without the aid of machinery. With a "devil" disintegrator and a steam-engine you may grind up stones of any kind by the ton; but short of this it will be far cheaper and better to buy or obtain a load or two of pit, river, or sea-sand, road-grit, or the like. Finely-sifted coal-ashes would answer the same purpose, and afford some amount of actual outfitment as well; or if your soil is heavy, some of it might be burnt in heaps with small coal, and the products mixed with the soil will greatly aid in rendering it lighter and richer as well.—B. C. R.

4291.—**Calcined bones and leather.**—All animal matter is useful as a fertilizer, and I have found the above a very good manure upon etiff ground, and also for pot Roses. Some years ago a friend of mine was so unfortunate as to have a valuable stock of leather and bones burnt. I used some of the ashes, and found them one of the best and most lasting fertilizers, but it would, of course, not pay to burn them for this purpose. "Coastal Residue" may also be used in any connection with plant life.—P. U.

Top-dressings of rich compost are still valuable, though the roots are less active on the surface than they were a couple of months ago. Woodlice have always been all this year a source of trouble, but by care in the selection of soil and manure, and thoroughly cleaning the house when the crop is changed, I have no trouble with woodlice this season, and hope the same care will in future keep us entirely free from this troublesome pest. One of our greatest troubles as regards insects have been the earwigs on the *Chrysanthemums*. Black and green-fly we can deal with effectively, but the earwigs in some seasons are a terrible worry. I have placed traps everywhere, and this has resulted in some benefit, but the greatest benefit has been obtained from looking over the plants at night when the insects are feeding and picking them off the plants, giving them a pinch, and casting them down.

FERNS.

ARRANGEMENT OF FERNS.

FERNS not only must be grown well, but also arranged artistically, as shown in the accompanying illustration. Owing to the variety that exists amongst them, they afford a vast field for effective grouping. Although most Ferns are individually graceful in growth, yet the aspect of a fernery is greatly beautified when the plants are arranged with taste. Amongst the many different ways of arranging Ferns so as to produce a satisfactory result, and at the same time show each plant off to the best advantage, there are two which may be especially mentioned. The first relates to ferneries in

growth, such as *Blechnums*, *Lomarias*, &c., but all should be so arranged as to make a pleasing group. It may also be stated in favour of this last mode of growing Ferns that it is the more useful, as it allows the same plants to be used in different ways for decoration in rooms, and for mixing with flowering plants in the conservatory, &c. In all cases avoid symmetry in grouping Ferns. They certainly do not gain anything by being set in a formal manner, and overcrowding is also another evil. If placed too close together individuality is lost, and wherever there is convenience they should stand either on a solid bed of earth or on a layer of ashes, kept constantly moist. Very few insects will make their appearance then, and this way of placing them will be found much superior to that of setting them on wooden staging, where the air between the plants is constantly in motion, and insufficiently moist. A. R.

MAIDEN-HAIR FERNS.

No matter how many substitutes for Maiden-hair Ferns are introduced, the old *Adiantum cuneatum* still retains the lead, and is ever increasing in popularity. But, unfortunately, many amateurs fail to grow it well, and certainly as a room plant it is but short-lived, if compared by the endurance of Ribbon Ferns.

Indoor fernery artistically arranged.

which all specimens, large or small, are planted out without reference to regularity or symmetry—allowing them, in fact, to grow comparatively wild, so as to imitate as much as possible natural growth. Under such conditions, plants with broad and bold foliage intermix with others of a different character, and form masses of vegetation, remarkable for picturesque beauty. A fernery of this kind is not, however, within the reach of everyone. Many cannot afford space for grouping of this kind, and, on the contrary, they have to content themselves with a few specimens in pots, and with arranging them at intervals, so as to form various combinations. In all arrangements of this kind striking contrasts should be always kept in view, which can be readily effected by selecting species of quite different habits, and grouping them not only according to size and form, but also colour. Even a few plants judiciously put together in a comparatively small space may be made to look well, provided the best mode of grouping is adopted, spreading species being so disposed as not to interfere with the growth of such as are more upright. For example, broad-foliated kinds, such as most of the *Polypods*, *Davallias*, &c., should not be brought into too close contact with kinds having more finely divided fronds, such as *Lastræas*, *Pteris*, or *Davallias*, of the finely-out section, nor with plants of upright

I lately saw a beautiful lot of specimen and also smaller plants, grown by an amateur, that would have done credit to any exhibition tent, yet the owner did not pretend to have any special knowledge of their culture. The following appeared to be as nearly as I could gather the routine of culture pursued: Repotting was done as soon as the plants were seen to be pushing up young fronds vigorously from the base, and, contrary to what market growers aim at, which is a large plant as they can get in the smallest pot, the owner gives liberal shifts, and grows his plants on from small 3 inch pots right up to the largest pots he can get. The soil employed is turfy loam, broken up fine, a little peat and leaf-mould, and sharp sand. This is rammed into the pots quite firmly, and the plants only receive a moderate supply of water until the roots have taken full possession of the new soil, when during the hottest months of the year they receive copious supplies of rain-water, and the growth is pushed on rapidly by means of weak liquid-manure, of which the main elements are soot and cow-manure. Under this treatment they push up a perfect forest of tall fronds, which spread out in all directions, and soon become of a deep-green colour, and as the days get shorter, less liquid manure is given, and the plants poured to plenty of air. They will last for months in good condition. J. Groom, Gosport.

ORCHIDS.

CATTLEYA AUREA.

C. AUREA is said to come from the State of Antioquia, in Colombia, and as various other plants from the same district appear to enjoy a medium temperature, then this Orchid, I think, should be subjected to the same treatment. After the flowers have faded, therefore, and as soon as the growths are fully made up, the plant should be removed to cooler quarters. I would not put it into such a low temperature as that of the ordinary *Odontoglossum*-house, but rather into a house a few degrees warmer—such a one in which the *O. grande* is reared in would suit it admirably, and in which the atmosphere is dry, the object being to prevent plants starting into fresh growth before the spring. At that season the plants should be removed to the growing-house, and after being re-surfaced with good peat-fibre and a little chopped Sphagnum Moss, they may be watered moderately, and the air kept moist, so that the growths then will soon begin to make a move. Here they should be encouraged to grow vigorously, and this growth should be surmounted by a flower-sheath. Too many people there are who neglect their plants, and do not remove them to a drier atmosphere soon enough, and the consequence is that the young eyes begin to push up in the autumn. Now these growths made in the winter can never "come away" with the requisite strength to produce a flower-sheath, and if this time of starting the growths is once adopted it is a very difficult thing to get them right again, and the consequence is one never gets any flowers. One may, however, err rather in removing them too soon, but do not let the growths start, at any rate, before the turn of the New Year, and if they can be retarded for a month or two later so much the better. In the case of plants that have been neglected and allowed to start into fresh growth in the autumn, they should be kept warm and encouraged to grow vigorously and quickly, so that the bulb may be finished before spring, so that after a short rest the plant may be set to work again to make another in the summer months, which may flower. At any rate, the plant after the next autumn could be reared comfortably through the following winter. I look upon the enforcing, as it were, of a right season of growth as being the great secret in obtaining flowers, and this variety, *C. aurea*, I consider to be freer blooming than the typical *C. Dowlena*. MATT. BRAMBLE.

LÆLIA PUMILA.

This plant is said to be a native of Mont Santa Catherine, where it is said to grow upon the stems and branches of trees on the mountain sides, up to 2,500 feet elevation. In this position the plant gets an abundance of air and a fair amount of warmth. I have always found it to grow well in the Cattleya-house, and I like to use for it best some small earthenware pans or pots—which should be hung up near the roof glass—potting in some little peat-fibre and Sphagnum Moss, not using too much, as it does not like a great amount of soil about its roots. Some thirty years ago it was thought difficult to manage, too much material being used about its roots. At that time, then, a greater amount of heat was maintained in the Cattleya-house than is found to be necessary now, and far less air was given. During the summer season this plant should be kept fairly moist about its roots, and a liberal quantity of moisture should be maintained in the air, and during the winter just sufficient water should be used to keep it moist. I have found this to suit its requirements far better than keeping it dry, and in the winter season it should be kept at the cool end of the Cattleya-house. I say the cool end of the house, because in some houses a great deal of difference exists in the warmth of the part nearest to the boiler and the part farthest removed from it. M. B.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of plants, flowers and good fruits and vegetables for drawings. The drawings so made will be engraved in the best manner, and will appear in due course in GARDENING ILLUSTRATED.

THE KITCHEN GARDEN.

THE TRUE AUVERGNE PEA.

This is a French Pea, and is a good secondary variety. It crops freely, and is especially good in dry weather. Thus it is of value in such a year as the present, when Peas have suffered severely from the dry character of the season. The pods, as shown by the illustration, are of curved form, and well filled with Peas. It is quite distinct from the Auvergne Pea of many English lists.

SOWING CAULIFLOWERS IN AUTUMN.

Most cultivators are aware that Cauliflowers can be sown in spring and got in quite as early as that which has been sown in autumn. Spring sowing may answer very well where pits and frame accommodation are unlimited. But this is not the case in many gardens. I will remember seeing at The Deepden, near Dorking, when Mr. Burnett had charge of these gardens, early in May a fine lot of spring-sown Cauliflower. This was grown in some sunk wooden frames. The plants were put in much the same way as when planted out in the open ground. At that date they were well advanced, and no doubt would be ready to cut as early as my autumn-sown. After trying to obtain Cauliflowers as early as possible in several different gardens and localities, growing them in diverse ways, I have come to the conclusion that no way is so reliable as growing them in hand-lights for the first supply. During the last four years I have made a point of growing these in three different ways, namely, in hand-lights, potting up a batch of plants and growing on a third lot in boxes. These two last lots are grown in cold frames during the winter. Every year I have cut those from the hand-lights from ten days to a fortnight earlier than from those grown in pots, although these latter were well attended to, planted out of 3-inch pots, one plant in each, and well sheltered with Fir branches for a time after. Both batches—namely, those grown in hand-lights and those from pots—were grown side by side on a south border. For the last three years I have cut the first Cauliflowers from the hand-lights the first few days in June. One season I was not without Broccoli or Cauliflowers the whole year round, and this without growing them either in pots or frames, duly protecting the Broccoli in winter by placing them in frames. I have tried sowing early in January on a hot-bed, afterwards pricking out the plants into cold pits or boxes, and then removing to the open border. I now rely on autumn-sown plants to keep up the supply till I can get those in from seed sown in cold pits or under hand-lights in March. I plant a part of those that I winter in boxes in the open garden and a portion on a north border. By so doing a succession is kept up with but little trouble. Some cultivators recommend a certain time for sowing. This should be done according to locality and situation. From the second week in August to the end of the first week in September is a good time. I rely on such kinds as Extra Early Forcing, Weischen, Early London, and Autumn Giant. I.

KITCHEN GARDEN NOTES.

The present is a very busy season in kitchen gardens, for what may be termed the second seed-time is now upon us, and every day is of the utmost value—in fact, a day now, in the matter of growth, is equal to three later on in the season, and owing to the peculiar nature of the summer, the first sown crops of many kinds of vegetables are of little value, and secondary, or late sowing or planting, is all the more important to fill the gap. The following crops need early attention, viz—

CAULIFLOWERS, for the latest crop, should be put out at once; they succeed best on firm soil; the Early London and Autumn Giant, if planted at the same time, make a good succession to each other.

CABBAGE—The main crop for spring should now be sown, so as to get good plants for putting out at the end of September.

CELERY requires frequent attention in the early stages of its growth, clearing away all suckers and useless growths from the base, and pushing on the growth of the main stem with frequent applications of liquid manure.

HERBS should be cut and dried, so as to give the plants time to make a good lot of fresh growth before winter.

LETTUCE AND ENDIVE.—Planting out for winter use and sowing for spring crops now needs frequent attention, as the supply for several months hinges on the use made of the next few weeks.

LEEKS should be got out without delay, as the crop of spring-sown Onions is sure to be light, and good Leeks will be in demand in spring. Trenches prepared as for Celery answer well for Leeks.

ONIONS.—This crop sown in autumn is in many places much less liable to the attacks of the Onion-fly than are those sown in spring. The Giant Rocca and the Tripoli varieties are especially suited for present sowing.

PARSLEY.—If not already sown no time should be lost if plants strong enough to supply any quantity for winter are to be grown. A position where it can be sheltered in very severe weather should be selected.

POTATOES.—The lifting and storing of all those that are ripe enough, as many kinds show a

The true Auvergne Pea.

decided inclination to grow out, in which case the first crop is spoiled and the second does not have time to mature. The best course to take directly sowing commences is to lift the crop at once and then crop the land with something else.

SPINACH.—This is one of the quickest of all green crops to attain a useful size, and the round summer sort sown now rather thickly will yield a good supply until severe weather sets in, and for the supply in winter and spring the prickly-seeded variety should be sown thinly and allowed to attain a good size before any foliage is plucked off.

TURNIPS will be especially useful in the coming winter; but if they are to attain a good, useful size the seed should be got in at once. The hardy White Stone is the best.
